10192. What I want to ask you is this: Do you think that licences and certificates under the Act ought to be granted to physiologists who have not any medical qualification?—Certainly. If you are not to grant them to physiologists who have not a medical qualification you would eliminate some of our most eminent physiologists.

10193. The difficulty is if a man has not a medical qualification what guarantee have you of his qualifications?—You have the guarantee of those who sign the licence and certificates, and of the director of the laboratory where he is to work. There is no instance of private work in private laboratories. Some of the very men I have had to do with have had no medical qualification. One of the most eminent workers in my own laboratory at the present moment is not a medical man, he has gone through no medical mill, and has no medical qualification—Dr. F. A. H. Marshall; he is a doctor of science, but he is one of the best experimenters I know. There is further the very eminent instance of the Professor of Physiology of Cambridge, and Dr. W. B. Harvy, also of Cambridge.

10194. None of whom have medical qualifications?—None of whom have any medical qualification at all. Physiology is only accidentally and incidentally a medical science; it is the science of life, and as medicine depends upon life, physiology has come to be included with medicine; but it must be treated as an independent science, and to exclude anyone on the ground that he has no medical qualification is to my mind ridiculous, for if a man has special knowledge of a subject and a special qualification for working at it, what more is required? And when one can adduce instances of men who have advanced the science so materially as those whom I have instanced, the objection is a *reductio ad absurdum*.

10194A. The next point I want to put to you is this. You mentioned certain experiments of your own on dogs, but I did not quite catch the number of dogs that you experimented upon. You performed two experiments without anæsthetics. How many did you perform with anæsthetics?—36 altogether—two without anæsthetics and 34 with anæsthetics. A certain number of those were not actually experimented on because they died whilst being put under the anæsthetic.

10195. And as the results of the experiments on those animals, in your opinion and that of other competent people, you have discovered a more fruitful method of resuscitating the drowned?—Yes.

10196. Has that method been in any way communicated to the Royal Humane Society?—It was only communicated by my having sent a copy of the paper to the secretary—in no other way. It is adopted by individual instructors in various parts of the country. I think it is unfortunate that the Royal Humane Society, the Life-saving Society, and the National Life Boat Institution have none of them taken it up, although it is well known to physiologists, and is becoming widely known to medical men. But societies like those are apt to fossilise; it is very difficult to get anything new instituted in connection with them. They have all their instructors trained in the old methods, they have all their leaflets printed, they do not know that one method is any better than another, and they have no means of judging.

10197. As a matter of fact, your method is easier to teach?—It is very much easier to teach.

Mr. E. A Schäfer, LL.D., SC.D., F.R.S.

12 June 1907

10197A. And much easier to practise?—And much easier to practise. It can be done by one man or one woman, or even a boy or a girl; it requires no physical strength. I believe many lives would be saved if it were generally known, because it can be applied so promptly and easily.

10198. (*Chairman.*) By anybody?—Yes; too much time is lost by the present methods, with all their preliminary proceedings—laying the patient down, turning him over, pulling out the tongue, undoing garments, and so on, when every second is of importance.

10199. (*Sir Mackenzie Chalmers.*) I may take it generally that by the sacrifice of 36 dogs we have a much more prompt means of restoring the drowned, which may in time save thousands of lives?—I believe that is so.

10200. As regards dogs themselves, I believe in Edinburgh superfluous dogs are destroyed by drowning?—They used to be destroyed by drowning; they are now destroyed by suffocation, I believe. I think they are put into a chamber with coal gas.

10201. So that at any rate the two dogs which were not under anæsthesia simply suffered the common death of superfluous dogs?—Yes.

10202. I noticed that in your statement you said that as regards new drugs, drugs must be first tested on animals?—Yes.

10203. We have had evidence to the contrary, and I want you to develop that a little one way or the other. We have been told that you can draw no inference whatever from the operation of a drug on an animal as to its operation on man. What is your observation with regard to that?—If you take a drug that you know nothing about, and administer it to a man, first, there is a certain element of danger, and, secondly, you can only judge of its action upon man by external signs, whereas upon animals you can judge very accurately its action on different organs of the body. You cannot do that on man. Take a drug which is supposed to act on the liver; we know that many drugs are supposed to act on the liver, and are called cholagogues; when tested upon animals, that many are not cholagogues, that they have no action on the liver; and yet for scores of years these drugs may have been administered in diseases of the liver with the idea of stimulating the liver to action, which idea, when subjected to the test of experiment, immediately vanishes.

10204. In the case of an experiment upon an animal, you verify the experiment by a post-mortem examination?—Whenever it is necessary.

10205. When applied to man, you would hardly like to test the experiment in that way?—No.

10206. We were told by a gentleman who represented homeopathy the other day that among homeopathists all experiments were made upon man, and not upon living animals. Do you think there is any danger in that?—I do not think there is any danger in the doses that homeopathists give.

10207. But in gradually increasing doses, I am afraid you would not like to do it on human life?—I think it might be all right, but one can never know with any new drug what dose might be poisonous.

10208. (*Chairman.*) The witness said that in testing a drug they did not use homeopathic doses; they used the drug in its ordinary form, and tried it as high as they could?—I am afraid I am no authority on the subject of homeopathy, but I would put an extreme case: Suppose a new drug having such a powerful action as cobra venom, and suppose you tested it in ever so small a dose upon a man, it would probably kill him.

10209. (*Sir Mackenzie Chalmers.*) We have heard a good deal for and against experiments made before students. In your opinion it is essential, to complete the education of a man who is going to practise as a doctor, that he should see certain experiments on animals?—That is my very strong opinion.

10210. I wanted to ask you this, further. It has been alleged that witnessing experiments on animals has a demoralising influence on students, and tends to make them inhuman. From your 37 years' experience as a teacher, what do you say to that?—I say that it is absolutely without foundation. The men I know best are the men who have been my assistants, who have been engaged as students and as teachers in operating upon animals. I should say that amongst all my friends there are none more humane than these who are constantly engaged in experimenting upon animals. So far as the effect upon students is concerned, it is obvious that what you have mentioned cannot be the case. The great mass of medical men who are turned out nowadays have seen experiments on animals—they certainly have at Edinburgh, for my predecessor showed many more experiments than I do, and hundreds and thousands of students passed through his hands, and I have not heard that the Edinburgh medical graduate is more callous than any other medical man who has not seen experiments on animals.

10211. To Dublin medical men experiments were denied for some years?—Yes, they were not shown in Dublin for many years; I do not say that those gentlemen are not more tender-hearted than others, but I have no evidence of it.

10212. It has been suggested that by seeing these experiments certain individuals, at any rate, get a desire to perform cruel experiments. Have you ever known an instance of that?—Never.

10213. It has further been suggested to us that in these demonstration experiments, as well as others, very light anæsthesia is practised. Is that according to your experience?—That is certainly contrary to the fact. I have very considerable experience of demonstration experiments, and I know as a matter of fact the great danger, in our experience, is the loss of the animal from over-anæsthesia. We are very careful that there shall not be any sign of movements, because that might be misinterpreted by the students. Although we ourselves know that movements do occur in cases of anæsthesia—every surgeon knows that—it is possible that a young student might not understand it. He knows it perfectly well after he has been in the operating theatre.

10214. I do not know if you have read Miss Lind-af-Hageby's evidence?—I read the second part of it while I was waiting upstairs.

10215. She apparently witnessed a good many demonstration experiments, and she told us that continually there was movement in the animals?—I do not know. I think that one experiment that she witnessed was on a choreic dog. There was, of course, movement in that.

10216. Would an anæsthetic stop the chorea?—I do not know; I should think not that form of chorea. Of course, movement invalidates experiment. You cannot work properly with movements; you are liable to have your apparatus injured.

10217. At any rate, in your laboratory during your 37 years' teaching, did the animals make purposive movements and struggle?—Certainly not; never.

10218. You may, I suppose, get movements when you are killing an animal?—If you kill the animal by pithing, you would have movement of muscles, which would not be voluntary movements, but simply due to excitation of the motor nerves that you were cutting through. But the usual plan is to kill the animals with chloroform; in fact, that is the invariable plan with us.

10219. You push it rather further?—Yes, we either do that or inject chloroform into the blood vessels, which kills them immediately.

10220. Miss Hageby spoke to hearing cries from some of the animals seen under demonstrations. Is that possible?—It has never happened when I have been present. I should think it is quite impossible.

10221. In your 37 years it has not happened?—No, never.

10222. Do you agree with the evidence that we have had, that when an anæsthetic is administered sensation disappears before power of movement disappears?—That is quite well known to be the case.

10223. Do you further agree that power of movement returns before sensation returns?—That is also well known.

10224. Is that sensation generally, or is it sensation to certain stimuli?—I should say sensation generally. There are higher and lower forms of sensation. The higher forms of sensation are, of course, the last to return.

10225. (*Dr. Gaskell.*) When you say that you have never heard any cries in your experience, have you

never heard a sound coincident with respiration of a sort of whining character; I mean to say, through the respiration tube, principally through a little blocking in the tube?—Yes, that may occasionally occur if there is mucus in the tube.

10226. (*Sir Mackenzie Chalmers.*) A sort of râle?—Yes. I suppose by this time one hardly considers any member of this Commission as belonging to the laity—they must know by this time much about the subject; but I may be permitted to explain that it is very well known that patients when they are taking chloroform, although they are perfectly without sensation, make all sorts of noises, sing, scream, and make ridiculous utterances without being the least conscious of it, and without having any memory of having done so when they wake up. And in the same way one of the symptoms which is observed when a dog is put into a box or given chloroform is, just before he has become profoundly anæsthetised, a succession of loud noises, not exactly a bark, not exactly a whine, and not exactly a howl, but peculiar noises which might be taken by anybody who was not an expert on the subject to indicate that the animal is under the influence of pain. It is nothing of the sort at all. It belongs to the same class of noise that patients make who sing and cry out when they are going under chloroform, just before they are completely under its influence.

10227. (*Chairman.*) Does that differ with different dogs as it does with different human beings?—Yes, very much—some are perfectly quiet, and others make a great deal of noise. I do not like to hear it myself, and I am afraid that the students who are not always in the room at the time might sometimes think that we are ill-treating the dog, whereas, as a matter of fact, the animal is simply in a box with vapour of chloroform being pumped into it.

10228. (*Sir Mackenzie Chalmers.*) Do you use pure chloroform or A.C.E.?—I do not use A.C.E. I use chloroform with a small proportion of alcohol, one-tenth of alcohol; I find this quite as efficient as A.C.E., and simpler. With A.C.E. you introduce three drugs into the animal. When you use an anæsthetic you must introduce a drug, and it is better to reduce the number.

10229. Have you ever experienced any difficulty in giving an anæsthetic to dogs and keeping the dogs under anæsthesia?—In my experience dogs are more easy to anæsthetise than any other animal. One is much more liable to lose a rabbit than a dog with chloroform, especially if you give the dog a prior dose of atropin. It is very rarely indeed that I have lost a dog after introducing atropin. That would be due to sheer carelessness in the anæsthetic being pushed to an extraordinary extent. We cannot in a laboratory always have the services of a skilled anæsthetist, and this makes a great deal of difference; we are sometimes obliged to ask a person who is not a skilled anæsthetist to give the chloroform. And, as everybody knows, anyone who is not a skilled anæsthetist is much more likely to kill a patient than a skilled anæsthetist, because he will push the anæsthetic too far if he sees the least movement, and thinks the patient is coming out.

10230. In the case of an animal if you push the anæsthetic the worst that can happen is that the animal dies prematurely?—Yes.

10231. So that you can push the anæsthetic better with an animal than with a human being where you wish the man to recover?—That is so. There is the element of anxiety in giving an anæsthetic to a patient. That is not the case with an animal, because it does not matter seriously if it dies; consequently you push it more than you do with a patient.

10232. Then there is one other small point. We had some evidence last time, I think, as to various ways of pithing frogs, and it was suggested to us that the spinal cord might be severed from the brain and purposive movements would still go on; and, although the spinal cord is severed from the brain, the frog would feel pain. What is your opinion as to that?—I think all the evidence that we have is contrary to that. I think the evidence from man, if a man is to be compared with a frog, is conclusive.

10233. When once you have severed the spinal cord from the brain of man?—There is no sensation below the point of severance. The fact that movements are produced is well understood. You might just as well say that the tail of a newt, which continues to writhe and perform spontaneous movements, has all consciousness and volition left in it. No one for a moment would hold such a thing.

Mr. E. A. Schäfer, LL.D., SC.D., F.R.S.

12 June 1907.

10234. (*Dr. Gaskell.*) That is just what they do say?—I mean no expert authority.

10235. (*Sir Mackenzie Chalmers.*) Or a person who has studied the subject and is capable of forming an intelligent opinion?—No.

10236. As regards the use of atropin, has that been applied as yet to human beings?—It has.

10237. In conjunction with an anæsthetic?—Yes; Dr. Scharlieb, who did the experiment with me, and is an expert anæsthetist in London, tells me that he would use it always, but he cannot always get surgeons to agree that it shall be used.

10238. Do you think, as the result of your experiments on animals, that a possible improvement has been made in administering anæsthetics to human beings which may have the result of saving life?—Yes; but I would not take the credit of this to myself. It was first shown by the experiments of Dr. Embley and Dr. C. J. Martin, of Melbourne, who is now at the Lister Institute, that the fatal effect of chloroform is usually produced on the vagus, and that cutting the vagus (and giving atropin has exactly the same effect as cutting the vagus, because it cuts off the influence of the vagus from the heart) entirely abolishes this inhibitory effect of chloroform. So that although I have carried the giving of atropin into practice and I have recommended that it should be given in all cases of anæsthesia, I do not wish to take credit for the discovery of the fact.

10239. Have you discovered any dangerous results from giving a dose of atropin when given with an anæsthetic?—No, none whatever; the dose required is very small. In a large dog, for example, 1-50th of a grain of atropin is quite enough to keep the animal in a safe condition for three hours. In the case of man, I do not think a larger dose is required, because man is more susceptible to atropin than the dog.

10240. Of course the atropin itself has no effect on the sensation of pain or on the anæsthesia which is produced?—No.

10241. Then there is one other question I want to ask you as regards the Home Office Administration. You agree that under the Act the Home Secretary can suspend or disallow a certificate?—Yes.

10242. Does it not follow from that that he may impose conditions?—I do not know that it does follow from that, but he can impose conditions on the licence.

10243. I am speaking now of a certificate?—There is nothing in the Act to say that he shall alter the certificate. The certificate is granted by two authorities, and there is nothing in the Act to say that he shall alter the certificate.

10244. But an alteration, I suppose, is alternative, and possibly preferable to disallowing it?—When he puts himself in the position of the grantors, I do not think that he is right. He makes himself an expert authority on the subject.

10245. At any rate, he is the person responsible to the public for the operations that go on?—I think under the Act it was intended that the grantors should be responsible to the public. Otherwise I do not see the use of them.

10246. The Secretary of State has to answer in Parliament, which the grantors have not to do?—Yes, of course.

10247. Then as regards the place of the experiment, I did not quite understand your suggestion. You thought it was unnecessary to keep the animals in the place?—I do not think it is of any importance that they should be kept in the same laboratory.

10248. Is it not simply for the purpose of inspection; that if the animals could be moved about the inspector would not be able to inspect them?—I think the inspector would be able to inspect them if they were removed to another registered place.

10249. You would confine your amendment of the law to allowing them to be moved from one registered place to another registered place?—As for example, from a laboratory in town to a farm in the country, which might also be registered for the keeping of animals.

Mr. E. A. Schäfer, LL.D., SC.D., F.R.S.

12 June 1907.

10250. (*Chairman.*) Is there anything else you wish to bring before us?—Something has been said about the importance of clinical observation, and as to the possibility of clinical observation superseding experiments altogether. I should like to illustrate the defects of mere clinical observation unassisted by experimentation on animals by a statement regarding the discovery of the active principle of supra-renal extract. Dr. George Oliver had been making a large number of clinical observations upon the effect of various organ extracts upon the circulation, but had been unable to arrive at any definite conclusions regarding them. Amongst these was extract of supra-renal capsule, extract of thyroid gland, extract of brain, and so on. He consulted me as to what steps might be taken to arrive at a clearer understanding with regard to their action, and I invited him to investigate their physiological action along with me upon animals in the laboratory. This we proceeded to do; and the result of the investigation was that the majority of the extracts from which he supposed that he had obtained definite results in man gave no indications of physiological activity; whereas, on the other hand, the extract of supra-renal capsule gave such manifest indications of activity that it was quite clear a very important principle was contained within this organ. The properties of this principle we then proceeded to work out, and the result of the investigation led to the discovery of adrenalin, which has proved of immense physiological, and will in all probability prove of great therapeutical and clinical importance. I would also point out that two methods must always be employed in physiology in investigating the functions of an organ. The first is the method of stimulation or addition; the second, the method of removal or subtraction. This may be illustrated by experiments upon such organs as the ductless glands. If we again take the case of the supra-renal capsule, we find that the effects of addition are, first, increased contraction of the blood vessels; second, increased action of the heart; third, contraction of the uterus, and, generally, a tonic influence in all parts supplied by the sympathetic nerve. If, however, the addition be excessive and prolonged, certain chronic effects are produced, the most striking of which is an atheromatous condition of the arteries, which may eventually lead to aneurism. The effect of removal, on the other hand, is in most animals death within a few hours with symptoms of extreme vascular and general muscular weakness, these symptoms being similar to those which result from the gradual destruction of the gland by disease. So again with the thyroid body. The effects of addition or increase of its secretion are the production of a condition of nervous excitation, and certain ill-understood effects on nutrition. The effects of its removal vary in different species of animals. In some the result is *nil*, possibly owing to the fact that there may be small accessory glands of the same structure and function left behind in the body. In other cases, on the other hand, there is a general condition of malnutrition of the connective tissue produced, together with depression of the functions of the higher parts of the brain, sometimes combined with an excitable condition of the lower levels of the nervous centres, leading to increased reflex action and even to convulsions. All these effects can be counteracted by thyroid administration. The second method of experimentation necessitates the keeping of the animal after removal of the organ for days, weeks, or months, in order to understand the condition of the experiment; and the animal used must be one the organs of which are generally similar to those of man, if the conclusions which are drawn from the experiments are to be applicable to man. On this account, and for this second method of experimentation in particular, it is in very many instances essential that dogs should be the subject of experimentation. This is especially true for work upon the alimentary and glandular systems, whereas for work upon the central nervous system monkeys as well as dogs require to be used.

TWENTY-THIRD DAY.

Wednesday, 19th June 1907.

PRESENT:

The Right Hon. The Viscount SELBY (*Chairman*).

Colonel the Right Hon. A. M. LOCKWOOD, C.V.O., M.P.
Sir W. S. CHURCH, Bart., K.C.B., M.D.
Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir J. McFADYEAN, M.B.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. A. J. RAM, K.C.
Mr. W. H. GASKELL, M.D., F.R.S.
Mr. J. TOMKINSON, M.P.
Mr. G. WILSON, LL.D., M.D.

Captain C. BIGHAM, C.M.G. (*Secretary*).

The Hon. STEPHEN COLERIDGE, called in; and Examined.

Hon. S. Coleridge.
19 June 1907

10251. (*Chairman.*) You are Secretary of the National Anti-Vivisection Society, I believe?—No; I am Honorary Secretary; Mr. Stewart is the Secretary.

10252. How long have you held that position?—I have been Honorary Secretary for ten years—since 1897.

10253. You have been good enough to send us a short note of the subjects on which you desire to give evidence. There is only one point that I wish to call your attention to—that is, your reference to the ethical question. I only want to say as regards that that we have had a great deal of evidence upon that question, to which we attach due importance, I hope, and that we have become pretty well possessed of the opinions and views which are held upon it. We are anxious to have the views of your Society upon it, too; but I hope that in consideration of the great amount of evidence we have heard, you will put that part of your case as briefly as possible?—I have prepared a very short statement, which I think I might as well read, because it will, at any rate, afford the Commissioners material for cross-examining me upon it.

10254. Let me ask you first about your Society, so as to have it on the notes. When was it founded?—About 1875 or 1876; just before the passing of the Act.

10255. And it is a very large Society?—Yes, by far the largest in the world.

10256. I dare say you can tell us how many members there are?—I have got the figures here. To illustrate its increasing importance, I give the income for each five years since 1887: £8,651 for the first five years; £15,712 for the next; £26,352 for the next; and £36,097* for the last five years, showing a large increase.

10257. Does membership involve a subscription?—Yes. We have a great number of honorary members, whom we have elected, and a very large number of our branches have very large numbers of members each; but some only subscribe a shilling, and such small subscriptions, so that it is impossible for us to ascertain the names of everybody.

10258. You have not a fixed subscription?—Yes, for headquarters—10s.

10259. And I may take it, I suppose, that while the evidence is your evidence, it will represent generally the opinions of your society?—Yes; whenever I wish to dissociate myself in any way and give a personal note to my evidence, I should say that I was not in agreement. But generally, I am in agreement with my society.

10260. I think now you had better give us your statement, and you will allow me, if I think you are getting off that line at all, to interrupt you?—Yes. I assume that it is not exactly like a court of justice. I have put down, so that there should be no question about the claim of my society really to represent the anti-vivisectionists, the force and strength of the other societies, and, without desiring in any way to set up an odious comparison, I think it is proper that I should say that the income of the London Anti-Vivisection Society, which is next in importance to the National, amounts to about a quarter, and that the income of the British Union amounts to about one-eighth of that of my society. There is the Manchester Society for the Protection of Animals from Vivisection, with an office at 9, Albert Square, Manchester, and an annual income from donations and subscriptions of £205 3s. 8d. There is the Parliamentary Association for the Abolition of Vivisection, with an office at Parliament Mansions, Victoria Street, London, and an annual income from donations and subscriptions of £174 9s. 6d. I think you have had four witnesses from that society. There is the Bristol and West of England Anti-Vivisection Society, with an office at Bank Chambers, Clifton, Bristol, with an annual income from donations and subscriptions of £164 10s. 9d. There is the Friends' Anti-Vivisection Association, with no official address, and an annual income of £118 5s. 5d. There is an Electoral Anti-Vivisection League, with an address at 92, Ladbroke Grove, W., and an income of £83 6s. 4d. There is the Society for the Abolition of Vivisection, founded by the late Mr. Jesse, who left it some money on condition that it never associated itself with any other Anti-Vivisection Society. This exclusive association has an income from donations and subscriptions of £60 9s. 6d. a year. It also enjoys the interest from Mr. Jesse's bequest. I have ascertained that there are 79 members of that society. Then there is the Scottish Society for the Suppression of Vivisection. I have asked for their last year's report, but up to date I have not received it. That is another very old Association, but the membership is not nearly so large as is the membership of the Scottish branch of my own society. There is a World's League of Opponents of Vivisection, which addressed its letters from 32, Sackville Street, which, according to the published report, has 63 members, with a total yearly subscriptions and donations of £56 0s. 1d. There is a Church Anti-Vivisection League, with no official address in its yearly report and an income of £54 4s.† There is the Bolton Anti-Vivisection Society, with no official address, and an annual income from donations and

* *Mr. Coleridge subsequently wrote to say that this sum included the "Coleridge Defence Fund."*

† *The Secretary of the Church Anti-Vivisection League subsequently wrote saying that the League had an official address and an income of* £60 15*s.* 2*d.*

Hon. S. Coleridge.

19 June 1907.

subscriptions of £39 1s. There is a Society for United Prayer for the Prevention of Cruelty to Animals, especially with regard to the practice of vivisection; it appears to have no office; its income is £33 16s. 11d.* There is the Pioneer Anti-Vivisection Society with no official address, and an annual income of £6 17s. 6d. This exhausts the Anti-Vivisection Associations as far as I am aware, and I think leaves no doubt of the justice of the claim of my Society to represent the cause of anti-vivisection in this country. I cannot give you the exact membership of our own Society. The Birmingham Branch is very large, but they subscribe, some of them, only a penny or twopence, or sixpence. The first striking achievement of my Society, with which I had the honour to be associated, was the prevention of a public meeting held at the Mansion House in 1889, the object of which was to start a fund to erect a Pasteur Institute in England. We prevented that public meeting taking place, and the result was that no Pasteur Institute was set up. England to-day is, I believe, one of the few European countries of importance that is spared a Pasteur Institute, and in England there is no rabies. Another remarkable achievement of my Society has been the long agitation against the diversion of Hospital Funds in London to Medical Schools, which are places registered for vivisection under the Act of 1876. We conducted that agitation with such persistence that King Edward's Hospital Fund were at last obliged to appoint a Committee, composed of Sir Edward Fry, the Bishop of Stepney, and Lord Welby, to inquire into the charges we had publicly formulated. That Committee, after hearing evidence from all parties, made a report which confirmed the statements we had published. It was stated that where money was paid over to schools out of hospital funds, the schools remained "debtors to the hospitals in respect of these pecuniary contributions made to them," and recommended that in future the funds of hospitals and schools should be kept entirely distinct.

10261. That is the particular statement that they confirm?—Yes, that is so. In spite of this remarkable report, however, no school has repaid a penny of the money diverted to it from the hospital; and in some cases the deliberate diversions of money subscribed for the sick poor to schools registered for vivisection continues, with the knowledge of and without any effective protest from King Edward's Hospital Fund, which thereby contemptuously disregards the recommendations of the distinguished Committee appointed by itself. I present to this Commission a publication, for which I take the entire responsibility, briefly called my "Guide to the Charitable," which sets out the financial diversions of hospitals to schools up to the present date (that is for purposes of cross-examination). In the last few years we have conducted public controversies in the "Fortnightly," "National," and "Contemporary" Reviews, and many other periodicals; we have held mass meetings in the largest halls in London; we have founded thriving and earnest branches all over the three Kingdoms. We have conducted a Parliamentary campaign in favour of the Bill I have drafted, and have kept the question of vivisection so prominently before the public that it has been found necessary to appoint this Royal Commission to inquire into it. We claim to represent the consensus of opinion of almost all the greatest names that have adorned the history of England in the field of thought. In Cymbeline the Queen suggests to Cornelius, her doctor, a process of investigation similar to the modern inoculator's experiments under Certificate A. He says:—

> "I will try the forces
> Of these thy compounds on such creatures as
> We count not worth the hanging (but none human),
> To try the vigour of them, and apply
> Allayments to their act; and by them gather
> Their several virtues and effects."

Upon which Cornelius, in a spirit far different from the modern vivisector, replies:—

> "Your Highness
> Shall from this practice but make hard your heart:
> Besides, the seeing these effects will be
> Both noisome and infectious."

From which passage we may claim the greatest name in England and the world for our cause. And it may be interesting to the Commissioners to know that my attention was first called to this striking passage by my late friend, Sir Henry Irving, himself an ardent anti-vivisectionist. Andrew Marvel, in a striking passage, says:—

> "Heaven's King
> Keeps register of everything,
> And nothing may we use in vain;
> E'en beasts must be in justice slain."

Dr. Johnson dismissed the vivisector with one crushing sentence:—"What is alleged in defence of these hateful practices everyone knows, but the truth is that by knives, fire, and poisons, knowledge is not always sought, and is very seldom attained. I know not that by living dissections any discovery has been made by which a single malady is more easily cured. And if the knowledge of physiology has been somewhat increased, he surely buys knowledge dear who learns the use of the lacteals at the expense of his own humanity. It is time that a universal resentment should arise against those horrid operations, which tend to harden the heart and make the physician more dreadful than the gout or the stone."

10262. Where is that from?—I can find it you; it is a fine passage I think. And the cause of anti-vivisection counts, and has counted, among its supporters, living and dead, Cardinal Manning, Lord Tennyson, Robert Browning, John Ruskin, Thomas Carlyle, James Anthony Froude Freeman, the historian, the great Lord Shaftesbury, who was the first president of the society, and filled that office till he died, George Meredith, member of the Order of Merit, General Booth, the Lord Chancellor, Mr. John Morley, member of the Order of Merit, Cardinal Gibbons, James Martineau, Spurgeon, Lord Brampton, Wagner, Leslie Stephen, Sir Edwin Arnold, Mark Twain, Tolstoy, Victor Hugo, Dean Stanley, and a host of distinguished men and women in every walk of life whose opinions upon a matter of conduct cannot be disregarded, and Her late Majesty Queen Victoria, who was in favour of the total abolition of vivisection. As the humble spokesman of this constellation of great writers, I feel the extreme inadequacy of my powers fitly to give voice to their solemn condemnation of painful experiments on animals as a practice repugnant to the promptings of humanity and degrading to mankind, but I desire to be permitted to say that, inasmuch as four generations of my family before me have earnestly supported this humane cause, my own convictions have come down to me as a consecrated inheritance. My society desires to see vivisection totally abolished by law, but it will strive for and accept any measures that have for their object the amelioration of the condition of vivisected animals. We are guided in our policy inside Parliament and without by the consideration that we are the faithful representatives of the hapless creatures in the laboratories who cannot speak for themselves. We base our objections to vivisection as sanctioned and protected by the Act of 1876 on the plainest moral ground. We hold and invite the Commissioners to maintain that the right of man to take animal life involves the duty of taking it with as little accompanying pain as possible. We are prepared to show that under the existing law there is no limit to the agony that may legally be inflicted upon animals, and we abominate a statute that authorises gross inhumanity. We say that to keep an animal alive and torture it is a wicked act, that no profession of lofty motives will ever make that wicked act right; if this were not so, it might be right to rob a bank with the professed intention of devoting the stolen money to the services of the poor. The whole question of man's rights over and duties towards the helpless animals given into his dominion by the Ruler of the Universe, is a moral question, and has nothing to do with science. And if all the benefits so boldly claimed as having been conferred upon physiology by this practice were in deed and truth so received, the issue would remain solely a matter of conduct upon which the least scientific of us has as much a right to be heard as the most expert vivisector; and we maintain that if there be any cruelty inseparable from this particular science every thoughtful man who takes a wide view of human well-being must conclude that it is far better for us all to do without physiology than to be without pity. I have carefully read the evidence of Mr. Byrne on behalf of the Home Office, and as it stands it has, in my opinion, justified to the fullest extent the expressed and published conviction of my society, that the whole truth about the administration of the Act of 1876 by the Home Office could never be elucidated without cross-examination by counsel properly instructed.

---

* *The Secretary of the Society for United Prayer for the Prevention of Cruelty to Animals subsequently wrote to say that he Society had an official address and an income of* £89 0*s.* 8½*d.*

We should have preferred to substantiate the charges which it is our duty to make against those officials out of the mouth of Mr. Byrne, their representative; but as that is now apparently impossible, I shall endeavour, on behalf of my society, to prove the indictment we have drawn by unimpeachable evidence. (1) I am here to charge the Home Office officials with repudiating the most important duty deputed to them by Parliament, videlicet, that of protecting animals from unjustifiable suffering; (2) I am here to charge the Home Office officials with having constituted themselves the injudicial defenders of the vivisectors from criticism by my society in the past, and in their evidence tendered before this Commission; (3) I am here to charge the Home Office officials with having appointed inspectors who have displayed such bias that they have thought it their duty not to make detective efforts to protect animals from illegal treatment; (4) I am here to charge the Home Office officials with having made entirely disingenuous statements in their official utterances, and with having constituted themselves the mere spokesmen of the vivisectors; (5) I am here to charge the Home Office officials with accepting the suggestion made to them by some nameless adviser that to starve animals for days is not cruel when they must know perfectly well that if any one of them starved their own horses (if they have any), the nearest policeman could successfully prosecute them for cruelty to animals under Martin's Act; (6) I am here to charge the Home Office officials with suppressing in the Annual Parliamentary Return the names of those who take upon themselves the very grave responsibility of signing the certificates exempting licensees wholly or in part from the obligation to employ anæsthesia in their vivisections, although in the Report of the former Royal Commission we find this clear direction: "We recommend that his (the Home Secretary's) advisers be from time to time elected and nominated by himself. Their names should be made known to the profession and the public." (7) I am here to charge the Home Office officials with shielding the names of such licensees as they know to have broken the law, although the former Report contains these words:—"Abuse of the power conferred by the licence must, of course, render the holder liable to its withdrawal, but this will involve great disgrace," a phrase that clearly indicates that the framers of that Report contemplated the publication of offenders' names, for no great disgrace can appertain to a secret remonstrance of a secret withdrawal of a licence. (8.) I am here to charge the Home Office officials with preparing for the Home Secretary evasive and insufficient replies in the House of Commons to plain questions on the administration of the Act, and with making evasive and insufficient replies themselves in official correspondence with my Society, and with leaving perfectly proper questions unanswered altogether. (9.) I am here to charge the Home Office officials with putting forward annually a Parliamentary Return in which it is asserted, on the official authority of the Government Department, that not a single experiment in thousands inflicted upon animals in Great Britain with its permission can be specified as entailing any pain at all, when all the while this plausible assertion is based upon no better evidence than the bare assertion of the vivisectors themselves, who are not to be expected to report themselves cruel men. (10.) I am here to charge the Home Office officials with placing a certain vivisector year after year beyond the reach of the safeguards erected by the Act to protect animals from illegal treatment by licensees, by giving him permission to vivisect in private places, thereby placing him beyond the possibility of legal inspection; because by Clause 10 of the Act of 1876 the inspector has no right of entry into, or inspection of, any unregistered place.

10263. What is the name of that particular person?—Victor Horsley. (11.) I am here to charge the inspectors certainly, and the Home Office officials apparently, with having made no inquiries, public or private, into the vital question of the character for humanity of the licensees to whom they have delivered over the animals to be vivisected. Although those officials must be aware that the Report of the Royal Commission in 1876 contained this pregnant warning: "It is not to be doubted that inhumanity may be found in persons of very high position as physiologists," and although the Act of 1876 placed upon the Home Secretary the tremendous responsibility of personally protecting animals from that undoubted inhumanity. (12.) I am here to charge the Home Office officials with having placed themselves in improper private confidential relations with a private society composed of supporters of vivisection entitled to no more consideration than the National Society composed of opponents of vivisection.

10264. (*Sir Mackenzie Chalmers.*) Would you mention that society's name?—It has been called in the House of Commons the Society for the Propagation of Scientific Research; its real title is the Society for the Advancement of Medicine by Research. These manifold charges, which I am prepared fully to substantiate before leaving this Commission, justify, in the opinion of my Society, the imputation, which we do not fear to make, that the Act which was intended by Parliament to constitute the Home Secretary the guardian of the vivisected creatures, has been so administered that this solemn responsibility has not been impartially fulfilled. So safeguarded are the vivisectors from the possibility of anybody but themselves knowing what happens in the laboratories, that the opportunity of raising the impenetrable veil that covers their doings can never occur but through their own initiative. Through the hasty temerity of Mr. Bayliss, who brought an action against me, we did for once ascertain from the evidence of that vivisector and his friends the history of the life and death of one at least of the victims of the laboratory. Their evidence proved that under the present law a deep incision can be made into the body of a live dog, and it can be deprived, by the tying up of a duct in its inside, of the proper use of one of its internal organs; it can then be sewn up again and put in a cage, and left in that cage from December to February to see what the result would be of that operation upon it. In February it can be taken out of the cage and a fresh incision can be made into its body to see whether what has been done to it produces inflamation or not. The wound can then be closed up again with a pair of steel forceps. Then with the steel forceps closing up this wound, the living dog can be handed over to a second vivisector, who proceeds to fasten it down tight on to a board and to open its neck with another deep incision, exposing the gland; he can then fix little pipes on to the end of the arteries, he can put a tube into its windpipe, and attach electrodes to its cut-out nerves. The dog in that condition can be tied down on that board for about an hour, and then handed over by this second vivisector to a third operator, who finally puts an end to the miserable dog's life by plunging a knife into its heart. Now the anæsthetics during these prolonged and fearful mutilations can legally be applied by an automatic pump in another room, connected to the dog under the floor by a tube, and this pump, on which alone the insensibility of the dog depends, can be left in the sole charge of a laboratory boy. The vivisectors say that this automatic pump is sufficient to maintain the unconsciousness of the dog throughout the whole operation; but, inasmuch as the dog cannot tell us whether it is unconscious or not, and as no analogy can be set up with human anæsthesia, because no surgeon in his senses would attempt to anæsthetise a man or a woman with an automatic pump in another room under the management of a laboratory boy. I maintain that we may reasonably refuse to accept the opinion of these vivisectors that such means are efficient to maintain total unconsciousness. Further, we have a perfect right to hold the opinion—and we do hold it—that the sufferings of the dog between these vivisections when it was in that cage were very grievous. To procure this priceless information from the vivisectors themselves in the witness-box cost altogether about £5,000; but in my opinion this revelation of what vivisection really is in this country under the present administration of the law was well worth the expenditure. As to the assertions of the vivisectors who have come before you that they individually have never inflicted pain in their experiments, I am not here to ask you to believe them or to disbelieve them; but I assert that the present law, as administered, cannot possibly protect animals from the extremest torture at the hands of any licensed vivisector who happens not to be humane. The comfortable hypothesis of the Home Office appears to be that a person who applies for a licence and receives certificates is necessarily humane. To that hypothesis we distinctly demur. Neither the dignatories of the physiological circles nor the vivisectors who are banded together in the private society for the advancement of their practices, nor the inspectors appointed by the Home Secretary, testify to the personal character or humanity of the applicant for licences

Hon. S. Coleridge.

19 June 1907.

and certificates. They aver nothing but the applicant's scientific fitness. Scientific fitness is no guarantee of humanity, nor is the habit of cutting into living animals necessarily the concomitant of a tender heart. Therefore we assert that the present law and the present administration of it do not protect animals from the worst conceivable fate. We represent a growing volume of indignation against such a law and such an administration of it. There have been members of my society so moved by the hideous possibilities of the laboratories as to be hardly restrained from violence. The sufferings of dumb creatures appeal with overwhelming force to an ever-increasing proportion of our countrymen and countrywomen, and, as I believe, to those who are the truest judges of right conduct. I am reluctant to make a personal attack upon any vivisector; I have come here on behalf of my society to denounce a system and a practice rather than to expose individual barbarities. But I may perhaps be permitted to say that the permission recently given to a vivisector to drown, resuscitate, and drown again dogs without any anæsthetics, which have been already alluded to here, have been regarded by my society with particular detestation.

10265. (*Colonel Lockwood.*) That is Schäfer you mean?—Yes, Schäfer?—I know not how many thousand upon thousands of men, women, and children have been saved from drowning the world over by dogs since they became attached to mankind as their faithful friend. Not long ago I read of a dog that had saved ten lives from drowning, and perished in a gallant but unsuccessful attempt to save an eleventh. It seems to many of us an act that is degrading to humanity to reward all this splendid devotion by taking dogs and subjecting them to these horrid experiments, and it seems to me inexplicable that any man could be found to do such dreadful business. The physiologists tell us that they can learn more from the dog than from other animals. To that proposition we oppose no contradiction. From the dog we can learn courage, constancy, loyalty, steadfastness, faith, love; but it is not these qualities that interest the vivisector; it is the weight of its spleen or the pressure of its blood that elicits his curiosity, and he digs into its living body in his horrid quest. I desire to bring before the Commissioners the sixteen experiments performed by Dr. Crile in Sir Victor Horsley's laboratory, in one of which the foot of a dog was deliberately crushed "under incomplete anæsthesia." Apart altogether from the question of pain, this series of experiments, involving the most repulsive operations, in which every conceivable outrage is perpetrated upon bodies of the victims, have filled decent people who have faced their perusal with disgust and horror. I am here to say on behalf of my society that if physiology cannot be pursued without such loathsome practices it is high time it were abandoned. We are confident that we are expressing the feelings and sentiments of the vast majority of Englishmen when we assert that the mere power so to treat living creatures does not involve the justification of such treatment as a matter of conduct. The knowledge of what will happen to a dog when its feet are crushed in pincers and boiling water is poured into its inside seems to me, as a layman, as remote from any practical service to humanity as is the discovery of a variable star or the five hundred and sixty-eighth asteroid. But, looking through a telescope and tearing a living dog to pieces are very different human actions, and this fundamental difference must ever place physiology as now pursued in a degraded position altogether distinct from that of the noble sciences. Physical pain is perhaps not the worst evil that can afflict mankind. To us, "with such large discourse looking before and after," bodily pangs are less insufferable than remorse, ruin, jealousy, or a broken heart. But with animals this is not so; to them physical pain is the worst of all evils. They have no armour of the mind wherewith to summon to their aid an intellectual fortitude. They can look up to no martyr's crown, they cannot bring their miseries to the feet of a pitiful God. Therefore it is that our sympathies are so deeply moved by the spectacle of animal suffering, therefore it is that we say that to pursue knowledge through the agony of animals is an act only possible to a man whose heart is dead. If it could be proved that anybody's life had been prolonged by these practices our answer is that if the vivisectors could make us all live to be a hundred it would be a miserable exchange for an extinction of pity in the human heart. It is comparatively unimportant how long we live; what matters is, how we live. There is one more pathetic concomitant of vivisection which is totally ignored by the physiologists, but which I desire to enforce upon the attention of the Commissioners. Grievous and terrible as are we believe the physical sufferings now permitted by law to be inflicted upon dumb animals, this is not all for which the physiologists and the Act of 1876 are responsible. The knowledge that horrible mutilations may be daily and hourly executed upon the bodies of living creatures with no adequate security, for their insensibility makes very many humane people profoundly miserable, it rises day and night between them and their peace of minds, it haunts their lives waking and asleep, it deprives them of joy in this world which otherwise might be theirs. I am here to ask that this mental anguish, so immense in its aggregation, should not be regarded as of no account by this Commission. In all my reading of the writings of the vivisectors descriptive of the most appalling experiments, I have never met with a single expression of regret that such treatment of helpless creatures was a painful necessity, or a single word of sympathy with the miserable victims in their laboratories, and I am here to tell the Commissioners that the 300 odd vivisectors in the kingdom are responsible for a rising and widespread feeling of bitterness against the whole medical profession, with which in the public eye they are confused. This in the future may be not the least price the physicians of the country will find they have to pay for their supine acquiescence in vivisection as it is now allowed by law. The Commission by recommending Parliament to afford a real protection to vivisected animals have it in their power to check the spread of a deep and abiding enmity to a whole profession, which will be as deplorable as it will be inevitable if the law remains as it is. It will be observed that my Society has been forced to the conclusion that, by placing the interests of the animals in the hands of the Home Secretary, the framers of the Act of 1876, unwittingly, no doubt, made a fatal mistake. The Home Secretary has practically delegated much of his responsibility to the Home Office officials, who have in their turn delegated their responsibility largely to a private association of vivisectors called into existence for the very purpose of representing their own interests as opposed to the interests of the animals as represented by my society. And a state of things has thereby been created and maintained for years which we invite all impartial people to condemn as little short of a public scandal. What might have happened had a Home Secretary come into office who held the opinion that to inflict any amount of suffering was justifiable if it were claimed that science might possibly be advanced thereby, must be as obvious as deplorable, unless the solemn aspiration with which the Royal Commission of 1876 closed their Report is to be regarded as having been entertained in vain. "We trust," they said, "that your Majesty's Government and Parliament of this kingdom will recognise the claim of the lower animals to be treated with humane consideration." Under the present law what has happened in the past and what legally might happen in future fill those I represent with indignation and alarm; and we earnestly invite this Commission to consider with care and to recommend to Parliament the Bill which I have drawn, and which I now present to it. And now before I proceed to advance from these general statements to the production of the evidence for their support, it is my duty on behalf of my society to enter very respectfully my protest against the exclusion of the Press from this Commission, and the exclusion of counsel to represent our society. The ultimate publication of these proceedings will not contain much that the public may rightly claim to know, and of which the presence of the Press would have kept them informed. But my society have deemed it nevertheless to be their duty to direct me to bring their case before the Commission, and, of course, what I myself may say here is not said confidentially, but is intended to be entirely and with as little delay as possible public.

10266. (*Chairman.*) What are the matters of fact that you are proposing to deal with?—I now propose to deal with these charges which I bring against the Home Office seriatim. The first charge that I bring against the Home Office is that of repudiating the most important duty deputed to them by Parliament, viz., that of protecting animals from unjustifiable suffering. The Report of the Royal Commission of 1876 recommended that "Experiments upon living animals, whether for original research or demonstra-

tion, should be placed under the control of the Secretary of State." It further says: "The holders of licences should be bound by conditions, and breach of the conditions should entail liability to forfeiture of the licence." Now this is what I am emphasising: "The object of the conditions should be to ensure that suffering should never be inflicted in any case in which it could be avoided, and should be reduced to a minimum where it could not be altogether avoided." What I have to say about that is this: I maintain that when you are reading the old Act of 1876, it is essential to read it in conjunction with the recommendations made by the Commissioners who reported in 1876, and upon whose Report that Act was passed; and, therefore, I say that the Act of Parliament clearly laid upon the Home Secretary the duty of seeing that suffering should not be inflicted if it could possibly be avoided, and in fact placed the whole question of pain in his hands.

10267. (*Sir Mackenzie Chalmers.*) Would you give us the actual words you rely upon?—Yes—"the object of the conditions should be"——.

10268. No—the words of the Act, please; what are the words of the Act?—I am reading from the Report of 1876.

10269. The Report was afterwards followed by the Act?—That is what I have said. I have said that, in my opinion, and I hope in the opinion of the Commissioners, the Act of Parliament must be read in conjunction with the Report upon which it was founded, and that where distinct recommendations are made in the Report it is the duty of the Home Office to carry out those recommendations within the four corners of the Act.

10270. (*Chairman.*) You could not quite say that; I think no lawyer could say that that was his duty under the Statute. It may be an independent duty?—An independent duty, yes. If you look at the Statute as no doubt you have, the Statute begins by calling itself "An Act to amend the law relating to cruelty to animals," it therefore is a law entirely dealing with the question of pain. The whole Act is to place the regulations protecting animals from unjustifiable suffering in the hands of the Home Secretary and his officials. I mean, of course, that the Home Secretary personally, I presume, delegates it to his officials. Therefore I say that if the Act is read as the result of that Royal Commission, it must be taken that the duty is placed upon the Home Secretary to protect animals from unjustifiable suffering. Now, having as I consider established that, I refer you to Question 129, where Colonel Lockwood asks Mr. Byrne "What expert opinion guides the Secretary of State for the Home Department in deciding as to the painfulness of an operation"; and the answer is "The Secretary of State has not to decide whether an operation is painful or not." Therefore I say that the Home Secretary repudiates, in the words of Mr. Byrne, who, I presume, represents him, the duty which, in my opinion, was placed upon him under the Act.

10271. (*Sir Mackenzie Chalmers.*) Would you read the context there. The question was a question of statistics there?—(*After referring to the evidence.*) It is a perfectly fresh question where Colonel Lockwood begins; it has no relation whatever to the question before it.

(*Chairman.*) It appears to be so.

(*Sir Mackenzie Chalmers.*) But it was on the discussion of the new form of Returns—it arose out of that.

10272. (*Chairman.*) Will you continue, please?—Further down I find, at No. 163, that Sir William Collins asked Mr. Byrne—this is again on the question of pain. "Is that regarded as a painful procedure?" Sir William asked at Question No. 162 in regard to inoculation; and Mr. Byrne replied: "It is not a painful procedure, but it is considered a painful experiment." Then he is asked: "And is so classed?" and his answer is: "There is no classification of experiments in the last Report into painful and not painful; but it is regarded as undoubtedly painful by the Home Office." So that on one page the Home Office repudiate all responsibility about pain, and on the next page they say that they do regard a certain class of experiments as painful. Therefore it is quite clear that they do not altogether speak consistently upon this matter. Then the next question is: "Do I rightly understand that there was formerly a classification into painful and painless?" and the answer is: "Yes; if you will be so good as to look at the end of my memorandum relating to the Annual Return under the Act, you will find that at various stages attempts, mostly unsuccessful, were made to divide the experiments returned into those painful and those painless. That has now been given up, and the last Return does not even profess to do so." So that the Home Office have absolutely abandoned all attempt, so far as I can see, to take upon themselves the duty which I maintain is theirs. Perhaps now, while I am on Certificate A, I might say a word or two about Certificate A. I notice—and this is very interesting, I have made a great study of this—that before 1888, when Mr. Busk was the Inspector, in all the Annual Reports (and I have read them all very carefully through), there is no allusion of any kind to any conditions being attached to Certificate A. Down to 1888 I know Mr. Busk was Inspector, and there was no allusion anywhere in the Reports, as I have said, to any conditions being attached to Certificate A. And therefore it is a fair deduction that down to 1888, under Certificate A, any amount of torture might have been inflicted, because it relieves the operator altogether of the necessity of using anæsthetics in his operations.

10273. I do not quite follow why you say that?—Certificate A represents Sub-proviso 2: "Experiments may be performed without anæsthetics on such certificate being given as in this Act mentioned, that insensibility cannot be produced without necessarily frustrating the object of such experiments." Each year there is a Report and letterpress, and in the letterpress of late years there have been allusions to conditions which have been always attached to Certificate A before it was issued. Before 1888 there is no evidence from the letterpress and Reports, that any such condition was ever attached to it before it was issued; and therefore, I say, that down to 1888 there seems no doubt that under the administration of the Home Office permission was given to inflict any amount of torture upon animals, because experimenters were permitted to perform experiments without anæsthetics simply; all they had to do was to say that insensibility could not be produced without frustrating the object of the experiment; so that, if the experiment was to find out the result of pain, for instance, it obviously would not have been of any use if the animal did not feel the pain. I am only bringing this forward to show that under the present law any amount of torture not only may be, but I am afraid has been inflicted.

10274. (*Sir Mackenzie Chalmers.*) Now, let us go to since 1888?—I am going on to since 1888. In 1888 Mr. Erichsen became Inspector, and in his report for 1888 we find these words: "The 'inoculation condition' introduced last year, by which it was rendered imperative on the part of the experimenter to destroy the animal under anæsthetics, provided pain had been developed as the result of the conditions to which the inoculation gave rise, has been in all cases enforced." I regard that as a very proper and humane proviso that should be added to Certificate A, and it clearly apparently was added to Certificate A in 1887; in the Report of 1888 we find it. In the Report of 1889 we have an announcement to the same effect—namely, that as soon as pain is developed under inoculation the animal is to be destroyed. In 1890 I find a grave alteration was slipped into this Report. In this Report we find the "inoculation condition" is thus defined: "This condition renders it imperative on the operator to destroy the animal under an anæsthetic if severe pain has been induced, so soon as the result of the experiment has been obtained." That is a very different condition, you see. That lets in any amount of pain, provided the experimenter is of opinion that the result of his experiment has not been obtained; whereas, before that, there is nothing about the result of the experiment having been obtained. "If pain ensued, animal destroyed," was a further condition down to 1890. Therefore we see in 1890 this slips in, this permission of pain. In 1891 the words are: "The animal shall be killed if pain result." That appears to be a reversion again to the more humane conditions. And practically no allusion is made to the matter again under Dr. Poore's *régime*.

10275. (*Colonel Lockwood.*) Dr. Poore succeeded to Erichsen?—Dr. Poore succeeded to Erichsen in 1892. The last of Erichsen's Reports says: "The animal shall be killed if pain result." It seems that Erichsen reverted to his more humane condition before he retired, or died—whichever it was, I forget. Then

Hon. S Coleridge.

19 June 1907.

comes in Dr. Poore, and Dr. Poore never says a word about it. He maintains the mystery of silence as to the conditions under which Certificate A is issued, and in 1900 he retires. Then in 1901 Mr. Thane takes office; and this is what he says in his first Report: "In the event of pain ensuing, the animal to be killed 'as soon as the main result of the experiment has been attained.'" That obviously is, in my opinion, an inhumane condition. It lets in, so far as I can see, any amount of pain under Certificate A. The vivisector has only to form the opinion that the result of his experiment has not been obtained, and the animal can be subjected to as much pain as he thinks fit to inflict upon it. That is all I have to say on Charge 1. My next charge is that I charge the Home Office officials with having constituted themselves the injudicial defenders of the vivisectors from criticism by my Society in the past, and in their evidence tendered before this Commission. I wish to draw the attention of the Commission to Dr. Crile's book on "Surgical Shock."

10276. (*Sir Mackenzie Chalmers.*) There is one preliminary point I should like to ask you. On what do you base the distinction that you draw between the Home Office and the Home Secretary—between the officials and the Home Secretary?—I draw it on this ground. I suppose you are aware, like everybody else, that the answers prepared for the Home Secretary are prepared in the Office; I have common sense enough to know that, and I presume that the Office is therefore responsible for the answers given by the Home Secretary; that is all. I make no distinction, except that I do not attribute them to the Home Secretary himself.

10277. You do not surely regard the Home Secretary in answering to Parliament as a mere mouthpiece—a sort of telephone from the Office?—It is a matter of degree.

10278. (*Chairman.*) That is what you do regard him as, I understand?—The answers, I have not the slightest doubt, are prepared for him in the Office.

10279. They are prepared and drafted in the Office, no doubt, but the Home Secretary is responsible; and not only is he responsible, but, I think, not infrequently he suggests that they should be different?—It is not for me to draw a distinction; I am not inside the Home Office.

10280. (*Sir Mackenzie Chalmers.*) Constitutionally the Office does not exist; there is only the service of the Home Secretary, but practically, of course, everything has to be prepared for the Home Secretary, and he may or may not, according to his individuality, exercise his right?—That is too technical a point for me; that is for the Home Secretary and his officials to settle between them. I am quite aware that all the charges which I am now bringing have nothing to do with Sir Mackenzie Chalmers, because he was not there; and further, the Home Secretaries are gone too. There stand the permanent officials.

10281. (*Chairman.*) You put the blame on the permanent officials?—Certainly.

10282. (*Dr. Wilson.*) On the Department?—Yes, I regard the Department as my adversaries in this matter.

10283. (*Chairman.*) I think my expression was more accurate, because the Home Secretary is one of the Department; he is the head of it?—Yes.

10284. (*Sir Mackenzie Chalmers.*) I only wanted to know the reason for it?—That is it. I refer now to this book on "Surgical Shock," and somebody had better verify my quotations. Would you like it, my Lord?

(*Chairman.*) As this is relating to the Home Secretary, perhaps Sir Mackenzie had better have it before him, and I will listen.

(*Sir Mackenzie Chalmers.*) I have never seen it. (*The book was handed to Sir Mackenzie Chalmers.*)

(*Witness.*) If you look at Experiment CXXXIII—I do not know the exact page—you will see the description.

10285. Let us see who Mr. Crile is?—He is an American who came over here and had a licence given him from the Home Office to perform certain experiments, and he did them in Sir Victor Horsley's laboratory. The first 16 were done in England, and I will not allude to the others, except that just in passing I must allude to two which were not done in England; and I will tell you why. I want to show that the personal taste of Dr. Crile does not prevent him from torturing animals. In experiment CXXXIII. we find these words (I am just going beyond England for the moment); he says "Experiment lasted two and a-half hours. Flame was applied to the dog's paw, and we are told, in the control experiments, as well as in this, the dog was not under full anæsthesia. In the former the animal struggled on application of the flame.'"

10286. That was an American experiment?—I think so; it was not done in England, anyhow.

10287. And he put as the anæsthetics chloroform and ether?—I do not care what they were; they were not full.

10288. (*Chairman.*) You only read that experiment to show that Dr. Crile is capable of performing what you consider a cruel operation?—Yes; and there is one other experiment, No. CXXVII., just before that one, "The animal did not take the anæsthetic well, and a part of the experiment was made under incomplete anæsthesia, the anus and rectum of this dog were then 'dilated.'" These quotations I merely read to show that the personal taste of Dr. Crile does not prevent him from inflicting torment, in my opinion. Now I come to what was done in Sir Victor Horsley's laboratory. I will go by steps. On page 17, Dr. Crile states "In the first 16 experiments which were carried out in the University College, London," so and so.

10289. You now, I understand, are going to read descriptions given by Dr. Crile of operations carried out by himself in Sir Victor Horsley's laboratory?—Yes, that is how he describes them himself in his own book. On page 23, Experiment V, performed on the 8th of May, 1895, is thus described:—"Healthy male foxterrier, three years' old. Central pressure in femoral. Preliminary section of the inferior branches of the right stellate ganglion, by dissection between the scapula and the spinal column, resecting two ribs. Under incomplete anæsthesia, crushing of foot caused a very sharp rise, followed by an equally sharp decline of pressure. This was repeated several times." Here we have Dr. Crile's own description of crushing the animal's foot under what he himself calls "incomplete anæsthesia." That was done by Dr. Crile under a simple licence, which provided that the animal must be under complete anæsthesia during the whole experiment, and be killed before it recovers consciousness. I want to point out that in Dr. Poore's Report these 16 experiments were not described as painful, and therefore we must assume that the Home Office regarded them as painless, or chronicled them as painless. Over Dr. Poore's signature are these words:—"In experiments performed under licence alone, the animal suffers no pain, because complete anæsthesia is maintained from before the commencement of the experiment until the animal is killed." Therefore the Home Office Inspector, in his own Report, states for the public delectation that animals when vivisected under licence alone are always under complete anæsthesia.

10290. Are the words "incomplete anæsthesia" in the account which Dr. Crile gives of his own experiment, the account which has been given in by him to the Home Office?—Whether it was sent in to the Home Office or not I do not know.

10291. It makes a difference, when you are bringing a charge against the Home Office?—I laid the book before the Home Office afterwards.

10292. It makes a difference whether Dr. Poore was informed that it was done under "incomplete anæsthesia." We are informed in this book by Dr. Crile that it was so; but I presume that Dr. Poore's Report would be founded upon the Report sent in to him by Dr. Crile?—We have it in evidence—I have read it—I cannot at the moment refer to it, but I am sure I can find it—that it is an instruction to all vivisectors to send to the Home Office any pamphlets or publications detailing and accounting for the experiments which they are licensed to perform; and, therefore, I assume that if Dr. Crile did his duty and fulfilled the conditions upon which his licence was given to him, he must have sent that book to the Home Office.

10293. We do not know that it was printed at the time?—Anyhow, I sent it to the Home Office later on.

10294. I mean, that we do not know whether at the time it was before Dr. Poore?—That is a matter for the Home Office to answer. I do not know; I cannot tell.

10295. (*Sir Mackenzie Chalmers.*) It is an American

book, and curiously enough it does not seem to have any date. It seems to have been an Essay which was awarded the Cartwright prize for 1897?—Yes.

10296. That is two years afterwards?—Yes.

10297. (*Chairman.*) That book itself could not have been submitted to the Home Office at the time. However, when we examine the Home Office Reports, we shall see what there was?—I am comng on to that in a moment. I then drew the attention of the Home Office to these experiments which were done in Sir Victor Horsley's laboratory.

10298. When you say then, will you tell us when that was?—I wrote to the Home Office on the 18th May, 1899.

10299. (*Sir Mackenzie Chalmers.*) That is four years afterwards?—It may have been.

10300. From 1895 to 1899?—Yes, that is right. I do not have these books sent to me, you see. Somebody at last sends me a thing, and I at once act when I see it. Then the Home Office asked me to lend them the book—that happened next; so I lent them the book; and their answer was that on receiving my letter, "The Secretary of State caused investigations to be made into these experiments, and the information he has received from competent persons, who either witnessed most of the experiments, or have read the account of them, is to the effect that in no instance had the animals experimented upon been subject to pain."

10301. (*Chairman.*) You told us that you wrote to the Home Office calling attention to this. Was your letter calling attention to Dr. Crile's book generally, or was it calling attention to the statement that this particular dog was under incomplete anæsthesia?—I drew their attention to the experiments which Dr. Crile had done in Sir Victor Horsley's laboratory, and I drew their attention to their own statement in their corresponding statement for the same year alluding to complete anæsthesia, and pointed out the discrepancy. I say that these investigations which the Home Office made can, so far as I can see, have had no other nature than inquiry from the persons responsible, and, therefore, on their defence. It is quite incredible to suppose that inquiries as to whether a dog was put to torture in a particular laboratory of the persons who are responsible for what goes on in that laboratory, will result in anything but a distinct assurance that no pain was inflicted. Human nature being what it is, you cannot expect anything else. I say that those investigations can have had no other nature than inquiry from the person whose conduct is impugned—whether he did it or not; and I say that to make such an inquiry as that, and then write back to me and give me the result of those inquiries as settling the matter, is, in my opinion, simply defending the vivisectors from criticism, and nothing else. They went on and said: "The use of the term incomplete anæsthesia has probably given rise to the misunderstanding. With regard to this," the Home Secretary says, through the hand of Mr. Cunynghame, "the Secretary of State is advised that there are various degrees of anæsthesia. In 'complete anæsthesia' the narcosis is very profound, and the 'reflex movements,' that is the involuntary movements in response to an external stimulus, are suppressed. One of the last of these reflex movements to disappear is the blinking of the eyelids when the surface of the eyeball is touched, thence called the 'corneal' or 'conjunctival reflex.' But short of this is the condition termed by Dr. Crile 'incomplete anæsthesia,' in which the creature is quite insensible to pain, although the corneal and other reflexes can still be obtained." Now "it is quite usual for even severe operations to be performed on man in this state of 'incomplete anæsthesia.'" That is the statement of the Home Office, presumably advised by—well, I do not know whether it was Dr. Poore, I suppose it was; they do not tell me by whom they were advised, and of course I cannot tell.

10302. On what ground do you assume that it was Dr. Poore?—I would assume that Dr. Poore is their adviser, and in the next charge I shall proceed to show that Dr. Poore was a man of very strong bias, wholly incapable, unless through very serious and strenuous effort, of forming an unprejudiced opinion on such a matter as this.

10303. I am afraid that we find a great many of those people on both sides?—No doubt, my Lord, but not, I should hope, in an official position. I am not in an official position. I admit all sorts of prejudices.

10304. I would not go so far as to say wholly incapable of forming an opinion; you might say considerably prejudiced?—Well, considerably prejudiced—biassed I will say. Having received that letter, of course I had to consider what was my position. Here was the Home Office ready to tell us, on the advice of some nameless adviser who no doubt took the responsibility upon himself, that it was "quite usual for severe operations to be performed on man in this state of incomplete anæsthesia," that is, before the corneal reflexes were abolished. Well, I thought that I would test that, and I took the liberty of writing a letter to a certain number of the most important and eminent surgeons of the day, informing them that I had been told on very high authority that "surgeons now frequently perform severe operations on man under incomplete anæthesia, that is, before the corneal reflexes are abolished." Those are the words of my letter to the surgeons. I put it perfectly fairly, exactly as the Home Office put it to me. The replies were very remarkable.

(*After some deliberation.*)

10305. (*Chairman.*) As some of the Commissioners wish the letters to be read, will you please read them?—In the first place, I ought to read my letter to the surgeons. It was as follows: "Dear Sir,—A statement has recently been made to me in writing by a very respectable authority that surgeons now frequently perform severe operations on man under incomplete anæsthesia, that is, before the corneal reflexes are abolished. I know of no way of answering this statement but by obtaining definite information from persons like yourself, whose large experience renders their authority on such a matter conclusive. I should, therefore, really be very much obliged to you if you would be so good as to enable me clearly to assert on your authority that, provided complete anæsthesia can be given with safety to a patient, and provided the nature of the operation itself does not render it dangerous to the patient's life, complete anæsthesia is always administered in *severe* surgical operations. You may possibly be aware that I am one of those who on humanitarian grounds oppose the vivisection of animals as practised in this country, but I hesitate to believe that patients in hospitals are treated with inhumanity. I hope you will pardon this intrusion upon you, which arises from the prominent position you occupy in your profession.—Believe me to remain very faithfully yours. (Signed) Stephen Coleridge." I will now read some of the answers that I received. I ought to say that I am not going to pick out those which favoured me at all. I will give you the whole. There were only two of an adverse view who associated themselves with the Home Office view, and those two replies were from licensed vivisectors who were unconnected with any hospital. The first is from Dr. Bond, F.R.C.S., senior surgeon and lecturer at the Westminster Hospital. He says: "I think you have been very much misinformed, and it would be very interesting to me to know the very high authority on which your information is based. Hundreds of operations are performed yearly at Westminster Hospital, and never to my knowledge is the operation commenced under incomplete anæsthesia." I informed Dr. Bond afterwards that the information reached me in a letter from the Home Office. Dr. Edmund Owen, F.R.C.S., Member of the Council of the Royal College of Surgeons, senior surgeon at St. Mary's Hospital, and senior surgeon at the Hospital for Children in Great Ormond Street, says: "Certainly, in my experience complete anæsthesia is *always* secured in severe surgical operations."

10306. (*Mr. Tomkinson.*) Are those the whole of the letters?—No.

10307. Did the first letter not refer to the question of the eye?—No; they answered my letter. I defined incomplete anæsthesia in my letter, "that is, before the corneal reflexes are abolished."

10308. There is no allusion to that in the reply?—No, they have taken my definition and used the words "incomplete anæsthesia." Dr. Timothy Holmes, F.R.C.S., Vice-President of the Royal College of Surgeons, and treasurer and consulting surgeon at St. George's Hospital, says: "I differ entirely from your informant who says that it is quite usual for even severe operations to be performed on man in a state of incomplete anæsthesia. . . . . Never did I hear of performing serious operations with incomplete anæsthesia, and if you know anything of operative practice you would know that it would be as embarrassing to

Hon. S. Coleridge.
19 June 1907.

the operator as painful to the patient. . . . . If you accept this statement as true you are quite at liberty to make use of it to your informant; or if your informant will, in his own name, repeat his statement in any respectable paper, I will in my own name repeat the above." Dr. Jonathan Hutchinson, F.R.C.S., late President of the Royal College of Surgeons, consulting surgeon at the London Hospital, and consulting surgeon at the Royal London Opthalmic Hospital, says: "I have not the least doubt that when complete anæsthesia is considered safe, and on the patient's part desirable, it is always secured." Dr. G. May, consulting surgeon at the Royal Berkshire Hospital, says: "I have been attached to the Royal Berks Hospital about forty-five years, and have never known a case of operation where anæsthesia was not complete. This is done not only to spare pain, but because it is thought to be less dangerous." Dr. T. J. Walker, M.R.C.S., who has been for a very long time senior surgeon at the Peterborough Infirmary, says: "Taking my authority for what it is worth, you may assert on my authority that, provided complete anæsthesia can be given with safety to a patient, and provided the nature of the operation itself does not render it dangerous to the patient's life, complete anæsthesia is always administered in severe surgical operations." And this last one is most interesting. Dr. Thomas Bryant, F.R.C.S., Surgeon Extraordinary to Her Majesty the Queen, consulting surgeon at Guy's Hospital, and late examining surgeon at the University of Cambridge, says: "I have received your circular, and read it with surprise, as you clearly have been hoaxed." I replied to that letter that the august quarter from which the information emanated seemed to me to preclude such an hypothesis. I had two replies from two licensed vivisectors, one from Professor Horsley, to the effect that he was out of the country, and the other from Professor Schäfer, that the Home Secretary's advisers are quite correct, and that incomplete anæsthesia "is consistent with complete unconsciousness." As I say, Sir Victor Horsley did not answer, but Professor Schäfer at that time was not, and, so far as I know, still is not in any way connected with an hospital.

10309. You said that there were two who differed?—I thought that there was. I see one did not answer; it is my mistake.

10310. (*Dr. Gaskell.*) Did you say that Professor Schäfer said that the Home Office statement was correct?—Yes, in reply to that letter, although I gave no indication that it was the Home Office at all; he deduced, no doubt, that it was the Home Office.

10311. You had not told him that it was the Home Office?—No.

10312. (*Chairman.*) Are those the whole of the letters?—Yes, except one which I left out.

10313. I did not mean were they all the letters, but have you read the whole of each letter?—I believe so; but I can get the originals. I am not sure. I did not read one from Dr. Herbert Snow, surgeon at the Cancer Hospital, who says, "You must have been misinformed so far as my knowledge goes upon the point at issue," as he has been a witness here.

10314. (*Colonel Lockwood.*) Those are not *précis* of the letters; they are the entire letters?—So far as I know. I placed all the replies before the Home Secretary in a letter to the Home Office, and I received no further reply from them. I remain of the opinion that those collected opinions of those great men outweigh the anonymous advice received by the Home Office. I will not say that Dr. Poore, but whoever it was, I think he misinformed them; and at any rate, I maintain that with those letters before them the Home Office ought to have recognised that they were of great weight. But they never answered me in any way, and, so far as I know, Dr. Crile was never censured.

10315. (*Sir Mackenzie Chalmers.*) Do you know when Dr. Crile returned to America?—No. I will not be quite certain, but I think that even subsequently to those experiments, and subsequently to the receipt of all those letters from me by the Home Office, Sir Victor Horsley, in whose laboratory the crushing of that dog's foot under incomplete anæsthesia took place, still received permission from the Home Office to vivisect where he liked, and not in any registered place.

10316. (*Chairman.*) Was Dr. Crile at that time on a visit to England?—So far as I know.

10317. He never took up his abode here to practice?—No, he went back to America, and he has issued another book since in America. Now the next point I will take up on this same charge is in relation to a question asked by Mr. Weir of the Home Secretary.

10318. (*Colonel Lockwood.*) You mean the present Member for Ross and Cromartie?—Yes, I think he is. "I beg to ask the Secretary for State for the Home Department if he will state the number of persons in England, Scotland, Ireland and Wales respectively, licensed to practice vivisection, and how many of them hold certificates to dispense with anæsthetics." Sir Matthew White Ridley replied, "The number of persons licensed at the present time in England is 145; in Scotland, 52; in Wales, one. The number holding the certificate dispensing with anæsthetics is, in England, 86; in Scotland, 30; in Wales, none. The only figures in my possession as regards Ireland are those for 1895. In that year the number of licensees was six, of whom one held a certificate dispensing with anæsthetics." Now comes the point; this is a voluntary statement on the top of the answer: "In giving the honourable Member these figures, I may remind him that the certificate in question is never given for operations involving serious pain, but only for such operations as inoculations or hypodermic injections." That answer, I am going to assume, was prepared for Sir Matthew White Ridley in the Home Office, and I say that that answer might be intended for the public to believe, and undoubtedly had the effect, and would have the effect, of persuading the public that in all cases of certificates exempting the licensee from the use of anæsthetics, such certificates are only issued for such operations as inoculations or hypodermic injections, when all the while there is Certificate B being issued; and I say that such an answer as that is not a fair answer. That statement of Sir Matthew White Ridley's, I maintain, is quite unfair. It really only refers to Certificate A, and Certificate A plus E, and omits all reference to experiments under Certificate B. But the question does not omit reference to Certificate B. The question is: "How many of them hold certificates to dispense with anæsthetics." I say Certificate B dispenses with anæsthetics.

10319. (*Sir Mackenzie Chalmers.*) No?—Certainly Certificate B dispenses with anæthetics immediately after the initial operation is over; and under Certificate B the moment the initial operation is over (the opening of the animal and fixing the electrodes to the ends of the nerves and tubes down the veins), there is nothing in the law and nothing in the certificate to prevent the animal remaining disembowelled on the table for hours while observations are made upon its blood pressure and various things, while stimulations of electricity are passing through it. Under the present law there is nothing to prevent it, and I say that that is what horrifies the public; and that is carefully hidden in this answer.

10320. (*Chairman.*) I have not been able to follow you, not having the question and answer before me, but do you say that looking at the question the answer is distinctly a misstatement, or is it something which a person who did not know the Act might misapprehend?—That is it.

10321. That is a very different thing, of course. A person who asks a question in the House of Commons is generally supposed to know with reference to what he is asking it, and he can understand the answer?—Perhaps I have made a mistake. The question, in my opinion, involves Certificate B; the question certainly involves "How many of them hold certificates to dispense with anæsthetics." Certificate B is a certificate dispensing with anæsthetics.

10322. (*Sir William Church.*) No?—I beg your pardon; it is so worked in practice, and it is so chronicled every year in the report under certificates dispensing with anæsthetics.

10323. (*Sir Mackenzie Chalmers.*) The animal is allowed to recover. May I just call your attention to the words of Certificate B; it is on page 7. Have you got a copy?—I have not got the Certificate here at the moment, but I know it by heart.

10324. It authorises a person "To perform on living animals certain experiments described below, such animals being, during the whole of the initial operation of such experiments under the influence of some anæsthetic of sufficient power to prevent their feeling pain"?—Yes, during the whole of the initial operation of such experiment, the experiment consisting of first opening the dog, and then chronicling what may

happen to the blood pressure and other things, during hours, perhaps, of subsequent experiments.

10325. (*Dr. Gaskell.*) No; that is all the initial experiment?—No, I beg your pardon.

10326. (*Chairman.*) I do not think this comes to much, really, as a charge against the Home Office; because it is admitted that the answer to the question is one which, technically to a person who understood it, is a correct answer, but one which might lead a person who was not familiar with the Act to misapprehension. It is really putting too much upon the Home Secretary to suppose that he is to make his answer with reference to a person who does not study the Act?—The question is a very clear one. The question asked by Mr. Weir was how many of these gentlemen hold certificates to dispense with anæsthetics, and the Home Secretary gives only those who have Certificate A. He suppresses apparently those who have Certificate B, because he adds the rider: "In giving the honourable member these figures I may remind him that the certicate in question"—that must mean only Certificate A—"is never given for operations involving serious pain, but only for such operations as inoculations or hypodermic injections." I say that that is a disingenuous answer.

10327. To me, hearing you read it, it seems rather a forced construction to put upon it. I think that the unbiassed person, whom we have not yet been able to find, would say that it was rather a forced construction to put upon it?—The question involves all certificates dispensing with anæsthetics.

10328. (*Sir William Collins.*) Are the words "Certificate A" mentioned in the question?—No; the words are: "Certificates to dispense with anæsthetics." I say that Certificate B dispenses with anæsthetics, and therefore it should have been included in the answer.

19329. Did you say that you were going to refer to some return indicating that Certificate B is classed with those certificates dispensing with anæsthetics?—Certainly. There is in the last Report: "Certificates held by each licensee dispensing with the obligation to kill the animal before recovering from anæsthesia"; that is coupled with Certificate E E, and is called "Permitting experiments on dogs, cats, etc.," "Dispensing with the obligation to kill the animal before recovering from the anæsthesia."

10330. (*Chairman.*) It is not expressed there that Certificate B is to dispense with anæsthesia. It really seems to me a small point, I confess. You must have some more important things to come to?—Very well, my Lord; I pass from that then. I next come to the case of the "Chemist and Druggist," of December the 14th, 1901, in which there is an account of an address delivered by Professor Sherrington to a number of chemists and druggists, when the professor is reported to have called upon Dr. Grünbaum to demonstrate the action of the snake antitoxin upon some rabbits. The Report then goes on: "The first was inoculated with cobra venom, the second with antivenom, and the third with the cobra venom and antivenom. The first died in about 30 minutes, completely paralysed by the venom of the snake. The second, although it had also been subsequently inoculated with cobra venom, lived, and was full of life. The third, which had subsequently been inoculated with the anti-venom, also lived, and exhibited a considerable amount of liveliness."

10331. (*Colonel Lockwood.*) Where was this?—I think in Liverpool.

10332. (*Sir Mackenzie Chalmers.*) What was the date of it?—It was published in the "Chemist and Druggist" of the 14th December, 1901. The points that I raise here on this are these:—First of all, I say that Dr. Grünbaum here broke the law. He broke it first, according to this account, by demonstrating at a lecture without Certificate C; that is the first breach of the law that he made—he had no Certificate C, and he was called upon by Professor Sherrington to demonstrate the action of the snake antitoxin upon some rabbits, and he proceeded, according to the account, to do so. Secondly, he appears to me to have broken the law by performing an experiment merely to demonstrate what was already known with this Certificate A; he has Certificate A, but it was to demonstrate something that was already known.

10333. (*Chairman.*) It would not be against the law on his part if it was certified to be a proper case for experiment, would it?—Yes.

10334. With Certificate A?—Yes.

10335. Even although it was passed by the President of the College of Physicians or Surgeons?—Yes, Certificate A does not permit you to get outside the Act. If you are to demonstrate something that is already known you cannot do it. Section 3, Sub-section (1) of the Act provides that the experiments must be performed "With a view to the advancement by new discovery of physiological knowledge or knowledge which will be useful for saving or prolonging life or alleviating suffering."

10336-7. (*Sir Mackenzie Chalmers.*) Generally?—No, it is a question of commas; there are no commas at all. (*After a pause.*) I say "A new discovery." Then there ought to be a comma: "Of physiological knowledge or knowledge which will be useful to them for saving or prolonging life." It must all be a new discovery.

10338. (*Dr. Gaskell.*) No?—Certainly.

10339. (*Chairman.*) A new discovery of knowledge, do you mean?—Yes, it must either be a new discovery of physiological knowledge, or other kind of knowledge which will be useful to them for saving life, or alleviating suffering. It must be for a new discovery of one of those two forms of knowledge.

10340. Surely the terms are that the experiment must be performed "With a view to the advancement" (leaving out some words for the moment) "of knowledge"?—No; it is the new discovery that is the point of the whole section, surely.

10341. The advancement by a new discovery of physiological knowledge?—But the new discovery is the whole point, I think.

10342. Yes, but the new discovery is "The advancement of physiological knowledge, or of knowledge"?—Yes, I think you must take it so; because if you look over the page there is a certificate exempting the holder of it from this particular.

10343. But what I rather meant was. Supposing that a description of what is proposed to be done is sent in, and a licence is asked for, it would not be necessary in that case, if he was licensed generally; he could do the experiment under the general licence, if he had it under Section 1?—No, not without anæsthetics.

10344. No, with anæsthetics?—There was not any anæsthetic in this case; there is no suggestion of it.

10345. But Sub-section (1) is the sub-section which deals with the performance of an experiment which must be done under anæsthetics?—No.

10346. Then the other Sub-sections create an exception?—No, you begin at Section 3, Sub-section (1); you have not got to the question of anæsthetics at all then. It is the beginning of the Act; it begins at the very beginning; it says that you must not do these things except for the purpose of new discovery, that is by Sub-section (1)—nothing else. You must not go on doing the same thing over and over again. That is what it is for. It has nothing to do with anæsthetics at all. The question of anæsthetics comes over the page.

10347. (*Sir William Collins.*) Is your point that, apart from certificates altogether, this was a case in which either a licence could not have been granted for such a purpose, or if a licence had been granted he was transgressing it?—Yes; if a licence was ever held at the time I am prepared to show that Dr. Grünbaum broke the law in what he did.

10348. (*Chairman.*) Sub-section (4) is material, is it not, "Experiments may be performed not directly to the advancement by new discovery of physiological knowledge, or of knowledge which will be useful for saving or prolonging life or alleviating suffering, but for the purpose of testing a particular former discovery"?—Yes, that is so. He had not got that certificate either.

10349. (*Sir William Collins.*) Is that Certificate D?—Yes; he had not got that either. Therefore he was absolutely outside the law, and had no business to do it. He first broke the law, I say, by demonstrating at a lecture without Certificate C. This was really a lecture where there were a large number of persons present—chemists collected there to hear the lecture, and he was invited by Professor Sherrington to do this particular thing which he had no right whatever to do, and he performed the experiment merely to

Hon. S. Coleridge.

19 June 1907.

demonstrate what was already known with Certificate A; therefore he violated the section which I have just read, Section 3, Sub-section (1). And, further, I contend that it is highly probable that by performing an experiment before the general public he violated Section 6; because I see no reason why a collection of chemists should be regarded as anything else than the general public. Section 6 says: "Any exhibition to the general public, whether admitted on payment of money or gratuitously, of experiments on living animals calculated to give pain shall be illegal." I do not see why a collection of chemists who go to a place should be regarded as anything else but the public. Therefore I maintain that under several headings Professor Grunbaum was entirely outside the Act of Parliament. I drew the attention of the Home Office to these various performances of Dr. Grunbaum, and they replied that it would have attention—that is the first thing. I drew their attention to it on the 17th December, 1901; I waited till the 20th February, 1902, and had no reply. I asked them then if they would kindly give the matter their attention, and then they wrote back to say, "I am directed by the Secretary of State to inform you that he has caused careful inquiry to be made into the matter. The experiments were performed under a Certificate A, the authorities who granted the certificate being, no doubt, of opinion that such experiments tended to the advancement, by new discovery, of physiological knowledge, or of knowledge which would be useful for saving or prolonging life or alleviating suffering."

10350. (*Colonel Lockwood.*) That is Sub-section 4?—Yes, that is it, Sub-section 4 of the proviso. That is practically indicating that the authorities who granted the certificate granted him Certificate D. But he had not got that.

10351. (*Chairman.*) Would you read the words again. That is the same Sub-section (1), is it not?—No, I am on Sub-section (4), which would take him out of Sub-section (1).

10352. What was it you were reading?—I was reading from the letter of the Home Office to me.

10353. What does the letter of the Home Office say?—The letter of the Home Office says: "The experiments were performed under a Certificate A," not D, "the authorities who granted the certificate being, no doubt, of opinion that such experiments tended 'to the advancement, by new discovery, of physiological knowledge, or of knowledge which would be useful for saving or prolonging life or alleviating suffering.'"

10354. Those are the words of Sub-section (1)?—Sub-section 4.

10355. They are the exact words that I have in my hand of Sub-section (1)?—Your Lordship is quite right—Sub-section (1). "Dr. Grünbaum states that the report of the proceedings is somewhat misleading, in that the experiments were not performed until after Professor Sherrington had finished his address, and that they were not in illustration of a lecture. He has, however, conveyed an assurance to the Secretary of State that such experiments in similar circumstances will not be repeated." In my opinion, and I think in the opinion of any fair person, it is quite clear that the Home Office asked Dr. Grünbaum what his account of this was, and Dr. Grünbaum said that the newspaper was all wrong, that this perfectly impartial person I suppose had called upon Professor Grünbaum to demonstrate the action of snake poison, and he demonstrated it to nobody at all—they had all gone apparently. But it is quite clear that the reporter was there.

10356. (*Dr. Gaskell.*) May I ask, were these experiments done in a physiological laboratory?—No doubt it was in a registered place; I am not saying that it was not. I do not suggest that it was not.

10357. Was Dr. Grünbaum working at snake poison at the time?—I do not know; I suppose he was. That I know nothing about.

10358. After the lecture was over he went on with his experiment, and some of the chemists came and looked on?—You are putting that to me?

10359. That is the suggestion of Dr. Grünbaum, I mean?—No, I do not think that is quite so. "Dr. Grünbaum states that the report of the proceedings is somewhat misleading, in that the experiments were not performed until after Professor Sherrington had finished his address." The "Chemist and Druggist" does not say that. The "Chemist and Druggist" says that when Professor Sherrington had finished his address he called upon Dr. Grünbaum. Dr. Grünbaum states "that they were not in illustration of a lecture."

10360. That is all I meant to convey?—Dr. Grünbaum considered that he was going on with work which he was doing before, and the chemists and druggists saw it.

10361. (*Sir John McFadyean.*) Have we any information as to the precise object of Professor Sherrington's address?—It is headed "A Physiological Experiment in Relation to Pharmacology."

10362. (*Chairman.*) That would not be on snake remedies?—I am not a scientific man, my Lord. Would you like to look at at?

10363. (*Sir John McFadyean.*) Therefore, if Professor Sherrington was lecturing on an entirely different subject, Dr. Grünbaum's demonstration could hardly be part of the lecture. Would you mind letting me look at it?—Certainly. (*Handing a newspaper to Sir John McFadyean.*) You see the newspaper reporter asserts practically that Dr. Grünbaum demonstrated this to the chemists and druggists assembled, and to himself too. He describes what he saw. It took 30 minutes; the wretched animal died in 30 minutes completely paralysed by the venom of the snake. That is his description of what he saw. I maintain that he was one of the public, and Dr. Grünbaum broke Section 6 of the Act.

10364. (*Sir Mackenzie Chalmers.*) Just on that point do you say that if one single member of the public is present at an experiment, that breaks the Act?—Yes, one genuine member of the public.

10365. For instance, if you or I went in?—Certainly I should consider myself one of the public.

10366. If any one of the public went in?—I have been invited to go into laboratories, but I do not propose to assist physiologists to break Section 6.

10367. That is your view of the law?—Certainly. I do not set up to be a very great lawyer, but Section 6 seems to me to be quite clear. If I may go in, I presume that anybody may go in—a cabman off the next rank, or anybody.

10368. (*Chairman.*) You have given us the complaint made, and the answer of the Home Office?—Yes.

10369. And nothing more happened?—No. I think Dr. Grünbaum got his licence again.

10370. (*Sir John McFadyean.*) Professor Sherrington does appear to have referred to snake poison in his lecture?—Dr. Grünbaum still has a licence. That is the complaint I have to make upon that. I will just rehearse it again. I maintain that he broke the law by demonstrating at a lecture without Certificate C, by performing an experiment merely to demonstrate what was already known by Certificate A, and by performing an experiment before the general public in contravention of Section 6. I maintain that those breaches of the law took place, and that the Home Office associated itself with his defence. Now, the next case I want to draw attention to is that of Messrs. Dixon and Brodie, in the "Journal of Physiology," volume xxix., No. 2.

10371. (*Sir Mackenzie Chalmers.*) Will you give us the date?—The "Journal of Physiology" is very badly dated, but I give the page. It is page 144. I think at the very beginning they give you the date; but those volumes are a collection of papers. On page 144 these two vivisectors make the following statement: "In studying these reflexes we have found it of the utmost importance to avoid the use of chloroform or ether as the anæsthetic. The experiments must, therefore, either be performed upon unanæsthetised animals, upon animals anæsthetised with morphia, or upon decerebrate animals. Our experiments were usually conducted under one of the two latter conditions, but in a few instances were repeated upon animals lightly anæsthetised with chloroform." We say that this kind of light anæsthetisation—when we are told that to be of any use, if the animals have not morphia or are not decerebrated, they must be unanæsthetised—awakes in us the profoundest distrust.

10372. Could you let me look at that paper?—Certainly (*handing the volume to Sir Mackenzie Chalmers*).

10373. (*Chairman.*) Was complaint made of it to the

Home Office?—Yes, I made complaint. This was defended by the Home Office, so far as I can make out, on the bare assurance of the authors of the paper; they speak of "The authors of the paper."

10374. (*Sir Mackenzie Chalmers.*) The paper itself does not refer to any specific operation or any specific operation on any specific animal?—I daresay it does not. I am dealing with the particular passage which I have quoted.

10375. (*Chairman.*) On some animals lightly anæsthetised?—"Upon animals lightly anæsthetised with chloroform." It was a long time before I got an answer to that complaint either. I wrote on the 30th of March, 1903, to the Home Office, and I did not get a reply till the 9th of July; they then answered me, and this is what they say. "Adverting to your previous letter, I am to point out that on page 102 of the volume referred to it is explicitly stated that, except in the case of animals killed by pithing, all were anæsthetised. On page 144 it is said that in a few instances the animals were lightly anæsthetised with chloroform. The authors of the paper explain what is denoted by the term 'light anæsthesia,' viz.: that the animals were anæsthetic"—that is the word; "*i.e.*, they could not feel pain, but that the anæsthesia was not carried so far as to abolish all reflexes. The inquiry which has been made confirms that none of the experiments described in this paper were performed on unanæsthetised animals"—I did not say that they were—"Under these circumstances there is no reason for thinking that the provisions of the Act, viz., that the animals must, during the whole of the experiment, be under the influence of some anæsthetic of sufficient power to prevent the animal feeling pain, was not complied with." So that the Home Office defends an experiment upon an animal of which the authors say that these particular experiments must be performed either upon unanæsthetised animals, or upon animals anæsthetised with morphia, or upon decerebrate animals, and they allude to experiments not under the last two conditions, the experimenters themselves saying that they must be unanæsthetised to be of value. They cover up the unanæsthetisation, in my opinion, by speaking of them as "lightly anæsthetised with chloroform"; because if they were anæsthetised properly with chloroform, according to their own description, the experiments would be valueless.

10376. We have had doctors giving their account of what they understand by the expressions "lightly anæsthetised" and "completely anæsthetised"; but it is a medical question, is it not? Supposing that the Home Secretary, who is not himself a skilled physiologist, is informed that "lightly anæsthetised" is an expression which is consistent with the animal not feeling pain, would not the Act then have been complied with?—That entirely depends.

10377. I mean, as regards the charge against the Home Office. I am not considering whether Messrs. Dixon and Brodie's experiments were lawful?—The answer that I should make to that question is, that it depends upon where the Home Secretary goes for his information. If he goes to the Association for the Advancement of Medicine by Research, which is composed of vivisectors, I should say that the information is not sufficient.

10378. Then would you go so far as to say that the Home Secretary must go to somebody who holds anti-vivisection opinions?—Certainly not. Let him go to Mr. Sewell—to some person who is always operating on dogs for their benefit; let him go to some well-known thoroughly-skilled dog doctor.

10379. You exclude the whole medical profession from that—the ordinary M.D.'s?—So far as I know the ordinary M.D.'s, they are not vivisectors, therefore their opinion as to what is proper anæsthetising for a dog would not have the same weight with me, and ought not, I presume, to have the same weight with the Home Secretary, as the expression of such a man as Mr. Sewell.

10380. Assuming that the Home Secretary went to a person who was a skilled physiologist, and he gave him that explanation, you say that he ought to appeal to a veterinary surgeon?—I think so. I think he should go to an impartial person, and I do not think, looking at it from the point of view of the Home Office, that a licensed vivisector is an impartial person on this question. And on this occasion you must remember to whom the appeal was made—to the authors of the paper. What answer could the Home Secretary expect to get from the authors of the paper, whatever they said in the paper, except that the animal did not feel anything? He never could have expected the authors of the paper to write back and say "we tortured these animals."

10381. Supposing that the Home Secretary had advisers who advised him that "light anæsthesia" is an expression which may cover, in the minds of medical men, absence from pain—I do not know how it is—but supposing he had been so advised, would you say that he was to blame for saying that he found that the law had not been broken?—My answer would be this: that supposing in the former case he had consulted Sir Victor Horsley and Professor Schäfer, he would have got the answer which I have read, that of course, the experiment was completely painless. But if he had consulted Dr. Boyd, if he had consulted Mr. Jonathan Hutchinson, if he had consulted the great surgeons whom I consulted, he would have got the answer that I did, that such a thing was not anæsthetic, and that the corneal reflexes should be abolished before the operation is begun. My complaint against the Home Office is that they go to the vivisectors themselves for advice as to what is painful, and that they have done so always. I shall come on by and bye to the provisions of my Bill, of course. I now come to another case. In Volume XXVI. of the "Journal of Physiology." On page xxxviii. of the Proceedings of the Physiological Society of March 16th, 1901, you will find that Mr. J. Herbert Parsons, in a report of his experiments on dilatation of the pupil from cerebral stimulation, makes the following statement:—"The following are some of the results obtained: (1) Dilatation of the pupil, like other effects of cortical stimulation, is best obtained with slight anæsthesia."

10382. (*Sir Mackenzie Chalmers.*) Is that a general abstract statement, or is he describing certain specific experiments which he made?—At this distance of time I cannot say; you have it there.

10383. (*Chairman.*) What is your complaint about it; did you complain to the Home Office?—Yes, I complained that they allow this slight anæsthesia, and the Home Secretary referred me to page 368 of that volume, where I should find it stated that "the animals in question were completely anæsthetised and insensible to pain throughout the experiments." That, I presume, is a general statement with which vivisectors very frequently now begin a statement of all their experiments, and then when you come to detail you find these words, "slightly anæsthetised." They cannot both be true. Therefore all that the Home Office did when I pointed out that this man himself said that he did these experiments under slight anæsthesia was to point out that he himself, the same man, says somewhere else that the animals were completely anæsthetised.

10384. The whole question in this case, as in the last, seems to be whether slight anæsthesia means sufficient anæsthesia to prevent pain, or whether it means something less than that?—Yes.

10385. (*Colonel Lockwood.*) This same paper which you quote says, "The animals in question were completely anæsthetised and insensible to pain throughout the whole experiments"?—That is a general statement of the whole lot.

10386. (*Chairman.*) That is the statement, of course, of the physiologists there at work—I know you do not admit the statement—that though light anæsthesia it was complete anæsthesia in the sense of no pain being felt?—The word "ἀναίσθητος" means "without feeling, insensible." You must either be sensible or insensible. I decline to accept "slightly anæsthetised."

10387. We cannot press the derivation so far?—What does anæsthetised mean? It means without feeling. You cannot be slightly without feeling. You either feel pain or you do not.

10388. A drug which will produce anæsthesia means a drug which will produce that state of things, but whether a drug will produce that anæsthesia to a different extent, slight, incomplete, complete, and yet there may in each case be absence of pain on the part of the animal, I am not able to say. The term "light anæsthesia" seems to be used by physiologists, at any rate, as being an expression which does cover absence of pain?—If I may say so, I regard such expressions in

Hon. S. Coleridge.

19 June 1907

the mouths of physiologists as expressions for the purpose of putting them inside the Act of Parliament.

10389. The Act of Parliament says nothing about slight anæsthesia at all?—It does not.

10390. It says that the animals must be under anæsthetics?—Yes.

10391. And there must be no pain?—Yes.

10392. The Act is complied with whether you put the word "slight" in or anything else if there is sufficient anæsthetic to prevent pain?—Yes.

10393. It comes back to what I said, whether in the mouth of those who used the term, assuming them to be speaking honestly, which you do not admit, the words "slight anæsthesia" cover absence of pain; they say that it does?—My point is that when they say that it does they say it to cover themselves from the Act of Parliament.

10394. The whole question is whether it is true?—We regard it with profound distrust, and we believe that if a properly authorised inspector were present he would see that the anæsthesia was complete.

10395. It would no doubt facilitate our inquiry if we were to adopt your view that we should believe nothing that is said by physiologists, and that those who speak on the other side are to be believed?—I do not take that line.

10396. That is rather what you suggest?—No, I say that when a person's own conduct with regard to the Act of Parliament is impugned, it does seem to me somewhat inadequate to go straight to him, the person impugned, and to take, without any question, his explanation of what he did.

10397. It was only with reference to an expression that you used just now that I said that. You assumed that it was said by physiologists in order to cover up a breach of the law, or you used some such expression as that?—A man is accused of a breach of this Act of Parliament.

10398. Not until after he has used the words?—After he has used the words he is accused of a breach of the Act of Parliament; he is asked by the Home Office to account for himself. What could he do to put himself inside the Act of Parliament but say that the words that he used, whatever they were, were sufficient for the Act of Parliament. You could get it down to an infinitesimal amount of anæsthesia, and you would find that they would maintain, if they were asked themselves, that it was sufficient.

10399. (*Sir Mackenzie Chalmers.*) These are the gentlemen who themselves saw the experiments, and conducted them; who else could say whether the animal suffered or not?—Quite so. There should be an inspector there. That is my answer.

10400. (*Dr. Gaskell.*) Have you ever seen such an experiment?—No; as I have said already, I do not propose to assist any vivisector to break Section 6 of the Act.

10401. (*Chairman.*) I see in Gould's Medical Dictionary "anæsthesia," the condition of total or partial insensibility, particularly to touch"?—What is the date of that book? It is since the Act, I should think.

10402. It is 1900?—Exactly, that is since the Act?—Who is the author of it?

10403. I suppose Gould's Dictionary of the day would be since 1876?—But the definition of anæsthesia is brought up to date to fit the Act.

10404. You said the word anæsthesia in its medical sense?—No; I said in its English sense.

10405. No, in its Greek sense?—Yes, its Greek sense.

10406. But in its medical sense apparently there are some who contend that it means something less than that?—Yes.

10407. The dictionary is, I see, by Dr. George M. Gould, and it is published in London by H. K. Lewis, 136, Gower Street, 1900.

10408. (*Sir William Collins.*) It includes partial insensibility within the meaning of anæsthesia?—That is very important. Then I may take it that light anæsthesia as taken from that book does mean sensitiveness to pain, if that definition is to be taken.

10409. (*Chairman.*) Not from the book which I quoted from just now. This is of course the same gentleman who wrote the account, who said that at the time of the operation the animals were completely insensible to pain?—Now we are getting off the dictionary on to the views of the person.

10410. Of course I merely quoted the dictionary, but it does not govern it at all; it was not very material, but it was apropos of what you were saying about the true translation of the Greek word.

(*Sir Mackenzie Chalmers.*) May I read the next definition of anæsthetic? It is rather curious: "Anæsthetic, without feeling, insensible to touch or pain; a substance that produces insensibility to touch or to pain; diminished muscular action, and other phenomena. Anæsthetics may be general, local, partial, and complete."

10411. (*Chairman.*) That is not so material. I thought perhaps the gentlemen when they were writing their account had present to their minds the definition?—My contention is very simple. My contention is that slight anæsthesia means a condition not insensible to pain.

10412. And you complain of the Home Office not having treated that as an offence after its being brought to their notice?—I say that throughout the Home Office have constituted themselves the defenders of the vivisectors from criticism, instead of being the impartial judges. I go on to the next charge now. I charge the Home Office officials with having appointed inspectors who have displayed such bias that they have thought it their duty not to make detective efforts to protect animals from illegal treatment. That, I think, is almost admitted, but as I am on it I should like to go on to show the bias of other persons besides Dr. Poore. That charge is based upon an answer of Sir James Russell's to Question 530: "When I took office he" (that is Dr. Poore) "wrote to me to tell me that I was to visit registered places about three times a year, but he expressly said that I was not expected to act as a detective," that is to say he was to have more consideration for the vivisectors than for the animals. That is what it amounts to in my opinion. He was further asked at Question 532: "Have you been instructed to make surprise visits," and his answer was "Never."

10413. Yes; I remember the evidence?—Dr. Busk, who was Inspector from 1876 to 1886, alluded to the agitation conducted by my society as "a senseless and mischievous agitation." That is not a wholly impartial description of us, I should think. Then Dr. Poore resigned, or, anyhow, left the Home Office. He ceased to be Inspector in 1899 some time after the correspondence which I had over Dr. Crile, and he signalised his departure from office by making an oration called the Harveian oration, delivered at the Royal College of Physicians in London by him, and it was reported in the "British Medical Journal" of October the 21st, 1899, which is in the room. In that he says: "So with regard to another burning question there be those who apparently hold the view that a guinea pig is of more value than many babies" (I do not know whether he is alluding to me; I never valued a guinea pig above a baby); "and that operations on the lower animals, no matter how carefully they be done, if done for the purpose of research, diagnosis, or relief, and not with the object of making mutton tender, pigs fat, or horses quiet, are to be denounced as atrocities. With such as these it is useless to argue. But seeing that many honoured members of our profession have themselves been vivisected by the envenomed tongues and sharp pens of a few noisy people, it may be well to point out that no conviction for cruelty or breach of law has ever been obtained." For a very excellent reason, that is that the Home Office themselves, who were responsible for Dr. Poore being Inspector, would have to advise the Home Secretary to give assent in writing to a prosecution. It is not very likely that with Dr. Poore there we should have got assent in writing, "and that hearsay and the misinterpretation of physiological writings is not evidence, at least on this side of the Channel."

10414. Is that so, that the Home Secretary cannot issue a prosecution without the consent in writing of Dr. Poore?—No; I say that the Home Office themselves are responsible for Dr. Poore being Inspector, and he would have to advise the Home Secretary to give assent in writing to a prosecution.

10415. What you said was that it is easily explicable, because the Home Secretary could not issue a prosecution?—I did not mean that. What I mean is that we cannot issue a prosecution without the written

consent of the Home Secretary, who would go for advice to Dr. Poore.

10416. You did put it so that the Home Secretary could not issue it without the consent in writing of Dr. Poore?—I did not mean to say that.

10417. You mean that the Home Secretary must issue a prosecution, and that he would not issue it without consulting Dr. Poore?—We cannot begin a prosecution without the written consent of the Home Secretary, and the Home Secretary would certainly not give us that consent without asking Dr. Poore, and that is the man who says that we value guinea pigs above babies, and so on. He went on to say: "The money collected by these strange apostles of mercy is not spent in the law courts, where initial cross-examination would be possible, but in attempts to institute a sort of medical excommunication, and in efforts to dam the stream of charity by sophistical utterances such as Tennyson pronounced to be ever the blackest of lies. Meanwhile it behoves the medical profession to bear a wary eye lest fanatics should seek to impose immoral tests upon applicants for hospital appointments, tests, be it remembered, which would have excluded Harvey from the service of St. Bartholomew's. No hospital governor who coquets with tests of this kind can possibly command the respect of our college, nor can we admit that such an attitude towards research can do anything but harm to the cause of the suffering poor. In this country we have always wisely recognised the uses of opposition. The stability of our political organisation has been largely due to the fact that the party in power is subjected to the ruthless criticism of the opposition, the toad ugly and venomous, which wears yet a precious jewel in its head.' So it has been in medicine, where scientific advance has been checked not only by the criticism of the learned, but occasionally by the clamour of the prejudiced and ignorant." With regard to that ebullition of Dr. Poore's, which he made immediately after leaving the Home Office as Inspector, the moment he was free of his trammels, it seems to me that a man who made that speech must have exercised the most strenuous efforts to preserve his unbiassed attitude of mind towards anybody who criticised vivisectors. The Royal Commission on Vivisection in 1876, on page 21, said: "The inspectors must be persons of such character and position as to command the confidence of the public no less than that of men of science." I say that Dr. Poore, who made such a speech as that, could not command the respect of the public. I admit that he did not make it until he left the Home Office, but it is obvious that that attitude of mind could not have arisen in a day, and it is probable that he indulged in that sort of expletives when he was inspector. I think, therefore that the Home Office ought not to have retained him, and that he was quite an improper person to deal fairly between the poor animals and the vivisectors.

(*After a short adjournment.*)

10418. (*Chairman.*) Will you proceed with your next statement?—I come now to the extreme difficulty of finding out how these certificates are signed, and how long they are effective. I find from information from the Home Office that so far as I can make out, Dr. Poore himself signed certificates exempting their holders from using anæsthetics, and was supposed to inspect the same persons whose certificates he had signed. I venture to think that if these certificates are to be signed at all, and given to these vivisectors exempting them from the use of anæsthetics, it is highly unfortunate that the person who signs them should be the inspector himself.

10419. (*Sir Mackenzie Chalmers.*) In what capacity did Dr. Poore sign them?—Dr. Poore signed certificates before he was made Inspector, but those very certificates remained in force for some years after he was Inspector, and were effective. I venture to say that it would have been more proper if those gentlemen had applied to somebody else to sign their certificates when Dr. Poore became Inspector.

10420. (*Chairman.*) They have to be signed every year, have they not?—That, my Lord, is a question which I have found it impossible to ascertain. The Home Secretary in his place in Parliament said on July 24th, 1899, in the House of Commons: "All certificates expire on the 31st of December of the year in which they are granted."

10421. The certificate—not the licence?—Yes. I was speaking of certificates. Under that you would imagine, of course, that in the year when Dr. Poore was appointed Inspector, at any rate at the conclusion of that year, any certificate signed by him would have expired, and that therefore in the ensuing years the gentlemen who held his certificates would have had to go elsewhere to get fresh ones, but I found that some years after that, it was the fact that certificates were still being used, and held by persons who still held certificates signed by Dr. Poore. I therefore wrote to the Home Office and asked them about it. I stated that in the Yearly Report for 1899 "Dr. Thomas Stevenson is stated to have received a crtificate signed by 'the Professor of Medical Jurisprudence University College London.' Both the Medical Directory and Whitaker's Almanack for the current year give the name of Dr. G. V. Poore as the holder of this Professorship."

10422. Dr. Poore was appointed Inspector in 1891?—Yes, he had been inspector ever since 1891, and here in 1899 was a certificate still held, signed by a person called the Professor of Medical Jurisprudence University College, London, when both the Medical Directory and Whitaker's Almanack for the current year, 1899, gave the name of Dr. G. V. Poore as the holder of that Professorship. I therefore drew the attention of the Home Office to it, and after some correspondence, I received the following reply: "I am directed by the Secretary of State to point out that his answer"—that is to the question in the House of Commons to which I have referred—"was that the Inspector whilst holding the office of Inspector under the Act, had not signed certificates. The certificate to which you refer was signed by Dr. Poore, before he held the office of Inspector." So that it amounts to this, that although we are told that all certificates expire on the 31st of December in each year in which they are granted, in 1899 there was a certificate signed by Dr. Poore, according to the Home Office, before he was Inspector, which must be before 1891, still in force.

10423. Running for eight years?—Apparently so, though the certificates are supposed to expire on the 31st December in each year.

10424. (*Sir Mackenzie Chalmers.*) Is that all the letter?—I was going on. "I am to explain that it is necessary for Dr. Stevenson to hold this certificate in order that he may carry out his professional and official duties in connection with the investigation of poisoning, and it is not limited in time, but is kept in force from year to year by the annual renewal of Dr. Stevenson's licence." So that apparently, although we are told that these certificates expire every year, we are told on the other hand that they are kept alive every year.

10425. Dr Stevenson is the Home Office analyst in poison cases?—I do not know who he is, I will accept your statement.

10426. (*Colonel Lockwood.*) He is the man who gives evidence on trials?—Very likely. Therefore we are told in the House of Commons by the Home Secretary that all certificates expire on the 31st December of the year in which they are granted, whereas in the letter to me I am told that they are kept alive from year to year.

10427. (*Chairman.*) Not "they"?—Kept in force from year to year.

10428. What I understand the Home Secretary to say is that there is an exception made in that case, and possibly in some others, where a person is holding a particular official position and is only doing official work. That is what I should gather from his answer. I should not gather that there is no rule at all that an ordinary certificate expires on the 31st of December?—You must make what deduction you like. I do not make any deduction except that it is a very confused statement. The two statements, one on the floor of the House of Commons, and the other from the Office at Whitehall seem to be contradictory.

10429. It certainly seems to that extent that it would have been more accurate according to his second answer, if the Home Secretary had said, "With the exception of certain officers all certificates expire on the 31st December."

10430. (*Sir Mackenzie Chalmers.*) You did not get a further question asked in the House to explain it?—I do not know at this moment. I may have or I may not. I will proceed with this letter—there is a little more said: "It is the practice of this Department to make licences annual, terminating on December the 31st in

Hon. S. Coleridge.

19 June 1907.

each year; and all certificates, whether exhausted or not, cease to operate on that day, because no person can perform a prohibited experiment without a licence. But on the renewal of his licence the holder of a certificate which is not exhausted nor disallowed may proceed with his investigation, as he is not required by the Act to obtain a fresh certificate every year." That, I maintain, is a flat contradiction—"he is not required by the Act to obtain any fresh certificate every year," and in the House of Commons—"All certificates expire on the 31st of December of the year in which they are granted." The two statements are wholly contradictory and irreconcilable. I admit that the fact that Dr. Poore's certificates were kept alive for years after he was Inspector is not exact evidence of his having displayed bias; it is more evidence of the carelessness of the Home Office in not seeing that a man did not hold the two offices and inspect the men who held his own certificates. Before I pass from that I will just rehearse my charge. My charge is that the Home Office have appointed inspectors who have displayed such bias that they have thought it their duty not to make detective efforts to protect animals from illegal treatment.

10431. (*Chairman.*) Then what is your next charge against the Home Office?—My next charge is that I charge the Home Office officials with having made entirely disingenuous statements in their official utterances, and with having constituted themselves the mere spokesmen of the vivisectors. On page 4 of the Parliamentary Report for the year 1904 the Inspector, speaking of one class of experiments says: "All performed under licence alone and under Certificate C, 1,102 in number, are unattended by pain." I think that is a most improper statement for a Parliamentary Paper, which goes broadcast all over the world, and is taken to be an assertion of fact on the authority of a great officer of the State. As he cannot pretend that he or his assistant was present at the vast majority of these experiments, this statement can be of no more weight than the uncorroborated assertions of the vivisectors themselves, upon which alone it must be founded, and I therefore assert that it would be more becoming for the Inspector to say that these 1,102 experiments were stated by those who performed them to be unattended by pain. That is a proper statement for him to make. If he was an unbiassed official, why should he adopt and endorse the statement of the vivisectors that all these experiments were unattended by pain? It is a remarkable commentary on the sweeping declaration of the entire painlessness of experiments done under licence alone, that on page 77 of the very same Report four vivisectors in Ireland appear to have admitted that pain accompanied their experiments so conducted.

10432. (*Sir Mackenzie Chalmers.*) Ireland, of course, is not under the Home Office?—No; but are the animals in Ireland more sensitive to pain, or is the Inspector more truthful? If you will pardon my asking the question, I did not mean to put it in the form of a question. That seems, at any rate, a question that should properly have been put to Mr. Thane when he was here. Further down, on page 4, the Inspector commits himself to the following assertion in respect to experiments done under Certificate B, allowing the animals to survive their operations. I have the quotations here if anyone likes to verify them: "Experiments involving the removal of important organs, and even parts of the brain, are performed without causing pain to the animals." If this refers only to the operative procedures under Certificate B it is disingenuous, because we admit, at any rate, that if the law is followed under the operative procedures the anæsthesia ought to be complete.

10433. (*Chairman.*) Is that the Report for 1904?—It is issued in 1905 for the year 1904. I do not know whether the Inspector expects people who have operations performed on themselves to believe that animals do not suffer as they themselves have suffered after recovering consciousness. I do not know whether that statement is deliberately framed so as to relate in fact only to the period of unconsciousness, while it is intended to convey to the reader the idea that the whole experiment is without pain.

10434. These are all cases of recovery afterwards?—Yes, this is Certificate B.

10435. Would you mind reading the Inspector's statement again?—"Experiments involving the removal of important organs, and even parts of the brain, are performed without causing pain to the animals."

10436. "And"—would you go on?—I have not got it.

10437. (*Sir Mackenzie Chalmers.*) "And after the section of a part of the nervous system these degenerative changes are painless"?—That may be so.

10438. (*Chairman.*) That completes the sentence?—Yes. He does not even commit himself to saying that that is always done. In either case, I characterise this as an *ex parte* defence of vivisection and the vivisectors, and I think it is altogether unbecoming in a Government Inspector. On page 5 the Inspector writes a paragraph on inoculation experiments done under Certificate A, the plain object of which is to suggest to the public that no acute suffering occurs in such experiments. This is what he says: "The substance administered may give rise to poisoning or set up a condition of disease, either of which may lead to a fatal termination. To administer to an animal such a poison as diphtheria toxin, for example, or to induce such a disease as tuberculosis, although it may not be accompanied by acute suffering, is held to be a proceeding 'calculated to give pain,' and therefore experiments of the kind referred to come within the scope of the Act 39 and 40 Vict., c. 77." I call that a disingenuous statement. The Inspector cannot be unaware of the fact that terrible suffering accompanies death by tetanus, induced by inoculation under Certificate A, that very many of the 8,292 inoculations done on behalf of the Cancer Research Fund (I will not use the word Imperial myself in connection with such a thing) entail considerable and prolonged suffering. The animals were given diseases, and they must have entailed considerable and prolonged suffering, and that many of the 29,705 inoculations inflicted lingering and painful disease on the animals used. He must be aware of that. If he really is unaware of these facts, he could have learnt them with a little investigation. If he is aware of them, the paragraph is clearly disingenuous.

10439. Just read the paragraph again—the part that you say is disingenuous?—"The substance administered may give rise to poisoning or set up a condition or disease, either of which may lead to a fatal termination. To adminster to an animal such a poison as diphtheria toxin, for example, or to induce such a disease as tuberculosis, although it may not be accompanied by acute suffering, is held to be a proceeding 'calculated to give pain,' and therefore experiments of the kind referred to come within the scope of the Act 39 and 40 Vict., c. 77." I call that a disingenuous statement; that is covering up from the public eye, in a public Report, the fact that a great deal of very severe suffering is caused under Certificate A.

10440. You mean that it suggests that nothing worse, at any rate, can happen in those cases?—Yes, for example, he carefully takes the diphtheria antitoxin and tuberculosis as two cases which are very likely not accompanied by severe suffering, but he must be perfectly well aware that experiments are conducted in tetanus and other things which do cause very grievous suffering, and he ought to say so. He has admitted it further on in the evidence, but this was written before a Royal Commission was going to sit. In either case, whether he is really unaware of the fact that serious suffering follows Certificate A in many cases, or whether the paragraph is disingenuous if he is aware of it—in either case I ask whether an individual who is either ignorant of even elementary knowledge of the conditions of many diseases, or who writes disingenuously in a Government Report, is a proper person to be Inspector under the Act. On page 6 the Inspector says that he and his colleagues found the vivisectors "desirous of acting in every way in accordance with the letter and spirit of the Act." What in the world did the man expect? He need not assure the public that the vivisectors do not break the law when he makes one of his rare visits to the laboratory. The anterior portions of the Report sufficiently indicated the Inspector's own appreciation of the letter and spirit of the Act. And it would indeed be remarkable if the vivisectors found any fault with it. At the head of Table IV. (I am now coming to what the Department says, not the Inspector), and repeated on several pages, the Department makes the following statement:—"N.B.—In experiments performed under licence alone, or under Certificate C, the animal suffers no pain, because it is kept under the influence of an anæsthetic from before

the beginning of the experiment until it is killed." Now, I say that the Home Office themselves who issued that statement can have no authority for it but the assertion of the vivisectors. They have admitted that their Inspectors are not present at any part of the vast majority of such vivisections, and if the intention of the Act was, and is, that the Home Office officials are to constitute themselves the endorsers of the uncorroborated statements of the vivisectors no Inspectors would be needed or provided by the Act. The Home Office officials themselves simply assume and assert publicly in this statement on no authority but that of the vivisectors themselves that they never infringe the provisions of the Act, and they thereby set themselves in open antagonism to the law, I maintain which, by providing inspection, informs the Home Secretary that he is not to be satisfied by the uncorroborated assertions of the vivisectors. I venture, therefore, to assert that this "N.B." which I have quoted is a biassed *ex parte* assertion entirely unbecoming in a Government Report.

10440A. What is the evidence that you suggest the Home Office ought to get? Of course, they ought to have the account for what it is worth of those who actually perform the experiments?—I say that the proper heading would have been not to assert that when those experiments were performed the animal suffered no pain, but that the vivisectors informed them that in those experiments the animals suffered no pain. Then the public could take that assertion for what it is worth.

10441. Apparently their adviser, Dr. Poore, or whoever it was at that time, advised them that it was so?—Dr. Poore was no more there than you or I.

10442. So far as his evidence goes, he is the Inspector?—Yes, he is the Inspector.

10443. And so far as the value of it goes it was in the same direction apparently?—Whether a man be an Inspector or a policeman, or anything else, he cannot know what happens in places where he is not.

10444. Neither can the Home Secretary?—That is my objection.

10445. He does get the evidence of the people who were on the spot?—He gets the evidence of the vivisectors themselves.

10446. They were the people on the spot?—I should not have the least objection to their putting a heading "N.B.—In experiments performed under licence alone or under Certificate C, if the law is properly observed, the animal suffers no pain," or "The vivisectors inform us that the animals suffered no pain," but they say "The animals suffered no pain." They were not there. They have no right to say that, and that goes to the public as an authoritative statement.

10447. (*Sir Mackenzie Chalmers.*) They see a certain number of experiments, and that is a sample, is it not?—They saw one entire experiment in one year, I think—one physiological experiment throughout.

10448. I think they saw a good many?—I have an answer on that very point in the House of Commons.

10449. I want that point cleared up?—It is a vanishing point; what they see is absolutely a vanishing point. I do not blame them for that; they cannot be there unless the law makes it necessary. I will come back to that. I know I have got it. It is something very small, you may take it from me, and I can prove it. I want to draw attention to Question 206 on page 10 of the Minutes. This case was put to Mr. Byrne:—"To give an example, the other day an experimenter wished to have an experiment without anæsthetics in this case. He wished to feed kittens on cow's milk instead of cat's, and a certificate was granted that the experiment might be performed without anæsthetics," and the answer was "Such an application would be granted by the Home Office." My comment upon that is, is feeding a cat with ordinary cow's milk an experiment calculated to give pain? I regard that simply, if I may say so, as flouting those who hold the views that I do. That question and answer seem to me to be a sort of ebullition of a spirit of raillery. No anti-vivisector that I ever heard of would suggest that giving a kitten cow's milk was an act calculated to cause it pain and the necessity of going to the Home Office to license such a thing. It is an attempt to pour ridicule upon the whole of those who with me wish to stop grievous pain to animals. You do not suppose that I, or any of those whom I represent, would support anything so absurd as that.

10450. On that point the experimenter would have been liable to prosecution if he had not a licence?—Why?

10451. Because it is an experiment, and it is an experiment which may cause disease in the animal?—How could the experiment of giving cow's milk to a kitten cause pain? There is nothing in the Act to prevent your trying which of two dogs will first find a bun under a sofa.

10452. It is a feeding experiment, and the licensee applied to the Home Office for a licence, because the result of changing the food in that way might have been to cause disease, and he wanted to find that out?—I pass from that.

10453. It was considered, and the licence was granted?—I do not deny it.

10454. (*Chairman.*) I do not say that it is likely to do it, and it sounds to me very unnecessary, but supposing that the kitten had died from the change of diet, I suppose a complaint might have been made?—My Lord, those whom I represent are not that sort of people. I protest against that being given as serious evidence—that is all. Then at Question 231 (this is very important, I think) Mr. Byrne was asked, "Has any application to be allowed to prosecute a licensed person ever been made and refused?" "No," says Mr. Byrne, "no application has ever been made and refused. An offer to give the Secretary of State's consent was once made." We all see what that is meant to convey, that we have no case, and cannot go to the Court. My answer is, of course, that we cannot make an application. How am I, or any one of the public, to obtain evidence of breaches of the law in cases which are not public? We can get no evidence of what goes on in laboratories except from the printed and published admissions of those who do the acts, and a man who has done an illegal thing is not likely to publish it abroad. They sometimes do, but if they do it is generally six months afterwards, so that I think this innuendo here, that we have made no complaints because there are no breaches of the law, is a very improper one on the part of the Home Office. I should like them to explain to us how we are to prosecute, however badly the Act is carried out! The next question that I want to refer to is Question 248, "Is there no red tape there?" and the answer is, "No, it is a necessity under the Act; the Secretary of State is bound to act in that way. It is curious that of the 60 contraventions, quite a substantial number were contraventions indicating a keen desire on the part of the operator to provide greater security for the animal not suffering than the Act allows him to take." The suggestion there of Mr. Byrne is that the Act of Parliament forces a sort of cruelty apparently upon the vivisectors; that if they were to follow the Act they would have to be cruel. "If he has a certificate, for instance, authorising him to carry out a certain investigation" (this is the instance he gives, you see) "without anæsthetics, and he, in an individual case, thinking the anæsthetic will do no harm, applies it to save the animal pain, then he has committed a breach of the Act. The Secretary of State cannot help that at present under the existing law." I venture to submit to Sir Mackenzie Chalmers and the Commission that this is not so. He could do the experiment under licence alone, which does not compel him to kill the animal unless it is in pain after the anæsthetic has passed off, or it has been seriously injured. And therefore the whole of that answer, I think, is most unhappy and unfortunate.

10455. (*Sir Mackenzie Chalmers.*) That refers to Certificate A, does it not?—Certificate A permits him to omit anæsthesia; it does not forbid him to operate under his licence alone.

10456. He wants the animal to recover?—So it may under his licence alone.

10457. No?—Yes, pardon me.

10458. Take the case of an inoculation experiment—that is what we are really thinking of?—That is quite right. What Mr. Byrne here says, is that if he has Certificate A he is precluded from using anæsthetics while he injects whatever it is that he injects. I say that is not so; he can inject whatever it is he injects under his licence alone; because it says that the animal must, during the whole of the experiment, be under the influence of some anæsthetic sufficiently powerful to prevent its feeling pain; and then it says that the animal must, if the pain is likely to continue after the effect of the anæsthetic has ceased, or if any serious injury has been inflicted upon the animal, be

Hon. S. Coleridge.

19 June 1907.

killed before it recovers. But in an inoculation of this kind neither has any serious injury been inflicted upon it nor is pain likely to continue after the effect of the anæsthetic has passed off. Therefore there is nothing whatever in the Act to prevent a man using his licence for an inoculation experiment.

10459. (*Chairman.*) Is not this rather on the question of the amendment of the Act, which I understand you are going to deal with afterwards. This is hardly a charge against the Home Office. There seems to be a point which you do not agree with as to the meaning of the Act?—The point I am taking is that in his evidence, Mr. Byrne would have the public believe that the Act of Parliament forces upon him a necessity for inflicting pain. That is what I object to.

10460. I do not see that?—He says, "It is curious that of the 60 contraventions quite a substantial number were contraventions indicating a keen desire on the part of the operator to provide greater security for the animal not suffering than the Act allows him to take." I say that is not so.

10461. Giving anæsthetics when the Act did not really compel him to do it?—No, giving anæsthetics when the Act says that he must not, is what Mr. Byrne says. I say that the Act does not say that he must not; I say that the Act does not put that compulsion upon him.

10462. I cannot see how that is a charge against the Home Office?——

10463. (*Dr. Gaskell.*) The contravention of the Act was, that they did not take out Certificate B as well; that is what the charge says?—I am speaking of the licence alone.

10464. (*Sir Mackenzie Chalmers.*) But you could not use the licence alone for inoculating an animal for the purpose of producing disease. If you aim at producing a disease, say cancer, under that you require Certificate A; the licence would not do it?—Why not?

10465. Because you are going to produce a serious lesion in the animal by producing cancer?—Not if the original operation is painless, a mere prick of a needle.

10466. You require Certificate A for that?—If you do not administer anæsthetics; but you may administer anæsthetics, surely.

10467. But you are bound to kill the animal before it recovers?—No.

10468. (*Chairman.*) Is not this a thing to be discussed, if discussed at all, on the question of amendment of the Act. If the Act is not clear about it you think it should be made clear. I do not see how you can found a charge against the Home Office for taking a particular view of the Act which, after all, is not an inhuman view?—My objection to it is that, as it seemed to me, Mr. Byrne's evidence was rather conceived in a spirit of raillery against us.

10469. No, I remember his giving evidence upon that point?—Then I pass from that. Now in Hansard of the 30th May, 1902, there is an important statement by Mr. Ritchie—it must have been part of a speech: "With regard to vivisection, time did not admit of fully discussing the subject. As to the argument that animals suffered intense pain after recovering from the anæsthetic, he could assure the House that that was very easily overstated, because life was destroyed before return of consciousness in all cases, except those where special certificates authorising the keeping alive of the animal were granted. It might become necessary to appoint additional inspectors, but it would be absolutely impossible to ensure that an inspector should be present at all operations, for that would require an army of inspectors. No certificate was given except under the greatest precautions, and even where such certificates were granted, the animals had to be killed immediately the object of the experiment was attained." I wish the Commissioners to fully appreciate those words: "Immediately the object of the experiment was attained." "Before the certificate was issued the Home Secretary had to be convinced that every precaution would be taken that the operation would be conducted by a properly-trained person for an adequate scientific object. All possible means were taken to avoid causing animals unnecessary pain, the inspectors were most humane men, and so, generally, were the operators. He did not know that there had been any convictions under the Act." I must take those words: "And so generally were the operators," to be an admission by the Home Secretary that not in all cases were the operators humane men.

10470. I should think that was rather a forced construction of a Minister speaking in the House. I dare say he put in the word "generally" thinking, "I am not going to commit myself to the statement that there is no such thing as a hard-hearted operator"?—I just draw the attention of the Commission to that, that is all. I pass from that. And as regards the words "The animals had to be killed immediately the object of the experiment were attained," I have had considerable correspondence with the Home Office about the proceedings of Professor Starling with the brown dog, over which I had to pay damages in the Law Courts. I may point out that whatever Professor Starling did to the dog was not within the purview of the Law Courts on that occasion. The action was brought by Mr. Bayliss solely, and everything that happened before the dog reached Mr. Bayliss's hands was outside the purview of that action. But I have to point out (and I have pointed it out to the Home Office) that I have asked the Home Office repeatedly to tell me under what licence and certificate the first two operations by Professor Starling upon the brown dog were done. I have been wholly unable to get an answer from the Home Office to that very plain, simple question. I wish the Commission fully to understand the point. My point is this. Professor Starling, if he had Certificate B, performed two operations upon that dog, one in December, a long interval of time between, and then another operation in February, to ascertain whether inflammation had been set up in the intestinal, or, at all events, the internal parts of that dog, by the first operation. If he did that second operation under his Certificate B, it was his duty, according to the Home Secretary's own words and according to the Act of Parliament, to kill that animal "immediately the object of the experiment was attained." When he had opened that dog a second time, he had by that opening fulfilled the object of his experiment, which was to ascertain, in his own words in the witness-box, whether the condition of inflammation had been set up by the previous operation. Instead of immediately killing that dog, he handed it over to Mr. Bayliss, and left the building himself, and Mr. Bayliss performed a further major operation upon that dog, which took an hour. My contention is (and I have placed it before the Home Office with all the seriousness that I can) that in that case it was Professor Starling's duty to kill that dog the moment he had performed his second operation upon it, and that this handing of the dog round from one vivisector to another is utterly illegal and ought certainly to have been stopped by the Home Office if they knew of it. If they did not know of it, the evidence in the action brought against me apprised them of it. From the moment that that evidence was before the public, they knew that Professor Starling instead of killing that dog, handed it over to Mr. Bayliss. My contention is that there never was a case more clear of a breach of the Act. And if they say that the second operation performed by Professor Starling was not done under Certificate B, but done under his licence alone, then it was also his duty immediately to kill it on recovery from the anæsthesia. He had no business to leave it to anybody else. So that whatever view they have of it, Professor Starling must in my opinion, have broken the law.

10471. You have read Professor Starling's account of it, have you not?—I heard his account given in his sworn evidence in the witness-box.

10472. And also his account before us?—Yes, I believe he was examined.

10473. (*Sir Mackenzie Chalmers.*) Do you accept his account?—I do not know at the moment that I remember it. I am going much more upon the evidence given in the Law Courts and the subsequent action of the Home Office. The Home Office, at any rate in the long interval between that action against me and this Commission, did not know what Professor Starling was going to say to the Commission, and they did know what he said in the Law Courts, and upon what he said in the Law Courts they ought to have acted, in my opinion.

10474. (*Chairman.*) I am not sure whether I remember rightly myself—I have not referred to the evidence, and it was some time ago—but was it not a fact that the dog was under anæsthesia at the time that it was handed over to Dr. Bayliss?—That was a matter of dispute. There was sworn evidence on both sides.

But I am not dealing with the question of anæsthesia; I am dealing with the question of Professor Starling's duty to destroy that dog.

10475. I am not myself arguing the question whether it was a breach of the law or not; I am only trying to get at what the explanation was; I am not saying what the worth of his explanation was, but I understood his explanation to be that the animal was under anæsthetics; and instead of that dog being killed under anæsthetics, and a new dog being obtained and put under anæsthetics and operated upon by Mr. Bayliss, he allowed this dog to be operated upon. It had to be destroyed, and he thought that as it had to be destroyed without coming out of the anæsthesia, it was saving, as it were, another dog for Dr. Bayliss to make his experiment on that same dog. Whether that was a breach of the Act I am not saying—I dare say it was, but that was the explanation that he gave.

10476. (*Colonel Lockwood.*) Did not Mr. Akers Douglas give me the same answer about that very question in the House of Commons?—Yes, I think he did. My point is that the animal under Certificate B had a right to be killed the moment Professor Starling had performed that second operation.

10477. (*Chairman.*) I quite see the point?—Professor Starling handed it over to somebody else; he did not even stay to see whether the animal remained under anæsthesia. It is his duty to see; it is not his business to hand it over to anybody else. To pass dogs round from hand to hand and nobody is responsible: to wash his hands of it and give it to somebody else is not, in my opinion, the way in which this Act should be carried out. I also wish to point out that if it had not been for this action the veil would not have been lifted in this case; we should not have known that the animal was handed from one vivisector to another, and passed round with wounds clamped up in its side with iron pincers. And this may happen constantly. The inspectors have told me that they knew nothing about the case until the action was brought. I have been told by the Home Office that they knew nothing about it. Now I come to the latter part of this charge, which is, that the Home Office have constituted themselves the mere spokesmen of the vivisectors. The position of mere spokesmen of the vivisectors has never been so openly exposed as in their own Reports. In the Report issued for 1879 when Mr. Busk was the Inspector, this is what he said: "The number of experiments performed, and according to the returns I have received from each licensee, was about 481." First of all he says "about," which is a very ingenuous remark to make; he does not know the number of experiments, and even the "about" is simply based upon the returns which he has received from each licensee, so that one licensee may have performed a thousand experiments, and there is nothing to prevent his reporting it as one, two, five or six. It is a very remarkable thing that year after year a large number of licensees take the trouble to take out licences and certificates, and, according to their own account, never use them. I do not assert anything, but it is a matter of comment. If a man takes out a licence to drive a cab, you generally assume that he drives a cab; and if a man takes out a licence or certificate to enable him to vivisect animals without anæsthetics, it is somewhat strange if he does not use them. And he takes considerable trouble to get them, if they are to be renewed every year, according to one statement of the Home Secretary. In the Report for 1880 I find these words—still Mr. Busk: "In none of the other experiments under these certificates, as I am assured by the experimenters, was any appreciable suffering inflicted." That is the statement put forward, and that is a perfectly right and proper statement to put forward. He says: "As I am informed by the experimenters." If the Home Office always confined themselves to saying in their Reports that they were only assured by the experimenters that this and that did not happen it would be more fair to the public. But still, as I have said, they remain simply here the spokesmen of the vivisectors—that is all. In 1883 he says: "I have been assured by all the experimenters, that in this class of cases no appreciable pain was manifested." There again he is nothing but the spokesman of the experimenters. Then in 1883, further on, he says: "In none of these experiments, as I am informed by the experimenters, was any appreciable pain inflicted." In 1884: "No appreciable suffering would be caused if the provisions of the Act were faithfully carried out, which I have every reason to believe was done." Well, down to the word "carried out" that is a very proper statement. "Which I have every reason to believe was done," is a statement that we will take for what it is worth. He was not there, and I do not see how he can say. He may have every reason to believe. I suppose that is a harmless statement; it does not carry much weight. This is the next Report, still 1884: "From the returns I have received from the various operators, it would appear that no pain was inflicted in these cases except in about 14 or 15 instances, in which disease was produced, but which was very trifling." There again he is merely their conduit pipe. Then the Report for 1885: "No appreciable suffering would be caused if the provisions of the Act are faithfully carried out, as there is not the least reason to doubt they were."

10478. You are not objecting to any of these statements that you have read?—I am only saying that throughout their Reports, and on all occasions, the Home Office constitute themselves the mere spokesmen of the vivisectors. They incorporate in their Reports just exactly what the vivisectors tell them. I say, and say it frankly, that in these Reports they say the vivisectors tell us they do not inflict any pain.

10479. That is rather a different thing from being mere spokesmen?—It comes to that. They do not criticise.

10480. When we speak of a man being the mere spokesman of somebody else, we mean that he is put forward to present that person's views in his interest. This is merely saying "I have merely to report information I have received, and this is the information I have received"?—I do not mean to convey any more than that, except that in their Reports, owing to their being wholly unable under the present Act to be present at vivisections that take place, they constitute themselves merely the spokesmen.

10481. We quite understand now what you mean by the word "spokesman." But we had better come to something about which you do complain of the Home Office?—I do not want to carry it any further than that. Now, in the "British Medical Journal" of the 18th June, 1898, Dr. Cecil Shaw, at page 1582, says: "My own work has consisted of two proceedings—first, the pathological examination of eyes removed on account of injury; and, secondly, an experimental research to determine what changes, if any, follow prolonged irritation of one eye, both with and without traumatism." He subsequently continues the narrative as follows: "In the experimental research my aim was to discover"—I am emphasising the "my," because he subsequently said that he never did any of these things himself; he says, "My own work," and he goes on subsequently "My aim was to discover whether prolonged irritation, external or internal, of a rabbit's eye would produce any visible organic changes in the ciliary region, either in the irritated eye or in the other. In the first experiment the eye was cocainized, and a wound was made in the ciliary region, without antiseptic precautions, and the cornea irritated with powdered jequirity seeds for varying periods up to six months. The jequirity causes purulent conjunctivis." (I do not understand all these words) "and abundant cocci were present in the pus, but though in some cases the ciliary region was again wounded while the eye was bathed in pus, no iritis was caused. In one case there was an extensive ulcer of the cornea, which ultimately healed without perforating. The non-irritated eyes were examined at intervals with the ophthalmoscope, but no departure from the normal appearance of the disc was seen in any case. Internal irritation was then tried, small shot being inserted into the eye, again without antiseptic precautions. In fact, soiled instruments were purposely used, to reproduce as far as possible the kind of wound which is most often found to cause sympathetic ophthalmia. When the incision was made in the sclerotic a few millimetres above the corneal margin, a little vitreous escaped on the shot being put in, but the wound healed rapidly, and in a few days no sign of it, or of external irritation, could be seen. When the wound was made in the ciliary region, more external irritation was seen. In one case the wound opened after several days, the shot was expelled, and all signs of irritation disappeared. In another, the shot was similarly expelled, but after some weeks, and irritation is still present at the end of five months, as shown by injection in the neighbourhood of the wound,

Hon. S. Coleridge.

19 June 1907.

but no signs of iritis are to be seen, either in the traumatised eye or in the other. This rabbit I have kept alive to observe how long the irritation lasts, and whether it will yet lead to any changes in the iris or ciliary body. After periods varying from three to four months, the rabbits were killed."

10482. Where was that performed?—In Dublin, I think.

10483. (*Dr. Wilson.*) In Belfast, I think.

10484. (*Chairman.*) In the United Kingdom, at any rate?—Yes.

10485. (*Sir Mackenzie Chalmers.*) That had nothing to do with the Home Office?—I have not said so yet.

10486. You were dealing, I thought, with your charges against the Home Office?—I identify ———

10487. The Irish Office with the Home Office?—Oh, yes.

10488. Not for all purposes, I hope?—I look at this from the point of view of the animals, not of the officials.

10489. I understand?—On inquiry I found that the alleged author of these experiments had never held a licence under the Act, much less the certificate which would have been necessary for such experiments as those above described. It looked, therefore, very much as if there had been a breach of the law. Special inquiries were made on the subject, and the society's solicitor went to Belfast to continue those inquiries on the spot. It was found impossible, however, to fix the exact date of the experiments, which was necessary as a preliminary to bringing the matter before any court. That shows the difficulty we have about bringing law actions. The inquiries were, nevertheless, persisted in for some time, but unfortunately the proceedings of vivisectors under the present law are carried on in such secrecy that it was found impossible to obtain the necessary evidence from any independent source. As a last but not very hopeful resource it was determined to lay the facts before the Irish Government. The correspondence which followed shows what happened.

10490. (*Chairman.*) When was this?—This was in 1898. I got a letter from J. B. Dougherty, dated from the Chief Secretary's Office, Dublin, and he encloses the correspondence, and here is the correspondence. It is a letter from Dr. Shaw to his very good friend Dr. Lorrain Smith, who had a licence, and a letter from Dr. Lorrain Smith to his very good friend Dr. Shaw, who had not. The letter from Dr. Lorrain Smith, who had a licence to his friend Dr. Shaw who had not, is as follows; both of them are dated the same day; they must have met in the street and exchanged them, I daresay: "Sir,—On receiving your note of yesterday's date, I referred the matter to Dr. Shaw, and I beg to enclose his reply. I regret that his paper is so worded as to be possibly misleading in regard to the vivisection experiments on inflammation of the eye which I allowed him to use. These experiments are performed by me" (this is the man with the licence) "in investigating the process of inflammation, and for them I hold the necessary certificate. I may further state that I reported the experiments in question to the Chief Secretary at the end of 1897 amongst other similar experiments on the process of inflammation. The experiments in which I as director of the laboratory aided Dr. Shaw were not on living animals." Now Dr. Shaw writes to his friend Dr. Lorrain Smith: "Dear Dr. Lorrain Smith,—I regret that any ambiguity in expression in my paper on sympathetic inflammation in the eye should have given rise to a misunderstanding. Your aid and advice were given in the whole course of the research, which included many bacteriological and other experiments, besides those involving vivisection. These latter, very few in number, were, I understand, part of the series of your own experiments on inflammation, of which you allowed me to make use. I had no responsibility beyond taking notes, and undertaking subsequent histological examination of the tissues.—Very sincerely yours, Cecil E. Shaw." So that Mr. Cecil Shaw, who in the papers said "my own work consisted of this, that, and the other," and "in the experimental research my aim was to discover"; and "this rabbit I have kept alive to observe," and so forth, when asked by the authority to explain how he did this says: "Oh, it was not I; it was my friend Mr. Lorrain Smith. I am sorry if there is any ambiguity of expression in my papers." I can see no ambiguity of expression. It is, "this rabbit I have kept alive," not "my friend Mr. Lorrain Smith."

10491. Is it now your suggestion that those two gentlemen were saying what is not true, and that Dr. Cecil Shaw did these experiments?—That is my suggestion. He said so himself in the paper which he published, and I prefer his statement written by himself before he was hauled over the coals to his refusal to say so afterwards.

10492. (*Mr. Ram.*) By the statement he made himself, do you mean what you have just read to us?—Yes, in his paper. "My own work consisted of two proceedings," and "in the experimental research my aim was to discover."

10493. I did not know whether there was anything else. I was not sure whether you alluded to that or any other paper?—No, I have nothing else to go upon but that paper.

10494. (*Chairman.*) Do you really think that that ambiguity —— ?—I see none.

10495. Well, what appears to you to be an incorrect statement but to other persons apparently an ambiguity?—When you say other persons, the person who called it ambiguous is Mr. Cecil Shaw himself.

10496. When I heard the explanation it is quite capable, to my mind, of being an ambiguous expression. If there had not been any other evidence I should have thought he was speaking of his own work. I should not have known that there was another operator; but I can quite understand if there was another operator how Dr. Shaw should have written that; and that being so, it seemed to me that we require rather more evidence, if we are asked to say that these two gentlemen have concocted a lie, than a mere suggestion that those words are a distinct and express admission by Dr. Cecil Shaw that it was his hand that operated, and not Dr. Lorrain Smith's?—Very well, then, I will supply you with that extra evidence that you want. New light was thrown upon what I consider the somewhat discreditable proceedings in the "British Medical Journal" of 22nd July last, on page 220, of which you will read in the report of the Scientific Grants Committee for the past year the following: "Shaw, C.E., M.A., M.D., 14, College Square, East, Belfast.—For a research on sympathetic ophthalmia, necessitating the purchase of monkeys and dogs and apparatus, £12." I call that corroborative evidence that he, Dr. Cecil Shaw, is the person who did those experiments, because he was given money to do them, and to purchase monkeys, dogs, and apparatus for the purpose.

10497. I understand your point about it?—And, further down—I have not quite finished yet—the editor of the "British Medical Journal" himself does not attempt to conceal the truth as I hold it about Dr. Cecil Shaw, because he says on page 224: "Dr. Cecil Shaw has, owing to circumstances, had to abandon for the present the research for which he received the grant." Putting all that evidence together, I maintain that that is sufficient evidence for reasonable people that Dr. Cecil Shaw did those experiments himself, and that when the Home Office, represented by the Irish Office over there ——

10498. (*Sir Mackenzie Chalmers.*) Oh, no, no, the Irish Office does not represent the Home Office?—Whatever it is—whatever is the Home Office over there in Ireland——

10499. (*Chairman.*) Supposing that Dr. Cecil Shaw had undertaken a research of this kind, and thought it was one that would yield useful results, supposing he had not got a licence, and got his friend, who had a licence and a laboratory, to do the manual work that was necessary, would not everything then be consistent? Would not this passage about the grant and everything else all be consistent?—No, I venture to think not. I think if a man gets a grant to do a thing himself——

10500. It does not say himself; it says his research. It does not say that his hand is to be the hand to operate upon those rabbits?—But he says himself, "My own work."

10501. We have gone through all that, and I have said what the effect is upon my mind?—I must beg leave to say that the effect on my mind is very different—that is all.

10502. So I understand.

10503. (*Mr. Ram.*) Your charge here is the illegality of any operation of this sort being performed by this particular man?—My charge is a little more than that. My charge is that when a person performs what is, in my opinion, a totally illegal act, and a knowlege of

that fact is brought by me to the officials who are his superior officers, instead of listening to me and saying to this man: "You have no business to do this," they always adopt his explanation, and throw it back at me, and say that is the explanation.

10504. (*Chairman.*) What they did was they accepted the statement of Dr. Cecil Shaw and Dr. Lorrain Smith?—Yes, at once. They had not at that moment, of course, before them the statement about the grant to Dr. Shaw himself for doing the very thing, because I had not got it to lay before them at that moment; otherwise it possibly might have led to a little difference. The answer of the Home Office was this: "With reference to previous correspondence relative to alleged violations of the Act 39 and 40 Victoria, chapter 77, by Dr. Cecil Shaw, of Belfast, I am directed by the Chief Secretary to transmit to you the accompanying copies of letters from Dr. Lorrain Smith and Dr. Shaw" (those are the two I have read). "I am to add that, having regard to the contents of these letters the Irish Government cannot carry the matter further." My complaint is that they immediately accept what I call the absurd explanation of these two vivisectors.

10505. (*Sir John McFadyean.*) Might we ask what it is suggested that the authority ought to have done under the circumstances?—They ought to have prosecuted Dr. Shaw for performing a very cruel experiment upon these rabbits without any licence at all.

10506. (*Chairman.*) The specific evidence against him would have been that statement, "My own work"?—They could get evidence that I, as an outsider, could not. They could have got the laboratory attendants and everybody in connection with that laboratory, and got to the bottom of it; instead of which they accept immediately, without any further talk, these two, as I call them, ridiculous letters of these two gentlemen.

10507. (*Dr. Gaskell.*) Is not the case of Ferrier and Yeo a very parallel case?—Yes.

10508. Was not that brought by you to the Law Courts?—It was before my time. I think it was brought by the Royal Society for the Prevention of Cruelty to Animals. I can find out all about it for you.

10509. Did not the Law Courts say that the evidence was distinctly that although Ferrier used the word "I," and spoke of them as his experiments, and got the money for the very purpose, the experiment was really done by Yeo?—I dare say.

10510. It was a parallel case?—I do not know.

10511. (*Mr. Ram.*) Was that before a jury?—I think it was before the magistrate; I do not think there was a jury upon it at all.

10512. (*Colonel Lockwood.*) Is that the end of your charges against the Home Office?—Oh, dear me, no.

10513. (*Sir Mackenzie Chalmers.*) We have been divagating to the Irish Office, and now we are coming back to the Home Office?—I did not really recognise much distinction. The general effect, I only wanted to say, of Dr. Cecil Shaw's case, in my mind, and I hope in the mind of yourself and others, is that—I do not say the Home Office in this case—the Irish Office did on that occasion certainly constitute themselves practically the representatives of the vivisectors—the spokesmen of the vivisectors.

10514. (*Chairman.*) Then what is your next charge?—I am here to charge the Home Office officials with having accepted the suggestion made to them by some nameless adviser, that to starve animals for days is not cruel, when they must perfectly well know that if any one of them starved their own horses (if they have any) the nearest policeman could successfully prosecute them for cruelty to animals under Martin's Act. That is the next charge I make. It is based upon this evidence. The "Journal of Physiology," volume xix., page 193, contains an account of great cruelty inflicted on animals by Dr. Noel Paton. On page 193 he tells us he starved a kitten for 56½ hours; on page 194 he tells us that he starved two pigeons for 96 hours; on page 199 we read: "Experiment 38. Three young rabbits of a brood, procured on June 7th, and starved to June 9th." I asked the Home Office whether the certificate under which these cruelties were perpetrated was Certificate A, and I asked what were the names of the professors who signed that certificate; and I further asked whether, in the opinion of the Home Secretary, starving animals for days together is correctly described as a "trivial operation," because Certificate A, we have been told, is only issued for trivial operations. The answer was that they had communicated with Dr. Noel Paton, and that they had ascertained from that gentleman that the experiments were not performed under any certificate specified in the Act.

10515. Did Dr. Noel Paton say what the object of the experiment was?—I do not know what his object was. I take no more interest in the object than the poor kittens did.

10516. (*Sir Mackenzie Chalmers.*) You got the information from the "Journal of Physiology"?—Yes.

10517. Did not it state any object?—I dare say it did. I take no interest in the object.

10518. (*Colonel Lockwood.*) "On the Relationship of the Liver to Fat," by Noel Paton?—Yes; I am not a doctor; I take no interest in the relation of the liver to fat; I do take an interest in pain inflicted on animals. It is perfectly indifferent to me what his object was.

10519. (*Chairman.*) You are aware that we are also discussing the question of breaches of the Act?—Yes, but the Act does not say what the intention was.

10520. But it says "With a view"?—Yes, that I do not know.

10521. (*Mr. Ram.*) You said that you asked the Home Office three questions. What was the answer to the first?—The answer was that the gentleman said that the experiments were not performed under any certificate.

10522. Then the second one?—The second one falls with it; it was to ask who the people were who signed the certificate. That falls with it. The third was whether starving animals was considered a trivial operation.

10523. Was there any answer to that?—The Home Office Secretary does not commit himself to that; he would not answer it. I will give you the whole letter: "Sir,—With reference to your letter of the 9th ultimo, I am directed by the Secretary of State to acquaint you that he has made inquiry as to the experiments to which you refer as having been performed by Dr. Noel Paton, an account of which is contained in the 'Journal of Physiology' of 1895-6. He has ascertained from that gentleman that they were not performed under any certificate specified in the Act 39 and 40 Vict., cap. 77." That is the whole letter. They will not tell me whether they consider it a painful operation or not.

10524. (*Sir Mackenzie Chalmers.*) If the experiments were cruel they would come under the general law of cruelty to animals?—No, not if they are experiments.

10525. Why not? Surely if a man has no licence it comes under the general law of cruelty to animals?—Yes, of course, if he is not licensed.

10526. Here he had no licence, apparently?—I did not say that; I said he had no certificate. I think he had a licence. I did not make that point. I assumed, of course, that he was a licensee, and I feel sure that he was. If he was a licensee and was doing painful experiments, I say he comes under the Act. I think he is a licensee. If he is not, I should have been sure to ask the Home Secretary how it was that he did these experiments without a licence.

10527. (*Mr. Ram.*) Unless he had a licence there was no good in going to the Home Secretary?—Exactly; I feel sure that he had. I feel sure that I should have asked that.

10528. (*Sir Mackenzie Chalmers.*) Dr. Gaskell thinks he had a licence?—I deduce it from my letter. The point is, here is a licensee who does a peculiarly, in my opinion, painful experiment. If he does it under his licence alone, he is bound to see that the animal during the whole of the experiment is under the influence of an anæsthetic sufficiently powerful to prevent its feeling pain. You cannot keep an animal for 56 hours, I presume, under chloroform?

10529. If he does it outside his licence altogether he comes under the general law of cruelty to animals, surely?—I hardly think so.

10530. He did not purport to do it under his licence at all?—Until he informs you that he considers the experiment outside his licence the natural assumption is that it is inside his licence. It is an experiment

Hon. S. Coleridge.
19 June 1907.

that comes under the Act, and the Act deals with experiments on animals. He does not make the defence that he is doing anything else; it is not like a carter driving a horse with collar sores; it is an experiment. If this does not come under the Act, nothing does. I next asked the Home Office the following questions: "(1) Were the kittens that he starved for 56½ hours, the two pigeons that he starved for 96 hours, and the three young rabbits starved from the 7th to the 9th of June kept under the influence of anæsthesia during those hours and days mentioned respectively, and if so, what was the anæsthetic employed? (2) If these animals were not so kept under the influence of anæsthesia, and, consequently, if the law was broken, was a prosecution instituted by the Home Secretary against Dr. Paton; and if not, what course, if any, was adopted by the Home Secretary to punish Dr. Paton for breaking the law, and to secure his future obedience to it? (3) Whether Dr. Paton holds a licence and certificates at the present time, and if so, who signed his certificates and his recommendation for a licence?" I did ask the question, you see, in that letter. (*After referring.*) Yes, here he is; he is a licensee, and he had a licence at that time. The answer was: "Sir,—With reference to your further letter of the 5th inst., regarding certain experiments described in Volume XIX. of the "Journal of Physiology," I am directed by the Secretary of State to say that he is informed that Dr. Noel Paton, after careful consideration, did not deem these experiments to be within the scope of the Act 39 and 40 Vict., c. 77. The Secretary of State is clearly of opinion that experiments involving starvation to an extent calculated to cause pain would be within the Act; but the inquiries he has made point to the conclusion that the extent and degree of pain which animals suffer from deprivation of food is a matter of considerable doubt. In any case, Sir Matthew Ridley does not propose to institute proceedings in respect of experiments which were conducted so long ago as 1895-6 and not brought to his notice at the time. Dr. Paton holds under the Act a licence and certificates, particulars of which will be found in the Annual Return of Experiments upon Living Animals for the year 1899." My reply was: "Sir,—With reference to your letter of the 30th of July, 1900, in which you inform me that in Dr. Noel Paton's opinion his experiments were not within the scope of the Act 38 and40 Vict., c. 77, what I desire respectfully to inquire is, not what Dr. Noel Paton's opinions may be of his own experiments, but whether, in the opinion of the Home Secretary, the starving of animals, described by Dr. Paton, were experiments upon living animals within the meaning of the Act." I cannot get an answer.

(*Mr. Ram.*) I thought he had answered that.

10531. (*Colonel Lockwood.*) He evaded it rather?—Yes, and he goes on evading it: "Sir,—With reference to your letter of the 27th ultimo, inquiring whether the Secretary of State considers the starving of animals described by Dr. Paton were 'experiments' within the meaning of the Act, 39 and 40 Vict., cap. 77, I am directed by Sir Matthew Ridley to inform you that, for the reasons given in the letter from this Department of the 30th ult., he decided not to cause proceedings to be taken against Dr. Paton. He therefore deems it unnecessary to express an opinion in the case of Dr. Paton whether or no his contention was correct, and whether or no what he did was an experiment upon living animals, such as to come within the provisions of the Vivisection Act."

10532. (*Mr. Ram.*) Would you read the first letter of the Secretary of State again in answer to your first letter on the subject?—"Sir,—With reference to your letter of the 9th ultimo, I am directed by the Secretary of State to acquaint you that he has made inquiry as to the experiments to which you refer as having been performed by Dr. Noel Paton, an account of which is contained in the 'Journal of Physiology' of 1895-6. He has ascertained from that gentleman that they were not performed under any certificate specified in the Act."

10533. Yes?—That is all, except "Your obedient servant, Henry Cunynghame."

10534. I thought there was some sentence that you read before that the Home Secretary was of opinion that these things did come within the Act?—No, that is the only letter. He rehearses what the other man said. Perhaps you are thinking of this: "I am directed by the Secretary of State to say that he is informed that Dr. Noel Paton, after careful consideration, did not deem these experiments to be within the scope of the Act." "The Secretary of State is clearly of opinion that experiments involving starvation to an extent calculated to cause pain would be within the Act."

10535. There is a distinct answer. I thought he had given one?—Yes, but he did not tell me whether these were such experiments.

10536. That is a direct answer to the question you asked?—No; I wanted to know what these experiments were. I do not want a general statement that there may be starvation, no doubt.

10537. Surely the general contains the particular?—No; he says: "Starvation to an extent calculated to cause pain would come under the Act." That is obvious. I did not want him to tell me that. I wanted to know whether he considered that Dr. Noel Paton's experiments were experiments painful under the Act; and he would not tell me.

10538. He could not tell you that unless he knew what the feelings of the animals were?—I think if you starved a horse for 96 hours he would soon know. I think under the ordinary law there are a very large number of convictions every year through the Royal Society for the Prevention of Cruelty to Animals for the very offence of starving animals. I also want to point out this—there is another point which arises out of this: "In any case Sir Matthew Ridley does not propose to institute proceedings in respect of experiments which were conducted so long ago as 1895-6, and not brought to his notice at the time." The "Journal of Physiology" is a publication that certainly must be within the purview of the Inspector of the Home Office. It is the journal of the vivisectors; and to say that a paper in it was not brought to the Home Secretary's notice at the time, one of two things must have happened; either Dr. Noel Paton did not fulfil the instructions that we are told are given to all vivisectors under the Act, to forward to the Home Office papers that they publish describing any experiments that they perform——.

10539. (*Sir John McFadyean.*) That they perform under the Act. His contention was that it was not under the Act?—But I think you will find that these experiments of Dr. Noel Paton are in a volume that must have gone to the Home Office—the "Journal of Physiology."

10540. (*Chairman.*) But if it was in 1895 how could the Home Secretary prosecute. It would be too late to prosecute summarily five years afterwards?—I am going to say that the "Journal of Physiology" ought to have reached him as soon as it was published.

10541. But taking his letter in 1900, he was quite right, was he not, in saying that it was too late to prosecute?—Very likely. What I am upon is this: It is almost the invariable rule that vivisectors, so far as I can see, never publish an account of their doings until a good six months after those doings have been completed, so as to escape any possible prosecution under the Act. The Act prevents any prosecution six months after the event, and we can only find out what happens in laboratories at secondhand, either from the publications of the vivisectionists, or from the Annual Report of the Home Office, which itself is generally only published three or four weeks before the expiration of the six months.

10542. I only asked the question, because from the Home Secretary's letter there might appear to be a discretion with him as to whether he should prosecute; but in fact the period for prosecution was up?—That is not the point. The point is that Dr. Noel Paton's assurance that he did it outside the Act is immediately accepted by the Home Office. It seems to me that a perfectly impartial person at the Home Office would have said, "These are painful experiments, they are done by a man outside the Act; he has done them outside the Act, and we will withdraw his licence from him or inflict some kind of censure upon him." Now I turn to Question 89 in the evidence of Mr. Byrne. I just want to show that this ought to have got to their notice—I think it ought, at any rate: "Now as to the records and reports of experiments which under statute a licensee is obliged to make, have you any observations to make as to the way in which that is complied with? Is that enforced by the Home Office?" and his answer is: "Decidedly it is enforced by the Home Office." Then the next question is: "Do you find that such records and reports are sent in regularly by the

licensees?" and then it goes on. I take all this evidence down to Question 94 practically to amount to an obligation placed upon vivisectors to send in any publications they make of their experiments. I think Dr. Noel Paton ought to have sent it in.

10543. (*Sir Mackenzie Chalmers.*) There is no obligation to send it in within a very short time. They ought to send it in soon?—I do not know what your regulations are, of course. You see, every day's delay puts a man further and further out of the possibility of prosecution under the Summary Jurisdiction Act.

10544. (*Mr. Ram.*) You are going to deal later on with the alteration of the present law which your Society purposes?—Yes.

10545. It may come up then, perhaps?—Yes.

10546. (*Chairman.*) Have you arrived now at any convenient stopping point in your evidence?—I will just finish this one charge, if I may?

10547. If you please?—Here is the answer to Question 95, which I think is important: "It is partly that and it is partly from the fact that if the supervision by the Home Office of an investigation going on in the country is to be anything like complete it will involve the examination of all the published investigations—investigations as to which anything is published," and so forth. That, I think, shows that this thing ought to have been sent in. And here, again, from Question 97 onwards: "The papers sent to the Home Office are usually not mere descriptions of experiments, but relations by a doctor of the steps of an important investigation which he is carrying out, or the progress he has hitherto made," and so forth.

10548. Does not this relate rather to the question of amending the Act, as Mr. Ram says, rather than any charge?—Perhaps. The effect of the evidence from Question 95 down to 102 comes to this. I think the evidence amounts to an admission on the part of Mr. Byrne that the Home Office have no means whatever of finding out if and what suffering is inflicted upon animals. That is what it comes to. The Home Office cannot judge. Look at Question No. 101: "Why not? (A.) Because the report (which I call a record and report) sent to the Home Office is a mere list of the experiments which he has performed under various headings" (that is the thing he makes his report upon). "It is in no way a description of the experiments." So that by the official things sent in to them they cannot judge what suffering is involved at all. And, broadly, my contention there is that the Act is so administered as to put the considerations of science above those of humanity; whereas the intention of the Act was to put humanity first.

10549. Does that conclude your specific charges against the Home Office?—No, that has got down as far as Charge 5, and there are seven more.

10550. Might I suggest that you might look over those seven and see whether you cannot shorten them, because there are some of these five that I think were matters too small to have much effect upon one's mind, and if you look through your seven other charges you will probably find that you can shorten it?—Very well; I do not want to be too long.

TWENTY-FOURTH DAY

Wednesday, 26th June 1907.

PRESENT:

The Right Hon. the Viscount SELBY (*Chairman*).

Colonel The Right Hon. A. M. LOCKWOOD, C.V.O., M.P.
Sir W. S. CHURCH, Bart., K.C.B., M.D.
Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir J. McFADYEAN, M.B.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. A. J. RAM, K.C.
Mr. W. H. GASKELL, M.D., F.R.S.
Mr. J. TOMKINSON, M.P.
Mr. G. WILSON, LL.D., M.D.

Captain C. BIGHAM, C.M.G. (*Secretary*).

The Hon. STEPHEN COLERIDGE recalled; and further Examined.

The Hon. S. Coleridge.
26 June 1907.

10551. (*Chairman.*) You are going to continue your charges against the Home Office?—Yes, my Lord. I have taken the opportunity, in deference to your Lordship's request, and I have endeavoured to shorten the material which I have to present to you for the remaining charges as much as I can. I have maintained the general order, but I have reduced it a good deal, so that it will not take very long. Just before I begin on them I should like to allude to one or two things which occurred on the last occasion. Your Lordship asked me first of all where the quotation from Dr. Johnson came from. I have looked it up, and I find it comes from the "Idler," No. 17, and there is another piece of the sentence before it which I should like to read; I had forgotten it, but I think it is very much *ad rem*. He says: "The *Idlers* that sport only with inanimate nature may claim some indulgence; if they are useless, they are still innocent; but there are others, whom I know not how to mention without more emotion than my love of quiet willingly admits. Among the inferior professors of medical knowledge is a race of wretches whose lives are only varied by varieties of cruelty; whose favourite amusement is to nail dogs to tables and open them alive; to try how long life may be continued in various degrees of mutilation, or with the excision or laceration of the vital parts; to examine whether burning irons are felt more acutely by the bone or tendon; and whether the more lasting agonies are produced by poison forced into the mouth, or injected into the veins. It is not without reluctance that I offend the sensibility of the tender mind with images like these. If such cruelties were not practised it were to be desired that they should not be conceived; but, since they are published every day with ostentation, let me be allowed once to mention them, since I mention them with abhorrence. *Mead* has invidiously remarked of *Woodward* that he gathered shells and stones, and would pass for a philosopher. With pretensions much less reasonable the anatomical novice tears out the living bowels of an animal and styles himself physician, prepares himself by familiar cruelty for that profession which he is to exercise upon the tender and the helpless, upon feeble bodies and broken minds, and by which he has opportunities to extend his arts of torture, and continue those experiments upon infancy and age, which he has hitherto tried upon cats and dogs." Then it goes on with what I read before.

10552. That leaves no doubt about Dr. Johnson's views in his day?—Yes, I thought you would like it. He is a man of very high character. Of course, that has all to do with vivisection without anæsthetics. I wish to say now that I have brought here the letters from the eminent surgeons whom I quoted, and I find on looking at them that I quoted in full all the short ones, and that I did not quote altogether in full the longer ones; but I have them all here, and I will read them to the Commission if they like to hear them all.

10553. It seems a pity to read them all over again; if you will read the omitted passages that will be enough?—I will read those of which I only published part. What I was reading from, I may say, was printed matter. I was reading from a reprint of my letter to the Home Office, which I found only embodied part of them. I did not know whether it did or not until I got them.

10554. I observe it was indicated in the print that there were parts left out?—Yes; I gave the shorthand writer what I had been reading from, and he put in the dots, no doubt.

10555. Perhaps you had better leave it if you have not got it handy. You will be asked some questions about it afterwards in cross-examination?—Very well. Then there was a mention of the Ferrier-Yeo case, and its similarity to the Cecil Shaw case, which was mentioned by Dr. Gaskell. I have looked it up, and I find that the similarity is very slight. I accepted Dr. Gaskell's suggestion that it was a parallel case; I said "yes," but I find I was wrong. I have taken the opportunity, since the last meeting, to refresh my memory by reading a report of the trial of Professor Ferrier—it is reported in the "British Medical Journal" of 19th November, 1881, pages 836 to 842, which I have here if anybody likes to look at it. I find that the two cases rest on by no means the same footing.

10556. I do not think this is really material. It was an incidental observation really. Whether it is parallel or not is not very material?—Only the innuendo conveyed is of importance to me. I do not mean to use the word innuendo in any offensive way, but the suggestion conveyed was that inasmuch as the Ferrier-Yeo case was a hopeless failure, and ended in the acquittal of the defendants, therefore it was a parallel case, and therefore if an action had been brought against Mr. Shaw a similar result would have ensued—that was the suggestion made to me.

10557. It does not seem to me to be material in this case. Whether the Home Office ought to have prosecuted in Dr. Shaw's case or not must be really independent of what happened a good many years before in the case against another surgeon even if it were a

parallel case. One does not mean when saying that a case is parallel to say that it is a *facsimile*. The Home Office must form their own judgment on the Shaw case, and they do not defend themselves on the ground that it was a decision in another case which hindered them from taking action?—I do not know what they did. If Dr. Gaskell will say that that was not his suggestion——

10558. I do not think it was meant in that way in the least?—It is very short; I only just want to point out the difference between the two cases. I wish to correct my own statement. I accepted Dr. Gaskell's suggestion to me that it was a parallel case. I find that it was not. It was before my time.

10559. It was only a suggestion; it was not an assertion that he had examined the case and found it to be parallel.

(*Dr. Gaskell.*) Not in the least.

(*Witness.*) I like to be quite accurate. If I accept a suggestion and find I am wrong I like to correct it. The Ferrier-Yeo case was a private prosecution brought by my Society, but before my time, and showed very clearly the difficulties under which a prosecution by a private society labours. My answer to Sir John McFadyean was that the Government officials should have prosecuted. The other difference is, that in the case of Professor Ferrier the charge rested entirely upon a newspaper report, a portion of which was dictated from memory by Dr. Roy, who subsequently stated in the witness box that the report was inaccurate. Professor Shaw, on the other hand, was the author of the paper, in which he described his own work: "My own work has consisted of," he said. "In the experimental research my aim was to discover. . . This rabbit I have kept alive. . . ," and he never suggested that the "British Medical Journal" had inaccurately printed his own paper. Therefore on those grounds I say the two cases were quite dissimilar. There is another point that I could not find at the moment, viz., the question and answer in the House on the 26th June, 1903, which deals with the number of experiments actually witnessed by the Inspectors during the whole year. I have got it now, and should just like to read it:—"Dr. Shipman (Northampton): To ask the Secretary of State for the Home Department how many experiments on animals under licence alone, and under Certificate B respectively, have been witnessed by an Inspector at any time during the experiment, and during the whole duration of the experiment."

10560. (*Sir Mackenzie Chalmers.*) What year was that?—The 26th June, 1903. The answer, by Mr. Secretary Akers Douglas, was: "During 1902 eleven experiments under licence alone were witnessed by the Inspector, and one under Certificate B. In the case of one (under licence) the whole experiment was witnessed; and with regard to the others the Inspector usually remained a considerable time, and on some occasions made more than one visit during the progress of the experiment. In the case of the one under Certificate B the Inspector also visited the animal next day. Inasmuch as the Inspector habitually visits without notice he cannot be sure of arriving at the beginning of an experiment so as to be able to see the whole of it, nor even of finding any experiment in progress. It may be added that the Inspector at his visits always sees any animals on which experiments may have been made, and carefully notes their condition." I want to say as regards this Certificate B, as I am on it, that down from November, 1892, to October, 1899, the words of the certificate as issued by the Home Office were "such animals being during the whole of the experiments under the influence of some anæsthetic of sufficient power to prevent their feeling pain." It is "during the whole of the experiment" down to 1899. In October, 1899, the words were changed to these: "Such animals being, during the whole of the initial operation of such experiments, under the influence of some anæsthetic of sufficient power to prevent their feeling pain." I became aware of this very vital change in the wording of the certificate, which seemed to me, and still seems, to admit of a great deal more pain being inflicted upon animals than the certificate in its former form; and I, therefore, wrote and asked the Home Secretary this question: "Whether conditions are invariably added to this certificate" (that is, Certificate B) "enforcing the employment of anæsthetics ensuring insensibility to pain from the commencement of the first operation until the conclusion of all manipulations of the animal, and until the last wound is closed aseptically?" That was my question. The object of that question is obvious. There are experiments, as I presume you are all aware, in which the animal is opened and various operations of an initial kind are done to it, after which it may be kept for hours in a condition of disembowelment during the period when observation of its condition takes place. What I wanted to know was whether during that period of observation the animal was lying disembowelled without any anæsthetic, under this certificate; therefore I asked that question, because after all the manipulation of the animal, if it was kept under anæsthetics during all that period of observation and until the last wound was closed again aseptically, it seemed to me that the certificate did preclude a great deal of torture which it otherwise would not. The answer is most illuminating. The answer was "Whenever the experiment would involve a series of cutting operations (which is very infrequent), conditions are added to the licence enforcing the employment of anæsthetics ensuring insensibility to pain during all operative procedures." That is the answer; and that answer to that plain question leaves me under the conviction, which I am sure the Commissioners ought to share, that that certificate admits of a very large amount of extreme pain and awful suffering, because under that certificate the animal may be kept disembowelled alive without anæsthetics as long as actual cutting operations are not being performed upon it.

10561. (*Chairman.*) Do you propose to show us any case in which that has happened?—My lord, I am dealing with the law.

10562. I know?—I am not on laboratories.

10563. You are a little too combative, I think?—I do not wish to be so.

10564. I merely asked the question in order to ascertain exactly how you apply that proposition, because you spoke of keeping the animal under anæsthetics first, while it continued lying on the table with its bowels open, and then in another place you added the words "until the wound has been aseptically closed," which is a long time afterwards, and possibly includes a time in which the suffering would be comparatively small. Those are two very different propositions. I wanted to know whether you were going to illustrate it by any particular case, because I quite see the force of it if it is not too widely applied?—I have not got the volume here now I am afraid; I thought I brought it.

10565. I daresay you will come to some other point when you can give an illustration?—Then I pass away from that for the moment. I wish to say a word now on the feeding of kittens with cow's milk, which was brought up on the last occasion. I daresay you will remember that my objection to that question was that in my opinion it was conceived in a spirit of raillery against those whom I represent. I perfectly unexpectedly found myself face to face with the suggestion here that the object of that experiment was to create disease in the animal by giving it diseased milk. I am right, am I not?

10566. (*Sir Mackenzie Chalmers.*) No. The point is that the man who wanted to perform the experiment wrote up to know whether it was necessary to take out a licence or not, because the object of his experiment was to try the effect of substituting the milk of another animal for mother's milk. He did not know what the effect would be, whether the mere substitution of different milk for the mother's milk would produce disease or not?—Whether weaning a kitten would do so! All kittens are weaned, surely, from their mother's and given cow's milk.

10567. I think they are generally suckled by their mother?—But there comes a time when they are weaned, like children are given the bottle.

10568. This was at an early stage to see what the effect of substituting other milk for cat's milk would be after the very earliest stage, and he was advised, at any rate, that it might produce deleterious effects on the kitten, and it would be safer for him to have a licence, just the same as with those fish feeding experiments. As you know, a licence is required in cases where fish are kept in a pool where there is effluent sewage, where if the water becomes contaminated the fish get ill and die. A licence has been granted for that, as you know.

10569. (*Chairman.*) I did not consider that the question was asked in a spirit of raillery. The case had

The Hon. S. Coleridge.

26 June 1907.

really come before the Home Office, on which they had to advise?—My point only is that as no suggestion of disease was made on both the former occasions when this cat was alluded to, I naturally was unaware that that was the object of his experiment. If the object of the experiment very likely included suffering to the kittens, it was, of course, a very proper case for having a certificate, and there is nothing more to be said about it.

10570. (*Sir Mackenzie Chalmers.*) There is just, perhaps, one point that I might clear up here. The witnesses for the anti-vivisection societies have taken up two lines. One line is this: that they object to experiments causing pain. Another line taken up has been that we have no right to exploit an animal, whether it causes pain or not, for the purpose of advancing human knowledge. Both those lines have been taken up before us?—I see. Of course, I cannot be responsible for other anti-vivisection societies.

10571. And this point, of course, was in my mind when I asked the question—that a great many experiments licensed by the Home Office, which appear as experiments, are absolutely painless in their results?—Then I pass from that. There was a question asked me by Sir William Collins: "Are the words of Certificate A mentioned in the question," referring to a question asked in the House of Commons—that is, whether Certificate B was mentioned as among the certificates dispensing with anæsthetics. I said "Yes, they were." I could not find it at the moment. I have got it now. Here it is: "Table 1. List of licensees who performed experiments under their licence upon animals. Experiments on cats and dogs without anæsthetics, E always coupled with A or B." I say that that is a general statement by the Home Office that Certificate B is for an experiment without anæsthetics.

10572. (*Sir William Collins.*) That is rather an answer to question 10328. Is it your suggestion that cases under Certificate B were classed among those dispensing with anæsthetics?—Yes, I have found it. They were classed under Experiments dispensing with anæsthetics up to 1897, at any rate. I have it here in the Table for 1897.

10573. (*Chairman.*) You have gone through the first five charges, and you said that there were seven, which I suggested might possibly be shortened?—Yes. I go on with my Charge VI. In this charge I charge the Home Office officials with having suppressed in the annual Parliamentary Return the names of those who take upon themselves the very grave responsibility of signing the certificates exempting licensees wholly or in part from the obligation to employ anæsthesia in their vivisections, although in the report of the former Royal Commission we find this clear direction: "We recommend that his (the Home Secretary's) advisers should be from time to time elected and nominated by himself; their names should be made known to the profession and the public." Now, my Lord, the Act of 1876 having provided that licences and certificates exempting licensees from the use of anæsthetics must be signed by persons holding certain official positions, if the Parliamentary Reports were drawn up in an open, straightforward manner they should give the names of these persons, so that anyone could ascertain who was responsible for exempting each individual vivisector from the obligation to use anæsthetics in his experiments, but it is quite impossible to discover from the report who assumes this very grave responsibility.

10574. What are the precise words of the Section as to what is to be reported?—Section 11: "Application for a licence under this Act."

10575. That names the persons who are entitled to give a certificate?—Yes.

10576. But is there anything about the reporting in the Statute; or is that only in the Order?—No, it is all "may," I think, all the way through; it is not "must."

10577. (*Sir Mackenzie Chalmers.*) "An application for a licence and certificate under this Act must be signed by one or more of the following persons"—that is to say, the President of the Royal College of Surgeons, and others?—Yes, but what his Lordship asked me was whether it must be put in the report.

10578. (*Chairman.*) You are complaining that in the report they do not report those facts?—Yes, that they do not give us the names of the persons who signed the certificates.

10579. Is that based upon what they ought to do for the convenience of the public, or upon what they ought to do if they are to obey the words of the Order?—It is what they ought to do if, as I say, there was no desire on the part of the Home Office to be partial or to screen the vivisectors from criticism.

10580. You do not put it upon any express words, but you put it upon the general duty which arises from the Order?—I also all through my evidence wish to rely very largely upon the recommendations made by the last Royal Commission, which sat before the passing of the present Act, and I say that that Report clearly contemplated the publication of the names of those who take upon themselves this grave responsibility. I pointed out this strange concealment of their names to several of those who may be assumed to be the persons concerned, and I asked them whether it was their desire that their individual names should thus be hidden under the cloak of an official title. Some of them, I think, have been manly enough to tell me that so far as they are concerned they have no objection whatever to the publication of their names; and others have told me that they consider it an insult to suggest that they wish to hide their names—which may or may not indicate that they would not object to their names being published. But whether any of them object or not, I am here to protest against the suppression of their names by the Home Office officials in a public document purporting to inform the public who sign these dreadful certificates. By the system of concealing their names under the description of their official positions, the Home Office officials themselves seem unable to know who the individuals really are who sign these certificates. In the Parliamentary report, dated the 8th June, 1899, I find Professor Schäfer's certificate (I take Professor Schäfer because he has been here), is stated to have been signed by the "Professor of Physiology, University College, London." That is the cloak under which the name is concealed. According to the Medical Directory for 1899, in that same year, the Professor of Physiology of University College was Professor Schäfer himself. The Home Secretary, therefore, was asked, by my request, in Parliament, "Whether the Home Office authorises or allows certificates to be signed by the operator himself on his own behalf?" and the reply was that such a thing "Would be directly contrary to the proviso in Section 11 of the Act." That answer is in Hansard of 24th June, 1899; I have it here if anybody wants to see it. I therefore wrote both to the Home Office and to Professor Schäfer himself to elucidate the truth, inquiring who the person was who is described in the Parliamentary report as "the Professor of Physiology, University College, London." The Home Office said (I have got the letter here), that this signatory was Sir John Burdon-Sanderson, who had resigned the Professorship of Physiology at University College, London, many years before. Professor Schäfer said—this is what he said to me—"I have not signed any certificates on my own behalf. The certificates I hold are signed by Lord Lister and Professor Halliburton only."

10581. (*Sir Mackenzie Chalmers.*) Is it licence or certificate?—"I have not signed any certificates on my own behalf" (he says. "The certificates I hold are signed by Lord Lister and Professor Halliburton only."

10582. Professor Burdon Sanderson, I imagine, signed the licence?—I do not know, I am talking about certificates now.

10583. (*Chairman.*) Was the answer of the Home Office an answer about certificates or a licence. You said that the Home Office referred to Sir John Burdon-Sanderson?—"Whether the Home Office authorises or allows certificates to be signed by the operator himself on his own behalf"—that was the question. I framed the question, so I know what it was.

10584. And the answer was what?—The answer was that it would be directly contrary to the Act if he did it. I then proceed, as I say, to ask Professor Schäfer himself, and he said that he did not do it. He said, "The certificates I hold are signed by Lord Lister and Professor Halliburton only," whereas the Home Office said it was signed by Sir John Burdon Sanderson.

10585. That is what I wanted to know. What does the Home Office say was signed by Sir John Burdon

Sanderson. What is the word they use in their letter?—We will get the letter.

10586. (*Sir Mackenzie Chalmers.*) May I read the letter, which your assistant has been kind enough to hand to me? "With reference to your communication of the 15th ultimo, enclosing a copy of Mr. Coleridge's letter of the 14th December last (which the Secretary of State regrets has not received a reply), I am instructed to say that in no case is an applicant for a licence under the Act 39 and 40 Vict., cap. 77, allowed to sign his own certificates, and Professor Schäfer has not done so. His licence was originally given on the recommendation of Dr. Burdon-Sanderson, by whom the certificate was signed, and who was at the time Professor of Physiology at University College, London, which post Professor Schäfer now holds. I am to add that the laboratories of the Mason University College, Birmingham, are not registered for the performance of experiments under the Act." That is neither here nor there?—I say that there is no inaccuracy in my statement which I make here. The Home Office said that Sir John Burdon-Sanderson signed the certificate.

10587. (*Chairman.*) Signed the licence?—Signed the licence and the certificate. I am not on the licence.

10588. I quite understand that; that is the reason I asked the question?——

10589. (*Dr. Gaskell.*) But not that certificate?—Yes.

10590. He signed the certificate at the time he signed the licence—that is years before?—But we have been already told that certificates expire every 12 months.

10591. (*Sir Mackenzie Chalmers.*) Perhaps it would be convenient once for all to state the practice. The practice is this: The licence has to be renewed every year, as you know. At the end of the year it comes up for consideration. It is originally signed by the people mentioned in the Act?—Is that so? They only recommend for a licence.

10592. Yes, they recommend for a licence. It does not go back to them. Every year the licence has to be renewed before the 28th of February. If the licence is not renewed the certificates fall with it. If the licence is renewed the certificates are also considered, and if they are not exhausted, that is to say, if the number of animals and experiments authorised by the certificate have not been exhausted, then it comes up for consideration whether that certificate should or should not be continued; it does not go back to the original people who gave the certificate, but comes up before the Home Office inspector at the Home Office for continuation. A licence, of course, may be renewed and the certificates not continued, or fresh certificates may be obtained?——

10593. The certificate necesarily falls if the licence falls; but they may or may not be continued if they are not exhausted?—But all that does not explain how it comes about that Professor Schäfer thinks the certificate was signed by one person, and the Home Office thinks that it was signed by another.

10594. (*Chairman.*) It is confusing, I agree, as appears from the different letters; but what I gather is that Sir John Burdon-Sanderson at the beginning recommended the licence and also recommended the certificate?—Signed the certificate.

10595. And also signed the certificate?—Yes.

10596. And that being started is referred to as being his signing the certificate in that letter?—Yes.

10597. But that subsequently the persons who are responsible for Professor Schafer's certificate at the time in question are Lord Lister and Professor Halliburton. That is what I should gather from it.

10598. (*Dr. Gaskell.*) Might I just ask what the date was when Sir John Burdon Sanderson signed that licence and certificate?—I have not got it. You must ask the Home Office. That is my point, that nobody can tell.

10599. All I meant was that if Sir John Burdon-Sanderson signed a certificate for a certain experiment it is very unlikely indeed that Professor Schäfer could be doing that same experiment many years after. He would probably have to get a new certificate?—The point, if I may say so, that I am making is my desire, and the public desire, the humane public, to know who signs certificates authorising vivisectors to do without anæsthetics, and when we come down to any particular case we find it almost impossible to find who that person is who takes that grave responsibility, and the confusion is accentuated by the Home Office saying that it is one person and the vivisector himself saying that it is another. That is my point. In this case there is no mistake about it. The Home Office said it was one person who vouched for Professor Schäfer's certificate in a particular year, and Professor Schäfer says it was two other gentlemen. This, therefore, I say, is a most informing example of the results arising from the use made by the Home Office officials in the Parliamentary Return of titular professorships as cloaks to hide the identity of the vivisectors who sign each other's certificates. Professor Schäfer's certificate is stated in the Report of 1899 to have been signed by "the Professor of Physiology, University College, London." The Medical Directory for that year told us that this person is Professor Schäfer himself. The Home Office assert that the person is Sir John Burdon-Sanderson, and Professor Schäfer says the person is not himself but Professor Halliburton. The task of reconciling these statements is quite beyond me. I say that the impossibility of tracing the identity of the persons responsible for signing certificates has been rendered absolute by the statement of the Home Secretary in the House, that all certificates expire on the 31st December. I understand now that they do not. My position about that is very clear. I say that here are these persons who sign these certificates. Many of them have told me themselves that they have no objection to their names being published. I have protested again and again to the Home Office against their names being concealed in this manner, and I protest again here against their names being thus concealed. If they have nothing to be ashamed of why are not their names published? It is a very grave responsibility that they take upon themselves in giving their brother vivisectors leave to vivisect without anæsthetics.

10600. (*Chairman.*) You attack these gentlemen very strongly?—I am not attacking these gentlemen; I am attacking the Home Office.

10601. You said, why do they wish their names to be kept out just now?—I do not say that they do. I did not mean that. I say, Why are their names kept out? Some, I say, have been manly enough to say that they do not wish to have their names kept back.

10602. I thought what you read certainly was a charge that these gentlemen themselves were extremely anxious to cloak up?—No, on the contrary, I have read what I wrote.

10603. I mean what you read just now?—I give in detail what they said to me in answer to my letter. Some said that they had no objection; others said it would be an insult to suggest that they wish to hide their names. Nevertheless, their names are hidden for them by the Home Office, and against that I protest. I pass on to the next charge. I am here to charge the Home Office officials with shielding the names of such licensees as they know to have broken the law, although the former report contains these words:—"Abuse of the power conferred by the licence must, of course, render the holder liable to its withdrawal, but this will involve great disgrace"—a phrase, in my opinion, which clearly indicates that the framers of that report contemplated the publication of offenders names, for no great disgrace can possibly appertain to a secret remonstrance or a secret withdrawal of a licence. Under Section 11 of the Act, 39 and 40 Vict. c. 77, a person who performs experiments calculated to give pain without a licence in contravention of the Act is "guilty of an offence against this Act," and shall be liable to a penalty not exceeding £50 for a first offence, and for a second to a penalty not exceeding £100, or to imprisonment not exceeding three months. Anybody who commits an offence against any other Act of Parliament which creates a criminal offence, and who confesses himself guilty of the offence, would in the ordinary course be brought before the Courts and subjected to sentence. The Home Office officials, however, have never instituted proceedings against any vivisector for committing admitted offences against the Act, not even in a case described by themselves as a "case of deliberate violation of the Act after warning."

10604. (*Colonel Lockwood.*) What was that case?—That you will find at Question 38. I do not know to this day what the case was; the case has never been revealed to us, not even before the Commissioners. Mr. Byrne said: "This power has been exercised on four occasions," and at the end of that answer you will see "He had been previously warned as to the necessity

The Hon. S. Coleridge.

26 June 1907.

for certificates B and EE in such cases. It was considered by the Secretary of State to be a case of deliberate violation of the Act after warning, and his licence was revoked." That was all it amounted to.

10605. (*Sir Mackenzie Chalmers.*) Would you just give the facts first. A licensee who did not hold certificates B and E E performed the operation of gastric fistula on a cat under anæsthetics, the animal being allowed to recover. That was the case?—Yes, a breach of the Act—a clear breach of the law.

10606. And his licence was revoked?—Yes, his licence was revoked. But that fact—the fact of his licence being revoked, and the licensee's name were never mentioned even in the annual report. And, further, instead of prosecuting and punishing him, he was quickly reinstated as before, this very man, though we still do not know his name.

10607. (*Chairman.*) And you say that his name ought to have been mentioned in the report?—Certainly.

10608. And he ought to have been prosecuted?—Certainly.

10609. (*Colonel Lockwood.*) There is a footnote, you see, to that evidence?—He was not only not prosecuted, he was reinstated; after just a decent interval of a month or two he was put back where he was, as if nothing had happened. "Mr. Byrne subsequently wrote that a few months later the gentleman in question was allowed a fresh licence and Certificate A for inoculations, after special inquiry, on his representation that the revocation of this licence had stopped a very valuable investigation." We are not told what the "very valuable investigation" was. To this day the public cannot discover the name of that offender. Proceeding a little further, I tried to see if I could get it from the Home Office by writing to them. In the House of Commons, I may say—this is in Hansard of the 26th June, 1903, page 629—the Secretary of State said: "Wherever the conditions of the licence were violated the severest notice was taken of it, and, if necessary, the licence was revoked." I wrote and asked "what were the instances of violation of the conditions of the licence to which you alluded in your speech above quoted, of which the severest notice was taken?" I wanted to know who they were. The reply was: "The Secretary of State does not think that any useful purpose would be served by the publication of the names of these experimenters." I just wrote that letter to test it, to see whether they would continue to shelter the names of the peccant vivisectors, and they did.

10610. (*Sir Mackenzie Chalmers.*) There is one preliminary point that I should like to clear up. If you write to the Home Office it is only a matter of courtesy that they answer you?—Yes. I do not complain of any lack of courtesy on any occasion from the Home Office.

10611. The only place in which the Home Secretary is answerable is in Parliament?—Yes.

10612. As a matter of courtesy, they answer your letters, but if the Home Office undertook to give explanations to every one of the 35,000,000 people in England who write to them about any of their business it would be a little more than they could do?—But without undue egotism I may say that I do not regard myself as writing to the Home Office on any of these occasions in my own individual capacity. I have never written to them in any other capacity than as honorary secretary of a great and important society. I quite admit that in my own individual capacity I would have no claim.

10613. I do not know of any difference between a great and important society and any single individual who asks a question?—I only say for myself that I should not write except as the representative of what I consider more important persons than myself.

10614. (*Chairman.*) Does that conclude that charge?—Yes. I come now to my eighth charge. I am here to charge the Home Office officials with preparing for the Home Secretary evasive and insufficient replies in the House of Commons to plain questions on the administration of the Act, and with making evasive and insufficient replies themselves in official correspondence with my Society, and with leaving perfectly proper questions unanswered altogether. I accept Sir Mackenzie Chalmers' dictum that they are not obliged to answer any question at all, of course; but at the same time I think that on a question of the administration of the Act they would naturally answer reasonable questions, and I think they generally do.

10615. (*Sir Mackenzie Chalmers.*) You can take it for granted that they will always make inquiry. They would not necessarily tell you the result of that inquiry?—That is rather my complaint. Mr. Paulton, on the 24th July, 1899, asked "Whether Dr. Poore, while holding the office of Inspector, had signed certificates in his capacity of Professor of Medical Jurisprudence, University College, London"; the answer of Sir Matthew White-Ridley was "The answer is in the negative." I am assuming, of course, that these answers are prepared by the permanent officials. Colonel Lockwood asked: "Does Professor Poore sign the certificates?" to which Sir Matthew White-Ridley replied: "I am informed that it is not the case that he does so." Then Mr. Paulton asked: "Then how is it that the statement appears in the Report of the Inspector? Will the right honourable gentleman further inquire as to its accuracy?" and Sir Matthew White-Ridley replied: "Yes. I was only aware five minutes ago that the Report seemed to indicate this, and, of course, I have not had time to inquire." Now, the certificates signed by Dr. Poore were still in force while he was Inspector, and the official who prepared Sir Matthew White-Ridley's answer must have known it; they must have known that these certificates signed by Dr. Poore were in force at the time the question was asked.

10616. (*Chairman.*) Would you read the question again?—The question is "Whether Dr. Poore, while holding the office of Inspector, had signed certificates in his capacity of Professor of Medical Jurisprudence, University College, London"; and the answer is in the negative. I quite agree that it is perfectly accurate, but I venture to say that it is extremely evasive. The Home Office officials knew perfectly well that these certificates had been signed by Dr. Poore before he was Inspector, but in my opinion it was a strange thing that they should not have added to the answer "Yes, they were signed by Dr. Poore, but not while he held the office of Inspector."

10617. (*Sir John McFadyean.*) Might I ask why that question was not put in a form which would have made evasion impossible? Why was not the question, whether the certificate which was signed by Dr. Poore before he took office was still in force?—Because we did not know it. According to the documents before us, it appeared that he had signed certificates while he was Inspector, because we had at that time the statement of the Home Office that certificates expired on the 31st December. Until this explanation of Sir Mackenzie we had always believed that that was so. Therefore it seemed impossible that Dr. Poore had not signed them while he was Inspector, because there was his name on them, and apparently he was the person. It transpired that he had signed them many years before, and instead of expiring on the 31st December they have been kept alive nominally, Sir Mackenzie Chalmers now tells us.

10618. (*Chairman.*) You say that the replies of the Home Office are evasive. What had the Home Office to conceal in that case? What were they evading? It seems to have been perfectly regular?—No, they did not tell the public the truth.

10619. Evasive, you say, and, apparently, from the way you put it, wilfully evasive answers?—Yes, wilfully evasive.

10620. Therefore they were going to evade something?—Yes.

10621. What was it they were trying to evade, because if they had said all that you say they should have said, nothing could have been said against them?—Yes, I think the public would have been very much surprised and indignant at discovering that a vivisector held a certificate exempting him from the use of anæsthetics, signed by the very man who was to inspect him to see what was done.

10622. No, signed by a man before he was Inspector at all?—But still responsible. The certificate was alive.

10623. The certificate being there, it was alive by virtue of the Act of Parliament?—Yes, quite so, and in my opinion a very improper thing.

10624. You may amend the Act, but I cannot see what the Home Office have got to evade?—The Home Office have themselves said that the person who is Inspector ought not, under the Act, to sign certificates.

10625. And Dr. Poore did not do that?—But the certificate was kept in force after he was Inspector.

10626. That is a totally different thing?—No, I do not see it. I think he was a most improper signatory.

10627. When you say that you do not see that it is a different thing you startle me?—I do not. If it is kept alive every year, it is the same thing as his signing it every year again. That is my opinion, and I think it ought to be the opinion of everybody.

10628. (*Sir John McFadyean.*) The Government have not admitted your view of the question, have they?—What view?

10629. The view you have just been putting forward, that it is improper to allow a certificate to continue because it was signed by the Inspector before he took office?—The Government have said that it is not proper for a man to sign his own certificate.

10630. That is not the question. They have not admitted your view?—Oh, dear, no.

10631. Therefore it hardly seems fair to charge them with evasion; because the charge of evasion seems to imply that your view was necessarily the right one?—I say my view is the view that the general public would take; I am quite convinced of that. That is my charge, and I am quite convinced that the general public would take the view that it is very improper for the Inspector to sign the certificates of the very vivisectors he had to inspect. I am quite convinced of that, and I should have thought the Commission would have been so, too.

10632. (*Chairman.*) Your conviction does not necessarily govern ours?—No, my Lord. I invite you to share it; I can do no more.

10633. (*Sir Mackenzie Chalmers.*) Mr. Coleridge's point, as I understand it, is this: that when a gentleman who has signed certificates or signed recommendations for a licence becomes an Inspector, all licences and certificates signed by him ought, *ipso facto*, to expire?—You have incorporated the licences into it. I have not said anything about the licence. I am entirely upon the question of certificates exempting men from using anæsthetics. With that alteration I accept that statement as my view.

10634. (*Sir William Collins.*) Is your point that Dr. Poore, as a matter of fact, was inspecting work that was being done as the result of certificates given under his own hand?—That is my point, and I think that is very improper. Then, this is not a very important matter, but I should just like to allude to it. I called the attention of the Home Office to Clause 9 of the Act, which provides the machinery whereby results may be collected and subsequently incorporated in the yearly report; and I said that my committee hoped "that the public may, in the next report, be told what results in the way of benefit to mankind and the healing art have been achieved by all the torture that is continually being inflicted upon animals in the ever increasing laboratories of this country?" I asked that very plain question. We are always being told that such wonderful results are being achieved by vivisection, and I asked the Home Office whether, under Clause 9, they would not let the public into the secret and let us have some of the results published in the report.

10635. (*Chairman.*) When was that?—That I wrote on the 8th of December, 1898. The answer was that it would have attention, but nothing further ever happened; the results have never been published in any report. It is not a very important matter, but in passing I should just like to point it out. Now, on the 15th July, 1904, in Hansard I find Dr. Shipman asked the Secretary of State for the Home Department "whether he can state in how many cases the licensed vivisector himself has been the only authority present at the operation whose duty it is to see that anæsthetics of sufficient power to prevent the animal feeling pain are administered?" The answer by Mr. Secretary Akers Douglas was: "I have no information enabling me to answer this question." Surely the Home Office know at how many experiments the Inspector had been present, and consequently, at how many the vivisector himself was obviously, the only authority alluded to in this question; and therefore I think that that is beyond all question an inadequate answer. On the 22nd July, 1904, Dr. Shipman again asked the Secretary of State for the Home Department "How many dogs were vivisected in University College during the year 1903"—a very plain question. The answer is: "As I informed the honourable Member on the 4th of May last, I have no material from which I can answer this question." No material! Therefore if he does not know how many dogs are vivisected in a particular laboratory, he must know nothing at all about what goes on there. The first thing he must know, if he knows anything about it, is the number of dogs vivisected there. It is no doubt a perfectly true reply, but it seems to me that he was in a position to get, and ought to have got the information before replying. He could have found out by inquiring. I presume they keep records there—they ought to do so—of how many dogs they use.

[*The Hon. S. Coleridge.*
26 June 1907.

10636. (*Sir Mackenzie Chalmers.*) There would be no return under the licence, would there? As long as the animal is put under anæsthesia and killed before it recovers from the anæsthesia, it would come in under the licence. There is nothing in the licence to limit the number of animals that can be experimented on in that way?—That I do not know. You issue the licences. I have no idea what powers are given to the vivisectors.

10637. That is the Act itself?—I do not know.

10638. (*Mr. Tomkinson.*) Did that question apply to the number of dogs vivisected during that year?—During 1903, the year before. I asked for the year before. Now, on the 15th of July, 1904, Dr. Shipman asked the Secretary of State for the Home Department "How many experiments under the Act 39 and 40 Vict., cap. 77 have been performed at each place on the register during 1903, and whether he can ascertain how many separate experiments were performed on the same animal during the same period." Here, again, the answer is that there is no material upon which he can give any information. Of course, if he had answered this question he would have known about the brown dog having several wounds in it; but he did not. We know that he did not know anything about that brown dog. I maintain that he ought to have known. I think the Home Office ought to know what happens to every dog that is vivisected. If they have not the machinery at their own command to know, they ought long ago to have asked Parliament to give them that machinery in my opinion, if they care at all to protect the animals from unfair treatment. Then I asked this—and I must say I do think this is a case of evasion: On the 6th October, 1904, I wrote, "I desire very respectfully to inquire whether you yourself, or whether your predecessors in the office of Secretary of State have required from the licensees under the Act any guarantees of their humanity, and if so, what is and has been the nature of these guarantees?" The reply was: "I am directed by the Secretary of State to say that he has no doubt that you are acquainted with the duties imposed upon him" (that is, the Home Secretary) "by the Vivisection Act, and that he has every reason to believe that these duties are duly and faithfully performed by the Home Office." I think that letter is interesting, because it answers a great deal of what Sir Mackenzie Chalmers said about the devolution, and what I wish to say about the devolution of responsibility. Here, over the signature of Henry Cunynghame, we have a statement of the duties that are imposed upon the Home Secretary by the Vivisection Act, and that they are duly and faithfully performed, not by him, but by the Home Office. So that there in that letter the Home Office duly takes upon itself the responsibility for fulfilling the duties put upon the Home Secretary by this Act.

10639. (*Sir Mackenzie Chalmers.*) Does Mr. Coleridge expect the Home Secretary to perform the functions of Inspector?—Of course not. That is what I say. That is my contention. That the Home Office officials are the real persons against whom I bring my indictment. I call that a clear evasion. Because, of course, I know the duties imposed upon him, and I know perfectly well that the Act does not impose the duty in its provisions, but the whole tenour of the Act does, in my opinion. I then wrote: "A large discretion was left by that Act in the hands of the Home Secretary personally, a discretion which I take leave to believe was intended by Parliament so to be exercised as to provide guarantees of the personal humanity of each

The Hon. S. Coleridge.

26 June 1907.

individual licensee. The question that I, therefore, desire most respectfully to put to you is: do you require of each vivisector a guarantee of his personal humanity before granting him a licence or passing his certificates? I put this question" (I say) "as representing a very large number of serious persons to whom your anwer is of grave importance in view of future legislation in the matter." I was then drafting my Bill. Again I received a second evasion. "I have laid before the Secretary of State your further letter of the 27th ultimo, and he directed me to inform you in reply . . . . that if any instance of inhumanity on the part of a licensee is brought to his notice, he will be prepared to act promptly in the matter." That is the answer which I say is an evasion. I replied: "I have received the letter of the 12th of November, written by your direction, informing me that if any instance of inhumanity on the part of a licensee is brought to your notice you will act promptly in the matter. In view, however, of the fact that you have yourself stated that during 1902 only one experiment upon a living animal out of a total of 14,906 was witnessed throughout by either of your Inspectors, the contingency of which you now speak may be regarded as remote. But I beg leave to point out that I did not ask whether you would act promptly in that remote contingency, and I fear I have failed to make my inquiry intelligible. I will, therefore, very respectfully repeat it as plainly as I can." I then repeat the question: "Do you require of each person licensed under the Act 39 and 40 Vict. c. 77 any guarantee of his personal humanity before granting him a licence or passing his certificates?"—a very plain question. And at last the Home Secretary, or rather the Home Office, takes refuge in silence. "I am directed by the Secretary of State to say that he has nothing to add to his previous letter." They will not answer the question—a masterly silence. I suggest that if he did require the guarantees of vivisectors of their humanity he would have said so, and certainly would not have evaded the question and refused to answer it. I therefore must come to the conclusion that he does not require such guarantees; but though he does not require them he does not like to admit it in a letter that may be published. Therefore I say that in my opinion the Home Office evince more solicitude for the vivisectors and for the Home Office than for the animals under their charge. I will not go into this story of the brown dog and Certificate B, except to say (I do not want to go into it all again) that in my opinion as the two operations performed by Dr. Starling upon that brown dog were admittedly done under Certificate B, and as the words of the certificate tell him that he is to destroy the dog immediately the object of the experiment has been obtained—and it was obtained by the second operation—I think he did an illegal act in handing it over to Mr. Bayliss. It was his business to see it killed, and in my opinion the Act gives the animal a vested right to be destroyed painlessly as soon as the object has been attained of the experiment under Certificate B.

10640. (*Chairman.*) Does that conclude that charge?—Yes. I pass to Charge IX., which is a very simple one; it is self-evident from the yearly Returns. I am here to charge the Home Office officials with putting forward annually a Parliamentary Return in which it is asserted, on the official authority of the Government Department, that not a single experiment in thousands inflicted on animals in Great Britain with its permission can be specified as entailing any pain at all, when all the while this plausible assertion is based upon no better evidence than the bare assertion of the vivisectors themselves, who are not expected to report themselves as cruel men.

10641. (*Sir Mackenzie Chalmers.*) The form of the Report has been altered since then?—Yes, down to a certain date the form of the return was "Return showing number of experiments performed on living animals during the year 1903 under licences granted under the Act 39 and 40 Vict. cap. 77, distinguishing painless from painful experiments." If this paper is supposed to distinguish between painful and painless experiments and you can find inside it no single experiment specified as painful, that is a statement to the public that there are none painful.

10642. When was that form abandoned?—Quite recently, I think.

10643. (*Mr. Tomkinson.*) That is an annual return?—Yes.

10644. It has not to be moved for?—I think somebody asks for it. Colonel Lockwood would know that.

10645. (*Colonel Lockwood.*) I think it is laid before the House in the ordinary course; nobody asks for it.

(*Chairman.*) It is laid on the table by the Department?

(*Sir Mackenzie Chalmers.*) Yes.

(*Witness.*) There generally is a question asked, because I suppose somebody wants to know.

(*Colonel Lockwood.*) Yes, somebody is keen about it.

(*Sir Mackenzie Chalmers.*) It is only a question about the date.

(*Witness.*) Charge X. is the next one. I charge the Home Office officials with placing a certain vivisector year after year beyond the reach of the safeguard erected by the Act to protect animals from illegal treatment by licensees, by giving him permission to vivisect in private places, thereby placing him beyond the possibility of legal inspection, because Clause 10 of the Act of 1876 gives the Inspector no right of entry into or inspection of any unregistered place. I am alluding here to Sir Victor Horsley, and there is no denying it. Mr. Byrne, in answer to Question No. 73, says "There were a few cases in which, on account of scientific eminence, or the high position of certain licensees, they were allowed to perform their experiments in unregistered places." High position! High position the former Royal Commission informed us was no guarantee of humanity. They said that persons in very high positions it could not be denied had shown gross inhumanity. Having discovered myself that Sir Victor Horsley could perform experiments where he liked, I wrote to the Home Secretary on the 25th of July, 1905, and I said: "On page 27 there is a note" (I was then alluding to the yearly report) "which runs thus: 'Sir Victor Horsley could also perform experiments at such places as might be necessary for the purpose of his experiments.' You (the Home Secretary) have, therefore, authorised this vivisector to perform his experiments anywhere he likes, and have thereby placed him beyond the possibility of legal inspection, for in Clause 10 of the Act the Inspectors' right to inspect at all is limited to registered places. May I ask whether you have not in this case deprived the animals vivisected by Sir V. Horsley of every safeguard provided by the Act, and whether by so doing you have not shown yourself unmindful of the sacred interests of those pitiful creatures committed to your charge by the law, who are the living victims of experiments? Whatever be your answer to these questions, I take leave to enter my solemn protest, in the name of many thousands of thoughtful and humane people, against this safeguarding of a vivisector from all inspection. The law constitutes you the protector of vivisected animals, and you have made yourself the guardian of the vivisector!" That protest I sent to the Home Office on the 24th of July, 1905, and no notice whatever was taken of it.

10646. (*Chairman.*) You sent it to the Home Secretary?—I sent it straight to the Home Secretary.

10647. That was Mr. Akers Douglas?—Yes, I think it was some new Home Secretary I addressed, because I hoped to get more from the new Home Secretary than the last. I expect it was soon after a reappointment. In spite of that protest of mine, which is very plain and clear, Sir Victor Horsley's permission to vivisect where he likes remained.

10648. Was it a specific permission given to him in writing, or was it a licence or certificate of any kind. How was it done?—I do not know. That is a question Sir Mackenzie must answer. It is simply a note at the foot of the return. He has had it for years I believe. I had not noticed it.

10649. I understand that it was probably endorsed on his licence?—I really do not know.

10650. (*Sir Mackenzie Chalmers.*) You do not know as a fact whether he made use of it or not. He asked for it for a special purpose?—I do not know. I am not attacking Sir Victor Horsley. I am attacking the Home Office for giving him permission. Whether he uses it or not is a matter of indifference to me on this charge. I am charging the Home Office with permitting this gentleman to vivisect outside the Act and beyond the reach of inspection.

10651. (*Sir John MacFadyean.*) Is it your charge that under no circumstances should it be permitted to

be done?—Certainly. No vivisector should be placed beyond the reach of inspection, because the whole Act of 1876 definitely in its provisions implies that every vivisector is to be inspected, otherwise it would not have provided inspectors. And if vivisectors are to be inspected, why is one to be given *carte blanche*.

10652. But might the vivisector not signify his entire readiness to be inspected in an unregistered place? Would that make any difference to your position?—It certainly would. You clearly understand that I am not making any attack upon Sir Victor Horsley.

10653. (*Chairman.*) Is there any special power in the Act given to the Home Office to permit this?—Yes, no doubt it is legal; it is all "may" in the Act. I do not think there is anything compulsory.

10654. For cases done on farms, for instance?—Yes, I am not suggesting that it is outside the Act at all. But what is illuminating is, that though this leave was given to Sir Victor Horsley for many years, and was maintained for many years, and was maintained in spite of my protest in July, 1905, I find that it was withdrawn on the 13th of February, 1906, just a month before the announcement of the Royal Commission in the newspapers, just at the time when we may assume that the Home Office were perfectly well aware that there was going to be a Royal Commission; and it is a very remarkable thing that contemporaneously with the knowledge in the Home Office that there would be a Royal Commission, this leave was withdrawn from Sir Victor Horsley to vivisect where he liked and beyond the reach of inspection.

10655. (*Sir John McFadyean.*) But have they withdrawn all similar leave to other vivisectors?—I should think probably not. There are some, I think, who have to do with inspecting grouse on a moor. I should have no objection to that.

10656. It was a question of the motive which inspired the Government—your reason for attributing this motive to the Government. If they had been in such a fright, would they not have withdrawn the whole of these permissions?—No, I should think not. If it be so—you are putting it into my mouth (I do not know whether they have or have not withdrawn them all)—if they have not withdrawn the others and have withdrawn the one to Sir Victor Horsley, the assumption is that the one to Sir Victor Horsley is less defensible than the others, in the public eye. That is the conclusion I should come to. That finishes charge X. Now I have dealt with Charge XI. under another heading, but I wish to enforce this charge: that although the officials of the Home Office must be aware that the Report of the Royal Commission in 1876 contained this pregnant warning on page xvii.: "It is not to be doubted that inhumanity may be found in persons of very high position as physiologists." They apparently have made no inquiries, public or private, into the vital question of the character for humanity of the licensees to whom they have delivered over the animals to be vivisected, and that although the Act of 1876 placed upon the Home Secretary the tremendous responsibility of personally protecting animals from inhumanity. I have already cited this correspondence as showing the evasive replies given by the Home Office to proper questions. I now cite it to show that we must conclude that as a fact no guarantees of humanity are required by the Home Office. I think it is quite clear that that is so, and in addition to the Home Office correspondence, which ends with a frank refusal to continue the correspondence without giving me that information, we have the following question put to Mr. Thane at Question No. 400: "Do you inquire at all into his"—that is, the experimenter's—"reputation for humanity or the reverse or anything of that kind?" To which he replied: "No, I do not inquire about humanity." On the point of the question of the humanity of vivisectors, I wish to draw the attention of the Commission to the evidence given before the former Royal Commission by Dr. Klein.

10657. (*Chairman.*) Have you finished your charges against the Home Office?—No, it is part of this charge—I cover it under this charge. There is one more charge after this, and only one more. It begins at Question 3538: "(Q.) What is your own practice with regard to the use of anæsthetics in experiments that are otherwise painful? (A.) Except for teaching purposes, for demonstration, I never use anæsthetics where it is not necessary for convenience. If I demonstrate, I use anæsthetics. If I do experiments for my inquiries in pathological research, except for convenience sake, as, for instance, on dogs and cats, I do not use them. On frogs and the lower animals I never use them. (Q.) When you say that you only use them for convenience sake, do you mean that you have no regard at all to the sufferings of the animals? (A.) No regard at all. (Q.) You are prepared to establish that as a principle which you approve? (A.) I think that with regard to an experimenter, a man who conducts special research, and performs an experiment, he has no time, so to speak, for thinking what will the animal feel or suffer. His only purpose is to perform the experiment, to learn as much from it as possible, and to do it as quickly as possible. (Q.) Then for your own purposes you disregard entirely the question of the suffering of the animal in performing a painful experiment? (A.) I do. (Q.) Why do you regard it then when it is for a demonstration? (A.) Because I know that there is a great deal of feeling against it in this country, and when it is not necessary, one should not perhaps act against the opinion or the belief of certain individuals of the auditorium. One must take regard of the feelings and opinions of those people before whom one does the experiment. (Q.) Then am I wrong in attributing to you that you separate yourself entirely from the feeling which you observe to prevail in this country in regard to humanity to animals? (A.) I separate myself as an investigator from myself as a teacher. (Q.) But in regard to your proceedings as an investigator, you are prepared to acknowledge that you hold as entirely indifferent the sufferings of the animal which is subjected to your investigation? (A.) Yes." Now, further down, at Question 3641, you find this: "(Q.) When you take hold of an animal for this purpose, what is done with it; do you bind it up while you are making this injection? (A.) If it is a large vigorous animal, as a dog, we do bind it and fasten it. A cat we generally must chloroform. (Q.) Why do you not chloroform a dog? (A.) We chloroform a cat because we are afraid of being scratched. (Q.) Why not a dog? (A.) If it is a small dog there is no fear of being bitten by the dog." That is the evidence which was laid before the former Royal Commission by Dr. Klein. It was laid before the Commission on a certain Thursday, the 28th of October, 1875. On October the 30th of the same year, three days later, Professor Huxley, who was a member of that Commission, wrote to the great Darwin, and this is what he wrote ——

10658. What is this on? Are we to have the Commission of 1876 brought up?—I am going to bring it right up to date. Dr. Klein has a licence at this moment.

10659. That may be; but we are on the question whether the law requires amending?—This is a charge against the Home Office of continuing a licence to a man whose inhumanity is patent.

10660. Then let us deal with that?—I want to show what Professor Huxley thought of this man.

10661. What Professor Huxley thought of Dr. Klein cannot matter?—But he was on the Commission.

10662. That may be. It is thirty years ago, and the law has been entirely altered since. The law now prevents these things. By all means state that Dr. Klein has a certificate still, and that you think that is an improper thing, as I understand; but we really cannot go through the whole of this?—It is not very long; it is a very short letter from Professor Huxley.

10663. The evidence runs very long. I think at any rate there is more recent matter and more material matter which takes up so much time that I think we can dispense with the history of what happened before this Act, which is, of course, the Act we are discussing?—My Lord, I maintain very respectfully that it is very much *ad rem* what a Commissioner thought of Dr. Klein at the last Commission, in consideration of the fact that Dr. Klein has for years had a licence and certificate from the Home Office, and has one now, on the point that they are perfectly regardless of the humanity of the vivisectors, and take no interest in it.

10664. You have read Dr. Klein's own statement. I object to time being taken up by having cited to us what this, that, or the other person, whether a member of the Commission or not, thought of what Dr. Klein said. We have Dr. Klein's evidence, and the only point that is material so far as I understand, is that you complain of Dr. Klein having a certificate?—Well, my Lord, I think this has been already dealt with before this Commission.

The Hon. S. Coleridge.

26 June 1907.

10665. Yes, and that is another reason why we should not go into it; we have had this read to us before?—It is a very short letter, my Lord.

10666. (*Mr. Tomkinson.*) I suppose that Dr. Klein has not a certificate to experiment in his own laboratory, like Sir Victor Horsley?—No, I believe his certificate is for the Brown Institution. I think there has been a point made before this Commission that Dr. Klein altered his evidence.

10667. (*Chairman.*) That may be?—Then I think it is material, my Lord.

10668. But the alteration of the evidence was before the other Commission?—Yes, but you have had it dealt with here.

10669. You have cited what he said about his practice. If you wish to qualify that in any way or to increase the force of it by a statement which he himself made subsequently, by all means do it?—You see, my Lord, the point has been made here that Dr. Klein altered his evidence, and it is on that ground that I wish to lay this letter before the Commission, as showing what Professor Huxley, one of the Commissioners at the time, thought of that evidence.

10670. But that Commission is not this Commission, and there is no end to that sort of evidence of what other people thought about Dr. Klein. We have Dr. Klein's statement, which you say stamps him as being an inhuman vivisector, and you say that he ought not to have had a licence given him?—I say that he ought not to have one now.

10671. But when it comes to citing other people's opinions to prove that Dr. Klein was an inhuman person, there is no end to it?—Well, my Lord, I submit that I am entitled to read this letter. I request to be allowed to read it. If I am refused I pass on.

10672. I think we ought not to have it. It is admitting a great deal of matter which is not relevant?—Then I pass from it.

10673. You say that Dr. Klein has had a certificate which he ought not to have had?—He has it now so far as I know. He had it in the last yearly report, and he has had it ever since 1884, I think. Then I wish to show, if I may, by citing a short passage out of an article by C. S. Myers, who is a man of great distinction at Gonville and Caius College, Cambridge, a first class man in both parts of the Natural Science Tripos, and the author of various articles in scientific journals, that the opinion of Dr. Klein, in which he said that he had no regard for the feelings of animals, did not expire in the year 1876, but is held by persons of distinction to this day. I do not know whether I may read it for that purpose. It is an article from a man of great scientific eminence, who writes quite recently to say that he endorses Professor Klein's opinion.

10674. I cannot see how that is relevant?—Very well. This is only to bring it up to date, so that it shall not be said that it is thirty years old. It is an article up to date endorsing those views that the sufferings of animals are of no account.

10675. There are a number of people over Europe, as we know, who hold those views?—He is an Englishman and a Professor at Cambridge at the present day. I come to my last charge. I am here to charge the Home Office officials with having placed themselves in improper private confidential relations with a private society composed of supporters of vivisection entitled to no more consideration than the National Society composed of opponents of vivisection. Mr. Byrne was asked at Question 27: "The Association for the Advancement of Medicine by Research is a body consisting of a great number of eminent surgeons, I suppose?" and he replies, "Yes, I believe it includes, nominally, at any rate, a large number of gentlemen of great distinction in this matter of investigation"—I suppose by investigation he means vivisection—"but no doubt the Commission will ascertain its precise composition from the body itself." Then we have had the assurance on several occasions, and we had it from Mr. Akers Douglas in 1903 that: "No licence or certificate was granted except on the recommendation of an eminent medical man, such as the President of the College of Physicians or the President of the College of Surgeons, or without reference to the Society for the Propagation of Scientific Research"; that is what he called it, it is a better name for it, almost, I think, than its real one. Then we have Mr. Byrne, who tells us that it is a purely voluntary organisation. He is asked at Question No. 171: "It has no statutory recognition? (A.) That is so. (Q.) Can you tell us the name of its president or officers? (A.) Not at the present moment. (Q.) In every case, does the Home Office receive advice in regard to applicants for licences and certificates from that Association? (A.) Yes." So that it is a voluntary organisation of the promoters of vivisection, and it is consulted by the Home Office on the competence of vivisectors; and I do not know why, as we are also a voluntary organisation, we should not be consulted as to their humanity. But we are not. Desiring to find out, when I saw this evidence, what this Association really was, I could not find its address anywhere. I wrote in the air, and posted my letter "To the Secretary of the Association for the Advancement of Medicine by Research, London." The Post Office always find anybody, and they found him, I suppose. The letter I wrote was as follows: "Dear Sir,—In view of the enquiry now being made by the Royal Commission, I shall be much obliged if you will let me have a list of the members of your Association and the last yearly report, if you have one."

10676. (*Colonel Lockwood.*) When did you write that?—On the 24th of December, 1906, as soon as I saw this evidence. This evidence was given in October, and in December I wrote and asked for their last yearly report. I got a reply from the Association for the Advancement of Medicine by Research from 135, Harley Street, W., on the 29th of December, 1906, and it is in this form: "In reply to the Hon. Stephen Coleridge's letter of December 24th, the honorary secretary of the Association for the Advancement of Medicine by Research writes to say that he is unable to comply with the request contained in the letter." You see this gentleman did not even sign his name. I could not even tell who he was, but I looked up 135, Harley Street in the Directory, and it was the house, I found, of Mr. Charles Edward Beevor, who, I presume, therefore—I deduced—is the honorary secretary of the Association for the Advancement of Medicine by Research. But he gave me no information—he would not give me the yearly report or tell me who anybody was.

10677. (*Chairman.*) He is a doctor, I suppose?—I do not know. I suppose he is. I therefore prosecuted my further researches to find out what this Association was. I looked up old files of the "British Medical Journal," and I found in the number for the 1st of April, 1882, on page 476, that Sir William Jenner, at a meeting, concluded by proposing the following resolution: "That, with the view of bringing the legitimate influence of the medical profession more effectively to bear on the promotion of those exact researches in physiology, pathology, and therapeutics, which are essential to sound progress in the healing art, an association be formed, to be called 'The Association for the Advancement of Medicine by Research.'" Mr. Spottiswoode, then president of the Royal Society, moved also, at that same meeting apparently, "That the Association consist of representative members of the medical profession, and of other persons desirous of promoting the above objects." That is how it was formed. Then I find that on the 8th of April, 1882, a few days later, Mr. Hallowes, writing in the "British Medical Journal," on page 157, alludes to "The formation of a society to resist the opponents of scientific research," which, he says, "will be most welcome to the members of the British Medical Association." Therefore, he calls it a Society to Resist the Opponents of Scientific Research—that means us, I suppose, which is a misnomer, because we do not object to scientific research at all. Then in the "British Medical Journal" of the 22nd of April, on page 599, which is a fortnight later (I am doing this seriatim), I find a letter from the treasurer, who happened to be a Mr. Samuel Wilkes.

10678. What is this on?—I am showing you what the Association is, to which every application for a licence is referred.

10679. Could you not come to something which does show us what the Association is? All this history has very little to do with what the Society is now. This is the same Society that advises the Home Office?—Yes, this is the Society.

10680. But all this history of how you came to know what it is is immaterial?—I am only telling you what it is.

10681. I think you are telling us a great deal more than that?—This is a letter from a member of the provisional committee of it when it was first started, which contains these words, "The working physiologists"—that, of course, means the vivisectors—"of the three kingdoms have expressly stated that they do not desire (at least for the present) to attempt to abolish the Act, of which we are all ashamed, but to secure its being harmlessly administered. To speak with authority to public opinion, and to bring effectual pressure upon officials, needs other means than those which are suited to the arena of controversy."

10682. This is from a gentleman who is a member of the Association?—He is a member of the committee.

10683. In a letter written to the papers?—Yes; and he says that the object of this Association is to bring effectual pressure to bear upon officials—meaning the Home Office. Then the first report of the Council, dated the 29th of April, 1882, says that the first duty of the Association is "to promote those exact researches in physiology, pathology, and therapeutics which are essential to sound progress in the art of healing, and to remove any hindrances which obstruct these researches." Sub-committees were appointed to report (1) on the present hindrances to research due to the working of the Vivisection Act; (2) to report on the best ways in which exact researches in medical science (i.e., vivisection) can be encouraged"; and on the 13th of May we find a £500 prize offered for an essay on "The usefulness of vivisection as a method of scientific research, the conditions to be approved by the Association."

10684. Is not this rather beating the air? We all know that this Association is one that was formed for the advancement of research by vivisection, amongst other methods, and is very strongly in favour of it?—Yes.

10685. There is no doubt about that?—But I do not think that the Commissioners knew before that one of its objects was "to bring effectual pressure to bear upon officials."

10686. No, I am not aware of that. Is that a resolution?—That is what one of the provisional committee writes to the public press to say is one of their objects—"to bring effectual pressure to bear upon officials."

10687. In a large society, what one person who is a member of it writes to the press is not its best interpreter?—No, but further on you will see in the evidence that has been given before you that any licensed vivisector, on payment of 10s., may become a member of it, so that I think I am right in saying that this Association is an Association formed for bringing pressure to bear upon the officials of the Home Office, in order, if possible, to have the Act "harmlessly administered."

10688. Is there a resolution of the Society, or is there any printed rule of the Society saying that that is one of their objects?—My Lord, I have written to them in vain to get it, and I am thrown back upon this.

10689. I do not say that it is your fault that you cannot produce that rule if it exists, but certainly if that is the suggestion we shall have somebody from the Society (we have had one witness), and we will ask the question from him to ascertain it. But I think it is really taking up time unnecesarily to try and convince us that these gentlemen are all strongly in favour of vivisection—quite as strongly as you are against it?—Very well, if that be accepted, and that their object is to bring pressure to bear upon the Home Office——

10690. I do not accept that. I understand that somebody has written to the Press to say that that is his view.

(*Sir Mackenzie Chalmers.*) The pressure has not yet been felt.

(*Witness.*) Pardon me, I cannot accept that, if I may say so. I wish to point out in answer to that *obiter dictum*, that it is a fact proved before the Commission that the applications for licences are laid before this Association for the promotion of vivisection before they come to the Inspectors. Therefore the Inspectors receive these applications under prejudice, as they have already been before this Association of Vivisectors, before they reach the Inspector, who has to report upon them, and therefore it is put upon the Inspector.

10691. (*Chairman.*) I believe that is so; there is no dispute about that, is there?—Very well, my Lord, I think that answers Sir Mackenzie when he says that no pressure is brought to bear. I call that most distinctly pressure brought to bear upon the Inspector. Having finished my charges, I wish just to say in conclusion that I hope I have shown the Commission that the Home Office have repudiated the duty of protecting animals from unjustifiable suffering; that they have constituted themselves the consistent injudicial defenders of the vivisectors, protecting them from the punishment which it is their duty themselves to see inflicted upon them; that they have appointed biassed Inspectors; that they have given licences to men who have shamelessly and publicly proclaimed their personal inhumanity! that they have improperly allowed themselves, in our opinion, to be guided for years by a private society of vivisectors, formed for the very purpose of bringing pressure to bear upon them, if I may say so, to neglect that which they should do for the protection of animals; and I invite this Commission to acknowledge that I have laid before them ample evidence to show that the Home Office officials have for 30 years betrayed the solemn trust placed upon them by Parliament.

10692. The next point is the ethical ground upon which your Society objects to vivisection. I hope that you will place that before us very shortly; we have had it at extreme length already?—Perhaps the simplest way would be to submit myself to cross-examination on that statement.

10693. You say in a sentence that you think what is done is cruel?—Yes, I think that we have a right to kill animals, and that the duty is laid upon us in killing them to do so with as little accompanying pain as possible.

10694. Then you have in the course of your evidence already dealt with some of the statements made by previous witnesses. I do not know whether you have finished that part of your case?—I have some more statements of witnesses to deal with, but perhaps I had better keep that. I will do exactly what you like. I have the materials to go on with, but I will subject myself now to cross-examination on these charges or do anything you wish.

10695. You do at the end of your *précis* refer to certain alterations of the law?—Yes, I have my Bill.

10696. I think we had better deal with that, that is very much more practical, of course, than anything else?—I think perhaps it would simplify the discussion before the Commission if I were shortly to give you the alterations in the law which this Bill really would carry out.

10697. If you please?—I put them under 11 headings. The first alteration would be (1) the animal during the experiment to be under an anæsthetic of the nature of a respirable drug or gas.

10698. With regard to the present Act, is this draft which you have put before us by way of amendment to the Act, taking the Act as it is, and amending it?—Yes.

10699. It is not entirely a new Act repealing the present Act?—No, it is an amending Act. The second heading is (2) the animal to be killed before recovering from the anæsthetic. That is really re-instating the Act without Certificate B. The third, and this is really the important thing, is (3) the Inspector to be present throughout each experiment—each physiological experiment, of course, I mean; I do not mean experiments in the nature of inoculation. Provided that in the case of an "experiment not calculated to give pain from the act or operation by means of which the experiment is initiated." (By that I mean an inoculation experiment.) These three provisions shall not apply, but in lieu thereof (1) directly the animal feels pain it must be placed and kept under an anæsthetic, as above mentioned, or killed. (2) The Inspector shall frequently make surprise visits to all places where such experiments are taking place. The idea here is that the Inspector shall be present at all serious physiological operation experiments, but he is not necessarily present at inoculation experiments, which may, of course, last for weeks or months; but his duty will be to go at frequent intervals and inspect the condition of the animals which have been inoculated, and if they are in serious pain it will be his duty to order them to be killed.

10700. I thought you said that these three heads that you have given were none of them to apply to what you call inoculation experiments?—That is so, but in lieu of them there is this further direction that the

The Hon. S. Coleridge.

26 June 1907.

Inspector is often to make visits, and have them killed if they are in severe suffering. Then the next condition is (4) the total abolition of the use of curare, and after that the next one is (5) no application of matter to the eye of an animal for the purpose of observation through the conjectival membrane. (6) Abolition of certificates, and experiments depending thereon, of course.

10701. This is all confined, I presume, to experiments for the purpose of acquiring knowledge?—Yes. The rest of the Act stands.

10702. (*Sir Mackenzie Chalmers.*) You have dealt with lectures upon another point. You would prohibit all lecture experiments?—Yes, I am coming to that.

10703. (*Chairman.*) By providing that no application should be permitted to the eye, you did not mean that no oculist was to apply any application?—No, I mean for the purposes of experiment. Then 7. Licences to be granted only for one experiment or for one series of not more than six connected and consecutive experiments and must specify the time and place at which such experiments are to be performed and the nature of such experiments. (8) The licensee must make within seven days of completion of experiment a detailed chronological report in writing to the Secretary of State of the description, course, and result of the experiment, and is liable to penalties of £20 and £50 for first and subsequent failures to comply with these requirements.

10704. Within how many days?—Within seven days. Of course, I should have no objection to that period being lengthened, if it is found impracticable. I must put in some number of days. The next one is (9). That three copies of every licence granted by, and three copies of every report made to the Secretary of State shall be deposited respectively in the Library of the House of Lords, the Library of the House of Commons, and such other place accessible to the public as the Secretary of State may determine. (10) In the appointment of inspectors and licensees special regard is to be paid to the applicant's reputation for humanity, and (11) prosecutions may be instituted at any time within two years of the offence without the assent of the Secretary of State, the prosecutor, however, being bound to deposit the sum of fifty pounds as security for costs.

10705. (*Colonel Lockwood.*) To prevent any vexatious indictment?—Yes. Those are broadly the main provisions of the Bill.

10706. (*Chairman.*) Under No. 6, Abolition of certificates and experiments depending thereon, you mean the abolition of all certificates?—I meant Certificate B really. Certificate A remains.

10707. Do I correctly understand that that is what you put before as the minimum which your Society desires?—Yes, that is the Bill which I drafted which my Society supports, and which has been before Parliament with some small alterations for several Sessions.

10708. (*Colonel Lockwood.*) Are you able to differentiate at all between the ethical and practical views held by various people in this matter, or do you look upon the two as indivisible?—I look upon this question solely from the point of view of the animal. I do not deal with, and I do not address myself to the question of the utility of the practice of vivisection, if that is what you mean.

10709. What I mean is this. Do you hold the opinion that, if it was proved that certain operations lead to discoveries to alleviate human suffering, you would not object to them; or do you object to them altogether because you believe them to be immoral?—Not at all. My objection to vivisection begins and is centred in the question of pain. If an animal be placed under complete anæsthesia and destroyed before it recovers consciousness, personally I have no objection to that vivisection at all; and anything that might be discovered thereby would be to the benefit of humanity and welcomed by myself.

10710. We have had, as you know, various witnesses before us who refused to deal with what I call the practical side of the question, and dealt entirely with the ethical side. I will not go so far as to say that you dissociate yourself from them, but that is not the opinion that you hold?—I ought to say that I am not against the total abolition of vivisection, because in my opinion the total abolition of vivisection would be the most certain way of preventing any possible torture to animals and saving them from all possible pain; but as it is the pain that I object to, if the pain be really and truly eliminated from vivisection I personally have no objection to it.

10711. In the beginning of your remarks you said that you regretted that the Press were not admitted here because much that the public have a right to know (I think that is about it) would not be known by them?—Yes.

10712. Would you tell me and the Commission exactly what was in your mind when you said that in view of publishing the evidence?—First of all I should have liked to have heard the debate which was conducted among the Commissioners on the question of the introduction of the Press and the permission of myself and others to be represented by counsel. I think that would have been very illuminating to the public.

10713. You mean the preliminary talk of the Commission?—Certainly. On what ground it was that the Commissioners determined to refuse my application to appear by counsel.

10714. You alluded in the early part of your evidence to Queen Victoria's opinion being against vivisection?—I have Her Majesty's letter here. It was sent to the secretary of the London Society who kindly let me see it.

10715. (*Chairman.*) Is that from Her late Majesty?—It is from Sir Henry Ponsonby on her behalf. It is as follows:—"Windsor Castle, May 8th, 1889.—Sir,—I duly laid all the documents forwarded by you before the Queen, who was much interested in the report of 1888. The object of your Society is to effect the total abolition of vivisection, by which, of course, is meant the removal of laws which sanction it. It would be impossible for the Queen to take any part in petitioning Parliament or herself to pass new laws, and therefore, while heartily sympathising with your efforts, Her Majesty is compelled to decline the office of patron.—I am, Sir, your obedient servant, HENRY PONSONBY. The Secretary, the London Anti-Vivisection Society, 32, Sackville Street, Piccadilly, W."

10716. (*Colonel Lockwood.*) In the beginning of your evidence you alluded to the gross inhumanity of the medical profession, I think?—No, I never said that.

10717. I wanted to make quite sure. I made a note at the time, being very much struck by it?—I know what you are thinking of. I was very careful of what I said.

10718. Here I have it at Question 10262. "We are prepared to show that under the existing law there is no limit to the agony that may legally be inflicted upon animals, and we abominate a Statute that authorises gross inhumanity"?—Yes.

10719. Could you elucidate that a little for my information?—Yes; that is a plain statement of fact. under the present Act there is no limit. If a man has Certificate A, there is no limit to the agony he can inflict. I do not say that it does happen. I say that under the present law it can happen. I am not saying for a moment that at the present time provisions are not added to that Certificate which may prevent it under the law. But the Home Secretary might be a vivisector.

10720. When we were talking about Dr. Bayliss's operations not having been performed under an anæsthetic, would not the animal have cried out if it had not been under an anæsthetic?—I never said that. What I said was that "The anæsthetics during these prolonged and fearful mutilations can legally be applied by an automatic pump in another room."

10721. Would it not have been the case that if the pump had not acted properly and the dog was not insensible, there would have been some evidence of pain on its part?—Yes, I have no doubt, but then there was evidence that it did struggle, and the vivisector said it was St. Vitus's dance. They admitted the struggle, but said it was St. Vitus's dance. I do not know what they call it, but it was St. Vitus's dance.

10722. (*Mr. Wilson.*) Chorea?—Yes, chorea.

10723. (*Colonel Lockwood.*) At Question 10,264 you go into the question of fact, that the inspectors appointed by the Home Secretary have no testimonial as to their humanity?—I do not think I said the inspectors, did I?

10724. "Nor the inspectors appointed by the Home Secretary, testify to the personal character or humanity of the applicant"?—Yes, of the other people. I said nothing about themselves.

10725. Yes, it is the applicants. How are you going to meet that in your Bill?—I say that in the appointment of inspectors special regard is to be paid to the applicants' reputation for humanity. I say that certainly men like Dr. Klein would not get a licence under my Bill. His reputation is the other way.

10726. I mean how could you possibly arrive at getting a humane character for anybody excepting from an interested party?—I think it might be done.

10727. It seems to me very difficult?—I think inquiries might be instituted about a man's personal character, his character for humanity.

10728. You think by your Bill you could work it?—I do specify it. I say "a certificate recommending that the application be granted on account of the applicant's reputation for humanity, which must be signed by two or more of the following persons. That is to say, a Justice of the Peace, a minister of any religious denomination in the United Kingdom." That is as near as you can get.

10729. That you think would be sufficient safeguard?—Yes.

10730. And guide to humanity?—As much as one can expect.

10731. And you think that would ease the public mind as to the humanity of the person who got a licence?—Yes, always provided that the Inspector was present at every vivisection. That is what I look upon as really comforting the public mind.

10732-3. The presence of the Inspector invariably?—The presence of the Inspector invariably at serious cutting operations.

10734. In answer to Question 10265 you say, "It will be observed that my Society has been forced to the conclusion that, by placing the interests of the animals in the hands of the Home Secretary the framers of the Act of 1876, unwittingly, no doubt, made a fatal mistake. The Home Secretary has practically delegated much of his responsibility to the Home Office officials, who have, in their turn, delegated their responsibility," and so on?—Yes.

10735. You will acknowledge, I suppose, that the Home Secretary himself, beyond being, of course, the authorised responsible minister for these things, must delegate his work to somebody?—Yes.

10736. To whom would you delegate it?—I say that under the safeguards of my Bill, if it is passed, first of all any person may prosecute without leave of the Home Secretary, provided he is a serious person, and puts up £50 to cover the costs. That, in my opinion, takes the protection of the animals very largely out of the sole care of the Home Office, and allows such a society as mine, or any serious society, to do what they can to safeguard animals in the event of any breach of the law. But at present, I say it deliberately, I have no reason to suppose that any illegal act in the way of torturing an animal or anything of that kind has ever taken place hitherto in the presence of a Government inspector. I therefore rely (I am not a fanatic), upon the presence of a Government Inspector to protect the animal from illegal treatment.

10737. Do not you think that if this power was placed in the hands of practically anybody to prosecute, it would lead to a certain amount of carelessness on the part of the real official of the Home Office, the Home Secretary, because he would say, "Well, after all, anybody in the street, or in a society can take up this matter; I need not be extra careful on the subject"?—I do not think that. I think we can go by the analogy for instance of the children's society, of which I sit on the Council. In practice it is the society that institutes prosecutions; but therefore because the society institutes prosecutions I do not think (I have never observed) that it makes the police any more remiss in their readiness to assist or carry out the law.

10738. In answer to a previous question you said that you were not against experiments, provided they were not cruel to the animals?—That is so, as long as there is no torture of animals I do not object to it.

10739. And you do not dispute the fact that there have been discoveries made by these experiments which have been of use to human beings?—That is a question for experts.

10740. You would not like to express an opinion?—No, neither one way nor the other. What is my opinion against the aggregate opinion of the scientific men of this Commission? I do not set it up for a moment. Perhaps I might add, to elucidate that position of mine, that with regard to the results of vivisection, I see no objection to human beings benefiting by the results, provided that those results are not continually produced by fresh infliction of pain, and serious pain.

10741. You have probably read over Professor Starling's evidence?—Yes, I have read it through.

10742. You will have noticed, of course, that, as he would be expected to do, he traverses the various statemade by Mrs. Cook and various other people who hold anti-vivisection views. Have you any remarks to make upon the statements which he makes as traversing those statements?—No.

10743. In one part I remember he said, "That is absolutely false." For instance, he said of one of the witness's statement at Question 3672, which refers to some of Mrs. Cook's statements about cruelty to animals, "these scalped animals with mutilated nerves were allowed to live and then they were again anæsthetised. This is entirely false." Of course, I had read this statement of Mrs. Cook's before, and I confess to having been considerably horrified; but then, when I come to a skilled witness who says "This is absolutely false," it leaves rather an unpleasant impression upon my mind that I have been misled. Have you formed any opinion about it?—I have formed the opinion that as neither Mrs. Cook nor Professor Starling were present when these experiments were performed, they are both equally at liberty to form their own conclusions from what they have read.

10744. But you see Mrs. Cook's account was published to the public, and this evidence, of course, is published to the public, but the public will not necessarily hear of it?—I should like to go back if I am to be asked this, to see what this was. I do not know what Mrs. Cook was talking about at the moment.

10745. If you would just look over it?—I do not know what it is. If this quotation, "for three or four weeks these scalped animals with mutilated nerves were allowed to live," is a fact, it sounds rather horrifying. That is a question of fact. I do not know what Mrs. Cook is quoting from. I would rather she dealt with it herself.

10745. If you would just look over it?—I do not wish to ask you questions about which you have no personal knowledge?—No, I have no knowledge of it.

10747. (*Colonel Lockwood.*) Professor Starling says at Question 3772, that his view of experiments on living animals is "That science is advanced by experiment; that physiology is a science of living things, and that physiology will therefore be advanced by experiments on living things." Would you give me your answer to that?—I presume that, other things not being considered, physiology would be advanced and might be advanced at any rate by experiments on living animals, but whether physiology thus discovered is of any service to mankind is another question.

10748. (*Chairman.*) That is a point upon which I understand you do not wish to express an opinion?—That is so.

10749. (*Sir William Collins.*) I do not know that I have many questions to ask you in reference to your statement in regard to the Home Office. Do I correctly understand that your Society approves of the draft Bill, which you have laid before the Commission?—Yes.

10750. Then their legislative project is rather in the direction of amending than repealing the existing Act?—Yes.

10751. And though you might perhaps as a counsel of perfection desire abolition, I think your Society and you would be content with this amending Bill?—We think that to bring in a Bill for the total abolition of all vivisection in the present condition of public opinion would be a waste of time, and that meanwhile we think much good might be done by such a Bill as this to protect animals more than they are protected at present. And we should like to see how this Bill works if it is passed, if it ever becomes law.

10752. From a hasty perusal of your Bill, I do not see any provision in it for certificates such as those obtained under the present Act?—We leave Certificate A alone, but not certificate B. Certificate B is practically abolished in the sense that you must not allow the animal to recover. You may vivisect it as long as it is kept under anæsthetics and destroyed before it recovers consciousness, under my Bill.

The Hon. S. Coleridge.

26 June 1907.

10753. Do you make any distinction as to what animals should be used under your Bill?—No.

10754. Provided that the conditions of your Bill are carried out, you do not object to the use of dogs, cats, and monkeys?—I do not want to make any distinction between vertebrate animals.

10755. Have you formed any opinion as to the number of inspectors who would be required if your Bill became law?—Yes, if the Bill became law my hope would be that, instead of persons now vivisecting all over the country, when they had a serious object which would be recognised by the Home Office as a serious object, it would be worth their while to come to some central place, there to perform the series of operations under the eye of the Inspector which they wished to do; and I should look to a large reduction in the number of registered places, thereby saving the time and the travelling of the Inspectors. I see no reason for a very large increase in the number of Inspectors, provided that their whole time is occupied in inspecting, and provided that the places where they inspect are not too far distant from one another.

10756. Is there anything in the Bill which limits the number of registered places?—No.

10757. I do not think you told me the number of Inspectors that you contemplate?—No. I leave that to the exigencies of the case. At present the two Inspectors do not give their entire time, and inasmuch as they are not required to be present at every vivisection, they spend a good deal of their time in travelling about and seeing nothing, whereas under my Bill their services would never be wasted; wherever they were there would be a vivisection going on for them to inspect, so that an enormous saving of time would be made under my Bill.

10758. You set a good deal of store on inspection?—Yes, I do absolutely. Inspection is the whole thing in my Bill. In my view the present Act contemplates the necessity of inspection, but does not provide that it shall be efficient.

10759. On the ethical ground I understand that you direct yourself against the infliction of suffering, but you do not object to the utilisation of animals for scientific purposes, provided that it is painlessly conducted?—Quite so.

10760. Is it in your opinion immoral to use knowledge which has been obtained as the result of painful experiments on animals?—No, no more than it would be illegal or immoral for me to enjoy the results of a fortune accumulated in the slave trade by my great-grandfather. I need hardly say that he did not accumulate any such fortune, but if he had I should feel myself perfectly justified in enjoying that fortune. Although I should condemn the slave trade, and should certainly condemn its continuance now, or its resuscitation in any shape or form, I do not think it would necessarily morally preclude me from enjoying the results of the fortune. Nor do I think if any valuable invention has been discovered by painful vivisection of animals we are thereby precluded from using it.

10761. I understand that you do not contest the position that useful knowledge has been acquired by painful experiments upon animals?—That I neither admit nor deny, not being an expert.

10762. I do not know whether you are contemplating giving further evidence or whether you have dealt with that heading in your evidence with regard to statements by previous witnesses, dealing with the value of vivisection, both in physiology and in therapeutics?—I rather reserved myself for cross-examination upon that. Of course, though I assert nothing as to the usefulness of vivisection, as an ordinary layman it is open to me (as a layman) to criticise, if I can, any statement that is brought forward asserting great benefits to mankind in the way of lowering the death-rate from any particular disease. If the vivisectors were to claim that they had lowered the death-rate from any particular disease, that is a statement that, as a layman, I am as qualified to criticise as the greatest expert; and therefore in any case of that kind I should certainly not preclude myself, but simply for what it is worth I should examine the death-rates at Somerset House and think myself not precluded, though I am not an expert, from bringing them before the public.

10763. There are many previous witnesses who have called our attention, for instance, to the value of antitoxin as a mode of treatment for diphtheria, indicating that it has been discovered as the result of experiments on living animals, and that the serum is now obtained by a process involving the use of living animals. Have you any remark to make upon that evidence?—I have looked into the death rates from diphtheria before and after the introduction of antitoxin.

(*After a short adjournment.*)

10764. (*Sir William Collins.*) I think I was asking you whether you desired to say anything with regard to the claims which have been made by previous witnesses, as to the beneficial effects upon the diphtheria mortality arising from discoveries due to vivisection?—I have made a table here from the death rates per 1,000,000 persons living, and I think the fairest and best way to do it is to group it in quinquennial periods so as to avoid the slight inequalities of various years. I begin with 1876, and I come down to 1905. In the first quinquennial period, from 1876 to 1880, the average mortality per 1,000,000 persons living from diphtheria was 121; in the next quinquennial period it was 156; in the next 170; and in the next 253. That quinquennial period reaches down to the year 1895, and the "Encyclopædia Britannica" tells us that the antitoxin treatment began in the latter part of 1894; so that it falls just at the end of that quinquennial period. In the two quinquennial periods subsequent to the introduction of antitoxin in the first the death rate is 272, and in the second it is 204. That comes down to 1905. So that both the averages, taking the last two quinquennial periods covering ten years since the introduction of the antitoxin, are considerably higher than in the period from 1876; higher than the three periods during which the antitoxin was not used. I do not set any great store by that, except that there is the fact, when they claim to have cured this disease by this particular remedy, that the death per 1,000,000 persons living, appears to have gone up.

10765. May I revert once again to your draft Bill, and may I ask you how you deal with cases under that Bill, should it become law, in which animals have been inoculated with various morbid products with a view to ascertain the pathological effect?—Under my Bill if an animal is inoculated with a substance that creates a painful disease in it, it will be the duty of the Inspector to go and see that animal frequently, and if it be in a severe condition of suffering it will be his duty to order it to be killed painlessly.

10766. Of course in some cases, I suppose the painful symptoms might be expected to supervene somewhat rapidly after an inoculation?—As to that I presume that as the Inspector will probably be a man of some experience in these matters, and as he will know what the inoculation is from information sent in by the vivisector, he will know whether the painful period is likely to supervene early or late; therefore it will be within his power to protect that animal from unnecessary suffering.

10767. Do you think, under the provisions of your Bill, and with the inspection it provides, vivisection could be carried on without inflicting suffering upon animals?—I should hope so, yes. That is my hope.

10768. (*Sir Mackenzie Chalmers.*) I think you told us that you have never seen an experiment yourself?—No.

10769. And you never wish to see one?—No.

10770. And you have not any intention of seeing one?—No.

10771. Have you ever seen any animal after an experiment in a physiological laboratory?—No, I am wholly unacquainted with the thing from personal knowledge.

10772. Your knowledge is derived from reading?—Absolutely, and from what I have been told.

10773. Have you had communications with licensees, and discussed the question with them?—I know licensees; I have met them and talked to them.

10774. Do you accept their statements?—That is rather a large question.

10775. I will not press it?—It depends upon the man.

10776. I take it that your position is, that it is not what has been called the exploitation of animals that you object to, but the infliction of pain?—Yes, broadly that is it.

10777. Does the question of the amount of pain enter into your consideration?—Yes.

10778. Let us take one or two instances. You know that at present we are losing a million lives a year in India from plague?—I did not know that.

10779. And at home and in India certain experiments have been carried on to test the mode of transmission of plague—experiments on rats and guinea-pigs?—Yes.

10780. Do you think that these are justifiable, or not?—It depends entirely upon the amount of pain involved.

10781. The amount of pain involved in these experiments is to inoculate an animal with plague, which sometimes is a painful and sometimes not a very painful disease. Do you think it is justifiable?—Under my Bill it would be the duty of the Inspector to have that animal destroyed as soon as it manifested signs of severe suffering.

10782. You would not prohibit the experiments?—No, they would be permissible under my Bill.

10783. Take the case of the cancer research which is now going on. You agree that if any further information as to the nature or causation of cancer can be obtained, it is most essential?—Yes, but they have been some years at their researches now, and they have placed an almost inconceivable number of animals under test and under experimentation, and so far they have had no result whatever for the benefit of mankind; if the death rate per million persons living is to be any test at all.

10784. Do you think those experiments and the continuation of those experiments unjustifiable?—I should think it is about time that some period should be put to the numbers and the quantity of suffering that is inflicted for that purpose.

10785. Do you think that the induction of cancer in mice, which are chiefly used, is a painful experiment?—That is a matter for experts. If it be painful, I say it should be dropped as soon as the animal shows signs of severe suffering; it should be destroyed. There are cancers I believe in the human family which are not painful and some that are. I presume it is probable that it is the same with animals. I do not know.

10786. Then take the case of vaccination. The calf from which the vaccine is prepared suffers no doubt a considerable amount of inconvenience if not severe pain. Do you think that is justifiable or not?—I am an anti-vaccinator on the ground of the liberty of the subject quite apart from any other question.

10787. I am not dealing with compulsory vaccination?—I thought you meant that.

10788. I am dealing with vaccination which people are at liberty to adopt or not. We must have vaccine if people are to be voluntarily vaccinated?—Yes.

10789. Would that come outside your Bill or not?—That would not come under the purview of my Bill. That is a trade product you may call it. It is not experimentation for the purpose of scientific research; and my Bill only covers experimentation for the purposes of research.

10790. Any improvement in vaccine I suppose would be a matter of experiment?—Yes. Vaccine has been going some time. I presume it is a well-known product, is it not?

10791. Then to take the antitoxin for diphtheria, you were going to say something about that. Do you object to the preparation of antitoxin for diphtheria?—That I presume is also a trade product. It would not come under the purview of my Bill.

10792. I am not quite sure, but has not the antitoxin to be standardised by means of fresh experiments?—I do not know. I thought it was like vaccine, a thing that is now ascertained and is produced like a trade product. I thought you could buy it by the bottle.

10793. A good many experiments, as you know, are authorised for the purpose of standardising some of these preparations which cannot be standardised by chemical means?—If the Home Office issue licences for the purpose merely of what you may call standardising that is not an experiment, nor a new discovery; I consider that in issuing that licence under the present law there is no question of a new discovery there; therefore, I think such a licence is absolutely outside the Act, and ought not to be granted.

10794. If we are not justified in causing pain to animals for the purpose of alleviating human suffering and the advancement of knowledge, are we justified in killing and maiming animals in sport?—I am not a sportsman myself; personally, I have never shot a bird.

10795. I was not accusing you of being a sportsman; I was asking you whether, if the law deals with one, it ought not to deal with the other?—It does not seem to me to come within the purview of my Bill, but I am ready to give my own opinion, if it is of any interest.

10796. I want to know the view that your Society takes on this question?—My Society has no opinion on that matter; it is simply a Society for the prevention of vivisection, an anti-vivisection society. It has nothing to do with anything else. I should be absolutely going outside my rights and committing a breach of trust as regards its many subscribers if I devoted any of its funds for agitation against anything else.

10797. But may we have your private opinion; you are a very important member of your Society, and I should like to have your private opinion?—My private opinion is that you have no right to inflict unnecessary pain on animals in killing them, and therefore if any sport inflicted unnecessary pain on animals in killing them, I object to it myself personally. I should not do it myself. I do not bring any accusations against others who do, but I should object to it myself, and, so far do I object to it that I have done my best strenuously to support the Spurious Sports Bill now before the House of Commons.

10798. Take, for instance, rabbit shooting. No doubt a rabbit can be killed in a painless way, but in a good day's rabbit shooting a good many rabbits get away maimed, and die in their holes?—I never went out for a day's rabbit shooting, and I do not know.

10799. I was wondering whether it is a consistent attitude that you take up?—My consistency is perfect, because I do not shoot. I have never even hooked a fish. Nobody can say anything against my consistency. I can speak for myself; you asked me only to speak for myself.

10800. Is it a consistent attitude for your Society to take up, only to deal with one form of pain to animals, leaving probably infinitely worse forms of unnecessary pain untouched?—There is the Royal Society for the Prevention of Cruelty to Animals, whose purview is the whole cruelty performed in the world in all forms to animals of all sorts. My Society has taken up one particular form of cruelty to animals, and devoted themselves to it alone, because in their opinion the Royal Society for the Prevention of Cruelty to Animals has neglected it.

10801. You specialise?—Yes, and we think we can do it better than the Royal Society for the Prevention of Cruelty to Animals, even if they did do it, because we have devoted out entire attention to it.

10802. Colonel Lockwood called your attention to your evidence. Your Society publishes detailed accounts, does it not?—What of?

10803. Of its income and expenditure?—Oh, dear, yes.

10804. Do you know whether the other societies that you referred to published detailed accounts or not?—I think I have most of them here. I asked them all to send me their annual reports. I think they are here, if you like to see them.

10805. (*Dr. Wilson.*) You gave the annual incomes?—Yes; there they are, such as I have got (*handing in the same*).

10806. (*Sir Mackenzie Chalmers.*) I was not quite sure of the object of your statement in comparing the income of your Society with that of others?—My object was purely egotistical, to persuade the Commission, if I could, that mine was the most important Society in the anti-vivisection world, and to claim greater attention for my evidence than for that of small obscure societies which have hardly any address and no income.

10807. The point which occurred to me is this: What we have to judge of is not the income of the Society, but the validity of your arguments?—Yes, quite so. I hope mine have been more valid than those proposed by other societies.

10808. The smallest society might send a very important witness?—Yes; but every other society except mine, so far as I know, confines its attention solely to advocating the total abolition of any vivisection whatever, and they all differ from my Society, and somewhat

The Hon. S. Coleridge.

26 June 1907

acrimoniously on occasion, because we do not confine ourselves to that utopian policy, but are anxious and ready to advocate anything we can for the amelioration of the condition of vivisected animals. And I think it is a very valid argument in favour of our policy that the vast majority of anti-vivisectionists of England support us, and not them. That is why I brought those figures before the Commission.

10809. It will be convenient perhaps on that point to take some of the points in your Bill. Taking Section, Sub-section (3)?—I must apologise for the language "prior to." I do not like it; but that is prepared by a draftsman.

10810. "The animal must, prior to the commencement, and thenceforth during the whole course of the experiment, be under the influence of a general anæsthetic of the nature of a respirable drug or gas, such as chloroform or ether, or alcohol, chloroform, and ether combined, or sufficient power to prevent the animal feeling pain." That would abolish the present certificate B, would it not?—Yes.

10811. Because an experiment under certificate B consists first of the operative procedure, and then allowing the animal to recover from the anæsthesia?—Yes.

10812. That you would prohibit altogether?—That is my desire.

10813. The effect of that would be to prohibit Professor Starling's work on the digestive juices?—If you say so, I accept your statement.

10814. What he told us was that in what he considered important work on the digestive juices, the animal was put under chloroform, was operated upon, and a drainage tube was put in, and after the animal recovered, at stated intervals the digestive juice was drawn off. Those experiments would be absolutely prohibited?—It takes a long time to do that, does it?

10815. Weeks perhaps?—Then certainly I would prohibit it.

10816. Although he said that the animal was suffering really no appreciable pain?—I do not feel myself bound to take his statement on that point.

10817. The practical result of your Sub-section (3) would be to reproduce the existing licence and abolish Certificate B?—Yes. Certificate A I retain to a certain extent. Certificate B would be abolished.

10818. In fact, you draw no distinction between an experiment and an initial operation?—No, I think not. Our view, of course, is that it is under Certificate B that the animal has the greatest risk of suffering under the present law.

10819. Then by Sub-section (5) you would prohibit all demonstration experiments?—Yes, I should, on another ground besides on the ground of the animal, though I do not particularly object to it on the ground of the animal—that is to say, the animal is under complete anæsthesia, and destroyed before recovering consciousness. I think, on the whole, those conditions are more likely to be carried out in the presence of a lot of people than in the solitude of a laboratory. But I do think, from the evidence before this Commission, and from the evidence brought before us, that it does not tend to edification. I do not think it is right that young people should witness these things if they can be prevented. I do not think it is good for or tends to the edification of youth to witness these operations upon animals.

10820. Do you draw any distinction between witnessing operations of that kind on an animal and an ordinary surgical operation?—Yes, I draw a very large and grave distinction. In my opinion, when students go into the theatre of a hospital, what they are witnessing there is a beneficent operation undertaken with gravity by the surgeon for the benefit of the patient who lies there, and a totally different atmosphere of feeling must be present generally from that which obtains in a laboratory, where the simple thing is to find out whether the spleen does this and the blood pressure does that, and has no relation to the benefit of the animal of any sort.

10821. In fact, you disagree with the surgeons who have been here and given evidence on this question?—I decline to put myself up against anybody else. That is my opinion, and the reason I hold it. It is a reason which I hold with a great number of the persons whom I represent.

10822. Experiments should not be performed, you say, for the purpose of obtaining manipulative skill. That is the existing law?—Yes, I think it is.

10823. "The substance known as curare shall not be used or administered for the purpose of or during the experiment"?—Yes.

10824. Curare, if used now can only be used, you know, when a general anæsthetic is given?—It cannot be used, of course, under the present Act as an anæsthetic.

10825. We have been told that for certain investigations curare is essential; but you say that those investigations must stop?—My objection, of course, to curare is one which you must appreciate; that the most careful inspector cannot tell, if the animal has curare in a certain quantity injected into it, from any manifestations on the part of the animal when the real anæsthesia passes off. That is the sole reason I object to it. It is for the protection of the animal. It is impossible to protect an animal from the extremest torture if curare is permitted to be used at all.

10826. That is to say, the animal would make no manifestation; but it is quite possible to keep up the anæsthetic certainly and surely while the animal is under curare?—No, not certainly and surely. No one can tell whether an animal is suffering if it is under curare, except by manifestations which it makes itself of sensation.

10827. Not by knowing the amount of anæsthetic that is given?—You cannot know the amount of anæsthetic that is given from a bottle in another room. There may be a mistake, and every animal differs from every other animal. One animal will take more anæsthetic than another, and I should have thought that you yourself would have recognised the extreme difficulty in protecting an animal from pain if it has had curare as well as another anæsthetic. I feel sure that you must.

10828. I cannot give evidence, but I put to you this question. If a person who is skilled in giving anæsthetics gives the anæsthetic properly, surely there is no danger then?—What does the most skilled anæsthetist in the world do when he is administering anæsthesia to a patient? He does not merely watch a bottle and see how much he administers; he watches the patient for signs of life, and sensation, and it is by the signs of life and sensation in the patient that he is guided. I am sure that any anæsthetist would tell you that.

10829. Is not that for another purpose? Is not he afraid of the patient dying?—Very likely, but he is also afraid of the patient suffering, I hope.

10830. Perhaps some medical witness will deal with that. Coming to your Bill again—this refers to Certificate A: "Directly the animal begins to feel pain it must be placed, and thenceforth while it suffers or is likely to suffer, must be kept under the influence of a general anæsthetic of the nature of a respirable drug or gas such as chloroform or ether, or, alcohol chloroform and ether combined, of sufficient power to prevent the animal feeling pain"?—Yes.

10831. "Or if the animal is not so placed and kept under the influence of such anæsthetic as aforesaid, it must be forthwith killed"?—Yes, it practically comes to its being killed.

10832. That would prevent experiments which have the effect of producing any painful disease where it may be necessary for the experiment to let the disease run a certain course?—Of course, if it is a painful disease, yes.

10833. For instance, plague?—Yes, if it is a painful disease. I believe there are some forms of cancer, as I say, which are not painful—that people have it and suddenly die, never knowing that they had it. I have a cousin who died of it and never knew it.

10834. It would be rather difficult with an animal, would it not, to tell whether cancer is painful or not. Animals show very little sign of pain in case of chronic diseases?—I did not know that; I should have thought that they did. That is for the inspector to decide. If he says that an animal is not suffering at all, I am ready to take his word for it.

10835. You would stop any experiment?—Take such a thing as tetanus—that is what my eye is upon. If you inject tetanus into an animal it gets dreadful sufferings. I think that such an animal should either be placed under anæsthetics when it begins to manifest severe signs of suffering, or be killed.

10836. It struck me that your clause goes a great deal further than the actual cases you had in view?—I hope it will stop all severe suffering. That is the object of my Bill, and that is the object of those whom I represent, to stop suffering if we can—a laudable object, I should have thought.

10837. This will stop not only acute suffering but any suffering?—You cannot have a measure of pain. There is no such thing as a pain gauge after all. I have made it as wide as I can because I want to protect animals as much as I can. You see why I have done it—to protect animals as much as possible.

10838. Not being concerned, of course, with scientific results?—In no way whatever. If science can be advanced contemparaneously with painless vivisection I am glad to hear it; but I do not see why science should be advanced through suffering any more than any art. You would not allow any art to be advanced by suffering, or any other pursuit of any kind. You would not allow astronomy to be advanced by suffering. Why should you allow physiology to be advanced by suffering?

10839. I only wanted to get your view. There is no question of proportion. If any suffering is caused you would stop even what skilled people say is a most useful investigation?—I am not an unreasonable man. When I say suffering I mean real severe suffering.

10840. Would discomfort incidental to certain diseases come within your definition?—If the discomfort amounts to what is really serious, so that the animal is utterly wretched, I say that the animal ought to be killed.

10841. I think your clause goes beyond that?—I consider that the poor dog at Khartoum in that picture reduced to a hideous condition of emaciation, is cruelty. I think that animal ought to have been destroyed.

10842. I have not seen it?—There was a photograph of it, and therefore it must be true—at least I suppose so.

10843. Your third clause says: "There shall not be applied to the eye of an animal by way of experiment any matter or substance for the purpose of absorption through the conjunctival membrane." That would prevent, of course, the injection of cocaine?—It is not meant for that, of course.

10844. I am only taking the words?—I have seen books and pictures of wretched creatures' eyes in a hideous condition, and no doubt you have vivisectors who do use the eye, I believe, as the place for cultivating these dreadful germs, which produce a terrific state of suffering.

10845. I do not know whether your object was to prevent cocaine being used as an anæsthetic?—No, that is not the object of the clause; it is to protect the eye from being used as the nursing ground for bacteria.

10846. (*Chairman.*) You do not say there "any matter or substance likely to cause pain"; you say "any matter or substance"?—I daresay that is an error on my part; that is my intention.

10847. (*Sir Mackenzie Chalmers.*) I see what you mean. Then in Clause 8 you mention the persons who are to sign these certificates?—That is the old Act.

10848. Have you put in any obligation there that the names of the persons should be disclosed?—No, but I will now you mention it. I think that is most important. I quite agree with that.

10849. Under the existing law there is no such obligation?—I am not quite certain about that. I think the name certainly must be on the certificate.

10850. Yes, on the certificate?—That is all the clause says here. There is no obligation for you to publish a yearly report at all in the Home Office, so far as I know.

10851. Would it not be rather inconvenient for these people, who may be continually shifting and taking each other's place, to require their names to be published?—No, I think that anybody who signs a certificate ought not to be ashamed of having his name published in your report. Nobody looks at it except humanitarians.

10852. What is the object of having the names published?—I think that a man would think twice, or even perhaps three times, before he signed such a serious matter as a certificate exempting a man from using anæsthetics, if he knew that his name would be known to everybody as having done it. That would not preclude him, if he thought that the applicant was a proper person for a certificate; but I think it would make him a great deal more careful if he knew that his name would be published. I do not think that anybody would have been found year after year to sign a certificate for Dr. Klein if he knew that his name would be published for the world to see.

10853. On that, Dr. Klein has done nearly the whole of his work for the Local Government Board, has he not?—I do not know. If you say so I accept the statement.

10854. And under the instructions of the medical officer for the time being of the Local Government Board?—I suppose he is not the only person who could do that work.

10855. You are asking me a question that I cannot answer?—I think that some one else would have been better than a man who had proclaimed himself in public as inhumane, as he has.

10856. Are you aware that at the time when he gave that evidence he was, at least he said he was, somewhat imperfectly acquainted with English?—Yes.

10857. And that he asked to correct his evidence?—I know that, and I know also that the Royal Commission declined absolutely to have anything to do with his corrections.

10858. They published both his evidence and the corrections?—Yes. If you like to have this out I will give it you. Anything more condemnatory of his whole conduct cannot be conceived, in my opinion, than the whole thing. I have it here. Here it is, Dr. Klein's letter to the Secretary: "Dear Sir,—I return you my evidence corrected. I may mention to you that when under *vivâ voce* examination, the fact of my being a foreigner made me often not able to appreciate all the purport of the questions which were asked of me, and that therefore my answers were not always such as I would have desired to give if I had quite understood the questions. In revising the evidence I have endeavoured to remove the effect of any such misapprehensions.—I am, etc., E. KLEIN." Mr. Baker, the Secretary, replied: "Sir,—I beg to acknowledge the receipt of your letter of the 16th instant, together with the proof of your evidence, and to reply that, as your corrections appear to me to have exceeded the latitude usually allowed to witnesses, I must lay it before the Commission, and take their directions as to the course I am to pursue. I am, etc., NATH. BAKER (Secretary). P.S.—I must ask you to return me the proof I originally sent you, which you damaged, for, as I told you when I sent you the duplicate, I am answerable for all the copies that are supplied to me." Then Mr. Baker writes again: "In my letter of the 12th inst., in which I forwarded you a second proof I told you that I must have the original proof back. On the 17th instant I again asked you to return it to me. I regret that I must now formally request you to return it to me at once." Dr. Klein now replies: "Dear Sir,—I am very sorry to have given you so much annoyance, as it appears from your letter. As I have stated on the occasion of my asking for a second proof of my evidence, the first proof has been accidentally damaged so much that it was quite useless. I therefore destroyed it, and am not in a position, consequently, to comply with your request. I beg again to apologise if I should have put you to any inconvenience.—Believe me, etc., E. KLEIN." To which he gets this answer: "Sir.—Your letter of the 16th November has been considered by the Commission, with the proposed alterations of your evidence. These appear to the Commission to be so much at variance with the letter and the spirit of the answers you gave at your examination, that the substitution cannot be permitted. The Commissioners direct me to say that they observe with regret that after my letter of 12th November you should have destroyed the proof I originally sent you, and requested you to return. If you desire it, the Commissioners will include in the appendix your letter and the proposed alteration, with the correspondence which has passed with reference thereto." And they did it. In these circumstances, as I have been asked to produce that correspondence, I once more ask to be allowed to read Professor Huxley's letter to Mr. Darwin.

(*Chairman.*) I do not think that reading what you have now read makes any difference on the question of Professor Huxley's letter.

(*Witness.*) I only ask to read it, and it is refused.

10859. (*Sir Mackenzie Chalmers.*) We have not had Dr. Klein's corrections. I do not know what he wished

to say?—He watered it all down of course, but I should have thought that as the Commission declined to receive them it would not be material. But you can have them.

10860. (*Chairman.*) I do not understand from these letters that the Commission declined to receive his corrections; they said that they would publish them as his statement of what he wished his evidence to be altered to?—Yes, but they declined to accept them.

10861. No, they declined to strike out the evidence?—They declined to accept his corrections.

10862. As corrections?—Yes.

10863. They published both the evidence and the corrections?—Yes.

10864. (*Sir Mackenzie Chalmers.*) They published both and left the public to judge?—Yes. The Secretary said of the corrections: "These appear to the Commission to be so much at variance with the letter and the spirit of the answers you gave at your examination, that the substitution cannot be permitted."

10865. (*Chairman.*) The substitution?—Yes.

10866. (*Sir Mackenzie Chalmers.*) At any rate Dr. Klein himself wished to withdraw a good deal of his evidence?—No doubt he did.

10867. And, rightly or wrongly, he put it on the ground that he was a foreigner, and not very conversant with English at the time?—That is all quite true.

10868. Do you know whether it is a fact that he had done any operations except inoculations?—When?

10869. At the time when he gave his evidence?—I do not know in the least. How could anybody know?

10870. Was he not examined on it?—That must be a fact that no one can know.

10871. At any rate, since the Act, do you know whether he has done anything under his licence for the Local Government Board except inoculations?—I have not the slightest idea what he has done. He has the run of the laboratory at the Brown Institute, and as the Inspector is not there, I do not suppose that anybody knows what he has done. He has a licence.

10872. (*Chairman.*) Do you say that he is in the habit of conducting experiments at the Brown Institution?—I say that he is licensed to perform experiments there. I think he is still licensed.

10873. (*Sir William Church.*) But Lord Selby meant, would you please say when he ceased his connection with the Brown Institution?—That I will look out; I do not know; I am only speaking from my own memory, but it is easily looked up.

10874. (*Chairman.*) I do not know anything about him myself. Sir William Church tells me that it is a good many years ago, possibly 20, he does not know how long exactly, since Dr. Klein ceased to have any connection with the Brown Institution?—I do not think that is so. Here you are—"1904. E. Klein, Brown Institution, Wandsworth Road, London."

10875. (*Sir William Church.*) That was when he was acting under the Local Government Board?—I can only say that he is licensed to perform experiments at the Brown Institution. There is nothing in this Report about the Local Government Board; I can only go by what is published by the Home Office.

10876. I beg your pardon if I misunderstood you, I understood you to say that he was connected with the Brown Institution itself?—No.

10877. He was performing certain experiments there, but they were being done for the Government?—I do not know what they were done for. My sole statement is that Dr. Klein is licensed to perform experiments at the Brown Institution; that is all I know, that is all I state, and all that I ever meant to state.

10878. (*Sir Mackenzie Chalmers.*) You do not think it is very material what experiments he is authorised to perform?—I think it is very material what experiments he is authorised to perform. I may say in passing that I do not find his name in any medical directory. I suppose he is a foreigner, because he does not seem to have taken any degree in England. I am told he is a Fellow of the Royal Society. I did not know whether I was right to call him Dr. or Mr., that is all.

10879. Turning to your evidence in answer to Question 10262, Colonel Lockwood referred you to the sentence in which you say that you are "prepared to show that under the existing law there is no limit to the agony that may legally be inflicted upon animals," and that you "abominate a statute that authorises gross inhumanity"?—Yes.

10880. You know that the Council of the Royal Society have given evidence here by their President, who, on their behalf, pressed upon this Commission that the existing law and practice should be maintained?—You mean Lord Rayleigh?

10881. Yes. Do you charge him with inhumanity?—That does not arise out of my statement.

10882. I am asking you now?—I thought you were appending it to my statement.

10883. No, I ask you the question. The Royal Society support a statute which you say has this effect. Do you charge them with inhumanity?—Let me see what Lord Rayleigh did say. Will you tell me what it is you refer to, and I will look it up? I have the very greatest respect for Lord Rayleigh.

10884. You will find it in the second volume of our evidence, on page 53: "So much has already been gained from the application of experiments on animals, both for the progress of physiology and for the alleviation of human suffering, and so much more may be confidently expected in the future, that the President and Council trust that nothing will be done that would hamper he legitimate employment of the method"?—What has that got to do with my statement that the present law admits of any amount of torture? I do not want to be hypercritical. You seem to raise it on that statement of mine. I say it is not *ad rem.* Of course, if Lord Rayleigh says that a great deal has been gained from the application of experiments on animals, that is his opinion, and you are right to give it the greatest weight here, of course. I am not here to deny that.

10885. You are here to suggest an alteration in the existing law, which the Royal Society deprecate?—In any alteration of the existing law I trust that nothing will be done to hamper the legitimate employment of the method. Nor does my Bill do so. The legitimate employment of the method is not hampered by my Bill, but I consider that torturing animals is an illegitimate method—and I should hope that everybody would agree with me.

10886. (*Chairman.*) Do you say that the Royal Society suggest any alteration in the existing law?—No.

10887. That is all Sir Mackenzie Chalmers asked?—I do not say that they do. They have not seen my Bill; they have not had my Bill before them; they do not know what the suggestions are; they do not say anything about the law as a matter of fact; they simply say that they trust that nothing will be done that would hamper the legitimate employment of the method. There is no word about the law there or any alteration of the law. I find nothing of the sort to support that suggestion. On the contrary, in the very next sentence they say, "While precautions should undoubtedly be taken against improper use of experiments on living animals, it is not the province of the Society to suggest what safeguards should be adopted." As to that I suggest the safeguards which should be adopted to carry out Lord Rayleigh's intentions.

10888. (*Sir Mackenzie Chalmers.*) Then they go on: "It is, however, the bounden duty of the President and Council to urge that those safeguards should be so framed as not unnecessarily to interfere with that advancement of knowledge to promote which the society exists"?—I entirely endorse that.

10889. "Such restrictions would not only cripple or arrest the growth in this country of an important branch of biological science, but in so doing would reduce the efficiency of both physician and surgeon to mitigate or cure disease"?—I endorse every word of that. I entirely agree with Lord Rayleigh, but I maintain—and I expect that he would agree with me—that if the sole hamperings that I suggest are to prevent animals being tortured, provided that science is left free, those hamperings should be applied at once. I do not imagine that he would be so inhumane as not to agree to that, and if you ask me whether Lord Rayleigh is humane or not, I see nothing in this statement to suggest that he is not as humane as myself.

10890. Coming to the Royal College of Physicians, you have read Sir Douglas Powell's evidence, I suppose?—I have read it through.

10891. Is there any point that you wish to criticise on that?—Really I do not know that I have anything.

10892. I thought you said that there were various points in the evidence which you wished to criticise?—Yes, I have a list of them. I have got them in one packet here. I am ready to deal with them at any moment, if I am invited to do so. (*After referring to notes.*) Yes, I think I have something with regard to Sir Douglas Powell. At question 5,606 he was asked: "You do not believe that any cruelty, as we should understand it, is practised?" To which he replied: "I should say emphatically that it is not." Then "Have you ever seen any experiment in which the animal was allowed to recover from the operation without being killed? (A.) Not in recent times, not since the Act, certainly." I say that any statement, therefore, on the part of Sir Douglas Powell as to whether cruelty takes place under this Act is wholly out of court. He cannot speak of what happens when he is not there any more than I can; and I can, with equal emphasis, assure the Commission that cruelty is practised on equally good grounds. We were neither of us there.

10893. Are you aware that he said that he always considered carefully before granting a certificate as President of the College?—Yes, I daresay. If you say so, I accept it. He only considers the physiological fitness and the scientific eminence of the applicant; he does not pretend, nor does anybody, so far as I have seen throughout the evidence, that he takes into consideration the humanity of the applicant.

10894. Would it not be rather an impossible task to get evidence of humanity or inhumanity?—I should think not; at any rate, the effort might be made.

10895. I have heard of certificates of honesty, but I have never heard of certificates of humanity; I do not know on what evidence any such certificate would be founded?—I have suggested in the Bill how it should be done.

10896. You have suggested two clergymen or two justices?—No, one justice of the peace and one minister of any religious denomination.

10897. How could they know whether a man is humane or not; how can anyone know?—I presume that a man has friends who know something about him.

10898. (*Chairman.*) Is it essential in your Bill that he should have a minister of religion to speak for him?—The certificate must be signed by "Two or more of the following persons." Two justices of the peace will do perfectly well without any minister of religion.

10899. (*Sir Mackenzie Chalmers.*) You draw in your evidence a distinction between the Home Secretary and the Home Office?—You have done so yourself in one of your letters to me, which I read this morning.

10900. The Home Secretary speaks for his Office, of course?—Yes. I draw the distinction which everybody I suppose, with common sense, would draw, that the Home Secretary himself as the head of the Office passes away with the Government, and the permanent officials who are there always must of necessity take into their care such an Act as this, and I have no doubt that they do so.

10901. You know that the permanent officials are nearly as fleeting as the Home Secretary?—Oh, no.

10902. You will find it is so?—I hope not.

10903. For instance, in this way. Vivisection is in one branch of the Office?—Yes.

10904. A man is continually transferred from one branch to another, as a man gets promotion from one branch to another. The only permanent person is the Under-Secretary, for the time that he is there?—Oh, yes.

10905. Anyhow, what I want to come to is this. Many of the cases that you have referred to must necessarily have come before the Home Secretary himself. He has to answer the questions in Parliament?—Yes, but I assume, and I have no doubt it is the fact, that those answers are almost invariably prepared for him by the permanent officials of the Office; he does not write them of his own initiative. If you are prepared to tell me that he does——

10906. I cannot give evidence, but I can put the question in this way. The draft is prepared for the Home Secretary, of course, of the answer to be given in Parliament; that draft he considers himself, alters himself, asks for further information himself, as he wishes and pleases?—No doubt.

10907. And he ultimately is the person responsible?—Yes; that is a technical matter, which I must leave to you and your chief. It is for you to say who is responsible. I bring my indictment against the Home Secretary—and his Office, if you prefer it; only I think myself, and I have always thought, that it is the Home Office officials who really are the persons who frame these answers. The Home Secretary cannot be a master of all the details of an office of that kind.

10908. Certainly not?—Naturally.

10909. But if you take the people who have been Home Secretaries since the Act of 1876, the whole series of them—Lord Cross, Sir William Harcourt, Sir Matthew White-Ridley, Mr. Akers Douglas, Mr. Asquith, Mr. Gladstone—do you really think that they have not exercised independent control?—I am afraid I must answer that question very likely in some cases in the affirmative. I think it was under Sir William Harcourt that the habit grew up of consulting this Association of Vivisectors before a certificate was granted.

10910. That was instituted by Sir William Harcourt himself?—Yes. I dare say in big questions of policy of that sort the Home Secretary is the person whose word is taken, but in all matters of detail and all questions of routine, it is not so.

10911. Do you think that with all the attention that has been drawn to these matters in Parliament, each Home Secretary has not considered and laid down his own line?—No, I think they are immensely influenced by the officers behind them. I think it would be extremely difficult for the Home Secretary to take an entirely new line inside the four corners of the Vivisection Act against the settled habit, if I may say it, of the permanent officials, because settled habit it has been, as I have shown, I think. I think it is almost incredible that the same settled habits should be manifested under so many different heads, unless it were that the permanent officials were almost supreme in that matter.

10912. Have not the permanent officials, as I asked you before, altered almost as fast as the Home Secretary?—I have had a great number of letters signed by the same person, I know, through many years.

10913. You object to Sir William Harcourt's proceedings in making a reference to the Society for the advancement of Medicine by Research?—Most decidedly.

10914. Each licence and certificate goes to them. Are you aware what happens when they come back? Are you aware that certificates are continually altered and modified, and sometimes refused?—My point is that, so far no evidence has been offered here before this Commission to show that the Home Secretary has ever gone contrary to this association till the Commission was sitting.

10915. And, of course, there is no evidence, equally, that he has followed those recommendations?—The next thing I want to ask you about is this. You referred to Dr. Schäfer's drowning experiments. You are aware that his object was to verify the researches of a particular method of restoring the drowned?—I am not aware of it. I accept your statement. The object does not concern me.

10915A. It was a research carried out by him, I think, for the Royal Chirurgical Society, who wished to know what method ought to be recommended, there being four or five different methods of resuscitating the drowned. That, you will allow, is an important matter, as to what is the best method of restoring drowned persons?—Oh, dear, yes.

10916. Are you aware that Professor Schäfer performed 36 experiments?—I am not in the least aware of that. I will accept your statement.

10917. Thirty-four of those were under anæsthetics?—You say so.

10918. Does that affect your opinion of his experiments. You say that his experiments were regarded with particular detestation?—I did not say that. I said your permission to him was regarded with particular detestation.

10919. Does it make any difference in your opinion that 34 of those were under anæsthetics?—It may be that Professor Schäfer was much more humane than

The Hon. S. Coleridge.

26 June 1907.

the Home Office. The Home Office may have given him permission to do things which he did not do. My complaint is that the Home Office permitted him to do them, and they gave him a certificate that he might do them. I do not know whether he did them or not. My complaint is that he was permitted to do them.

10920. Thirty-four of those experiments were licensed under anæsthetics. He then applied (will you take it from me) for eight experiments without anæsthetics?—You say so; I know nothing about it.

10921. But he only performed two—will you take that from me? He considered those experiments unnecessary to control the conditions under which the anæsthetic experiments were performed?—The *gravamen* of my charge is that the Home Office gave Professor Schäfer leave to drown and re-drown the same dog without anæsthetics. That is the *gravamen* of my charge. What he did is not known to me nor to anybody but himself.

10922. Will you take from me what he did and what he wanted to do: that the two animals that were not under anæsthetics were not revived, but were simply drowned straight away?—What is your question?

10923. Will you accept his version of what actually happened: that the two animals which were not put under anæsthetics were drowned, and not allowed to recover?—You challenge me to make a charge of cruelty against Professor Schäfer. That is not my intention. I do not know Professor Schäfer.

10924. I am asking you about the actual experiments which were performed under the permission of the Home Office?—If your statement is correct it only proves to me that Professor Schäfer was more humane than those who gave him permission. You gave him permission to do something far more cruel than he actually did, if your statement is correct.

10925. There was a question asked about it in the House?—Yes, there was; that is what I am basing my answer upon.

10926. Will you read the question and answer?—I am afraid I have not got it here at the movement. (*The question was postponed.*) You do not traverse that statement of mine, that permission was given by the Home Office to drown and re-drown dogs?

10927. To test the means of resuscitation?—There was nothing in the certificate to prevent his drowning and re-drowning the same dog. I had that question asked in the House (I am sorry I cannot find it you now) and the answer was that Professor Schäfer had informed the Home Secretary that he had not done so.

10928. I do not think the certificate would ordinarily be in those terms. However, we can get the original certificate?—Yes. I am perfectly convinced that the permission given him was to drown and resuscitate dogs without anæsthesia.

(*Chairman.*) It must depend upon the document.

10929. (*Sir Mackenzie Chalmers.*) Anyhow, whether that is so or not, for the purpose of saving innumerable human lives, would not that, in your opinion, be justifiable?—I have not heard that one single person has been resuscitated in the country by these experiments yet. I have read the account, and so far as I can see the sole thing was, that you must put the person on his face so that the gravitation might act on the tongue and it would come out of the mouth; whereas the other way it would fall back and choke him.

10930. (*Chairman.*) That is not a full explanation of what he stated?—I read the account.

10931. I remember that he said more than that. One particular thing that he impressed was that a single person could do it with very few movements, whereas if you carry it out with the present methods it requires two persons if you are really to do it effectively, and it is a much longer process to set about.

10932. (*Dr. Gaskell.*) And the amount of air exchange was greater, and that any unskilled person can do it. You can describe by a photograph the exact method, whereas you can only teach the Sylvester method by means of a skilled teacher?—I can produce the question and answer in the case of course. I have not seen the certificate. We can get it to-morrow.

10933. (*Sir Mackenzie Chalmers.*) You think, anyhow, that even with the prospect of saving innumerable human lives such an experiment, if performed, was not justifiable?—My position is a very clear one on that. I say that the loftiest motive professed by persons who inflict pain and suffering upon animals does not justify their inflicting pain on animals. If so, as I said before in my opening statement, you might steal to devote the money to good purposes. An act is either right or wrong, and it is quite apart from the motive of those who perform that act.

10934. Do you object to drowning dogs as a means to getting rid of superfluous dogs?—I prefer the lethal chamber at Battersea.

10935. But if a dog is drowned right out it suffers no more if it is drowned in the course of an experiment?—I have always been told that the proper way to kill a dog is to shoot it—that that is the most merciful way, and I presume it is the way in which most people do it.

10936. In Edinburgh, at all events, when Professor Schäfer performed his experiments, and until recently, the mode of getting rid of superfluous dogs was by drowning, was it not?—I do not know. You know it is the resuscitating the dog and then drowning it again which was what I said was the *gravamen*.

10937. That as a matter of fact we were told was not done except under anæsthesia?—That may be.

10938. Now then we come to some experiments which certainly read as very horrible experiments, by Dr. Crile. You know nothing about those experiments except from Dr. Crile's own published report?—That is so.

10939. Would you accept his own explanation?—Certainly not; of course not. I read his book, and see what he says, and I accept that; but subsequent explanations when he is called upon to explain himself by the Home Office, if he was, I certainly do not accept.

10940. He was called upon, and perhaps I may read his explanation as given by himself?—I do not accept it for a moment.

10941. Whether you accept it or not, perhaps you will kindly listen to what he says?—Certainly.

10942. Dr. Poore wrote to him, The first letter miscarried, because he was in some out-of-the-way part of America. Then Dr. Poore wrote again, and he replied.

(*Chairman.*) What is the date?

10943. (*Sir Mackenzie Chalmers.*) There is no date of the year here. "Dear Doctor,—Replying to your favour of June 19th" (we can get the date from the previous letter) "I beg to say that in the entire series of experiments no animal suffered pain. The reference to the corneal reflex was correctly made, but the animal was not conscious. In the remark to Protocol XVI., page 31, 'At one time the anæsthetic was overlooked' simply meant that the animal had recovered far enough from the state of surgical anæsthesia to exhibit a corneal reflex, and begin a slight voluntary movement. By surgical anæsthesia I mean the administration of the anæsthetic to the same degree of anæsthesia as in the human subject in the performance of surgical operations. I wish to emphasise that in no instance did any animal suffer pain. In nearly every experiment I had a special anæsthetizer. As I am engaged in an active surgical practice, and have been for years, I feel myself quite competent to state that the animals I have subjected to vivisection have not suffered any more than the patients upon whom I have performed operations. And the latter, I know, have not suffered at all. The experiments were all performed as nearly as possible under the same conditions as operations on patients. I shall at once send a book to the Secretary of State. The delay in my reply was due to my being abroad—just returning yesterday. Thanking you for writing me, and if there is anything more that I can do, please let me know. Very respectfully yours, GEORGE W. CRILE, to G. V. Poore, M.D., 32, Wimpole Street, London"?—It is rather strange that he quotes that one statement that "the anæsthetic was overlooked" in the letter, and then goes on to say "The animal was coming out of anæsthesia, and the corneal reflex appeared." He did not read his own experiment, because the next words in the experiment are "The dog became profoundly under its influence," which, of course, meant that the dog had got too much, not too little, "Causing a very great fall in blood pressure of 40 millimetres in 85 seconds." So that in the book the overlooking was that it got too much, and in the letter the overlooking is that it got too little. You can look at the book for yourself. The first thing he

says in his letter defending himself shows that he is not accurate. So that he answered you without looking at his own book.

10944. Possibly?—In such a hurry was he to defend himself, in my opinion. There was no allegation against him in that experiment about anæsthesia, because it was there stated that the animal became profoundly under its influence.

10945. His letter refers to the whole experiment?—No, he quotes that particular one in that letter. That is the very one he picks out.

10946. "I wish to emphasise that in no instance did any animal suffer any pain." That refers to the whole?—Yes, quite so.

10947. Are you aware that Sir Victor Horsley saw a good many of these experiments?—I do not know, I am sure.

10948. Are you aware that he was of opinion that no pain was caused to the animal? We shall have his evidence—he is coming here?—No doubt he will say that.

10949. Are you aware that Dr. Goodbody also saw these experiments?—No, my whole position is that the Inspector should be there. If the Inspector had been there I should have been prepared to take the Inspector's word that these animals suffered nothing. The Inspector was not there, and I decline to accept the bare statement of the performer, particularly when this man himself, in his letter of excuse, clearly shows that he is not accurate.

10950. You accept his statement in the first instance, and you will not accept it in the second?—I will not accept Dr. Crile's statement at all.

10951. Will you accept Sir Victor Horsley's statement as a spectator?—Certainly not. I do not accept a person's account of his conduct in an experiment when his conduct is impugned, for one moment. I say that there should have been an inspector there. Parliament in its wisdom did not trust these men. If it had it would not have told you to appoint an inspector there to watch them. As the Inspector was not there I say I do not trust them. Parliament did not trust them; why should I? Parliament was not satisfied with their uncorroborated word as to what happened in their laboratories. Why should I be?

10952. We may have inspection, but still we may ask a person of character, when he saw the experiment, what his opinion of it was. You will not accept that?—Certainly not, because I think that all these experimenters have the greatest contempt for the Act of Parliament. They would deny a breach of this Act just as I should deny a breach of the Motor-Car Act. I drive a motor-car, and when I go beyond the speed limit, and a policeman asks me, I say, "No, I am not going beyond the speed limit." Nothing would keep me from going beyond the speed limit except the presence of a policeman in the car; and nothing will keep an experimenter within the four corners of the Act except an inspector in the laboratory.

10953. Surely if you were asked about the speed limit, and gave your word that you had not exceeded it, you would not expect to be disbelieved?—No, I do not say so. I said last year that, of course, I did, and I exceed it every time.

10954. (*Chairman.*) You are apparently not very ethical about motor-cars. If you apply your principles as regards motoring to the physiologists, you have very little to say against them?—What I have to say is that they regard the Vivisection Act of 1876 with the same contempt that I regard the Motor-Car Act as regards the speed limit. Every motorist who has a motor-car, of course, breaks the Act.

10955. What you said was that if you were going more than 20 miles an hour, and were stopped for it, you said that you were going less than 20 miles an hour?—No; on the contrary, I was asked, and frankly answered that I was going beyond 20 miles an hour. I did not mean that. I always frankly admit it. When I am summoned, and get to the law court, I always admit it.

10956. Then you must not be quite so hard on a physiologist as to say that men are not to be believed on their oath?—I did not mean that; I meant that they regard the Act in the same sense as we motorists regard the Motor-Car Act. We do not treat it with very great respect as regards the speed limit.

10957. (*Sir William Church.*) Some of us?—Some of us.

10958. (*Mr. Ram.*) You think that these people will tell a lie about this because they have a contempt for the Act?—I did not say that.

10959. That is what I gathered. You despise the Motor-Car Act, which says that you may not go more than 20 miles an hour. Therefore on the face of your evidence you would not mind saying what was untrue with regard to it. You say that these men have a contempt for the Act, and therefore they say what is untrue?—No, I say that they will break the Act with the same facility as I break the Motor-Car Act, for the same sense of any lack of morality about it.

10960. If one of these physiologists says, "I performed an operation, and I say the animal did not suffer," is that any reason why they should not be believed?—I do not think it is unprejudiced evidence. What do you expect them to answer? What would you expect Dr. Crile to say—"I, of course, torture the animals"?

10961. (*Sir John MacFadyean.*) The same as you do when you are asked about the speed limit?—The difference there is very great. Nobody regards anybody a pin the worse for exceeding the speed limit. Nobody, so far as I know or ever heard of, would hold it up against anybody as a moral fault to exceed the speed limit, but merely a technical breach of the Act; but I think that the public would certainly regard it as a moral offence if Dr. Crile were to admit that he tortured these animals.

10962. (*Sir Mackenzie Chalmers.*) We shall have Sir Victor Horsley's evidence, for what it is worth, as you say?—Yes.

10963. Do you suggest that the Home Office could have made any further inquiries than they did from persons who were present and from Dr. Crile himself?—I do not say that. I say that the present Act of Parliament is most defective, because they cannot get at present any information except from the person whose conduct is impugned. Therefore I consider that all the evidence that they get must necessarily be prejudiced. That is why I want the Inspector to be there always.

10964. But you agree, do you not, that the Home Office have to carry out an Act of Parliament as they find it, whether they like it or whether they do not?—Yes, I suppose that is so.

10965. Some Acts they may like, and some Acts they may not like, but they equally have to administer them according to the words of the Act?—Yes.

10966. And you know that as a matter of legal construction, not even expressions used in Parliament can be referred to, to gather the intention of an Act. You cannot refer to the debate in Parliament as throwing any light on the meaning of words used in an Act?—Is that so?

10967. It has been laid down pretty often?—I suppose that is so.

10968. Still less can you refer to the Report of a Commission, which may or may not have had anything to do with the foundation of the Act?—No, certainly there is a difference between a speech made in the House for or against an Act and the report of a Royal Commission upon which an Act of Parliament is based; at least I should have thought so.

10969. You have a Royal Commission, and then the Minister who prepares the Bill takes or does not take its recommendations, and in construing the Act you only have to look at the words of the Act itself which is the final expression of the Legislature?—I think that extraneous considerations are allowed. For instance, I have here Maxwell's "Interpretation of Statute," the fourth edition, page 30, "The liberal construction of an Act of Parliament) has, in general, but *prima facie* preference. To arrive at the real meaning it is always necessary to get an exact conception of the aim, scope and object of the whole Act; to consider, according to Lord Coke (Haydon's Case, 3 rep. 7b; 10 rep. 73a):—(1.) What was the law before the Act was passed. (2.) What was the mischief or defect for which the law had not provided. (3.) What remedy Parliament has appointed. (4.) The reason of the remedy. According to another authority (*per* Lord Justice Turner, in Hawkins *v.* Gathercole, 6, De G. M. G 1) the true meaning is to be found, not merely from the words of the Act, but from the cause and necessity of its being made, which are to be ascertained not only from a comparison of its several parts, but also from extraneous circumstances." Therefore I think you may call

The Hon. S. Coleridge.

26 June 1907

the Report of a Royal Commission an extraneous circumstance which ought to be taken into consideration.

10970. (*Chairman.*) You may think that is good enough for us poor Commissioners, but in a Court of Law I think you would find some difficulty in making that assertion?—It is Lord Justice Turner.

10971. He never said that you can interpret a statute by the Report of a Commission?—No, he does not say so, and I do not say so. He says that extraneous circumstances may be taken into account.

10972. (*Sir Mackenzie Chalmers.*) Is not that when the language of the Act is ambiguous, and not when the meaning of the Act is clear?—"We have therefore to consider not merely the words of this Act of Parliment, but the intent of the Legislature, to be collected from the cause and necessity of the Act being made, from a comparison of its several parts and from foreign (meaning extraneous) circumstances so far as they can justly be considered to throw light upon the subject." Those are Lord Justice Turner's exact words. I think that the Royal Commission does throw light upon the subject, so far as I can see. It is not very important.

10973. Further on you draw a distinction between the Home Secretary and his Department, which you have already mentioned. Of course, you agree that the Department is under this difficulty: that it never can reply. No officer of the Department who is attacked can ever reply?—I do not attack any individual in the Office, of course, and I have never done so. I have never done such a thing at all.

10974. I am not referring to the present time; I am rather referring to your objection to Dr. Poore. When Dr. Poore ceased to be Inspector, he made a speech of which you disapprove?—Yes.

10975. At the time when he was Inspector you and your Society had attacked him, had you not, as Inspector. You had raised various points about his inspection and his administration of the Act?—Very likely, about his reports.

10976. Then when he became a free man he retaliated?—I do not think that is so.

10977. You do not accept that way of putting it?—I think that his making that speech, so soon after he was relieved from the trammels of office, showed that he must have had a bias while under the trammels of office; and besides, I fail to see why criticism by my Society upon the Inspector should produce any personal animosity of that kind, or why it should find expression in such violent language.

10978. As a matter of fact, what he was doing was hitting back when he was a free man, was it not?—I wonder if he was ever criticised by the vivisectors.

10979. Then after Dr. Crile's experiment I think you wrote some letters to various surgeons?—I did.

10980. How many did you write altogether, do you know? We have got answers, I think, from seven?—I wrote to a great number. The vast majority did not answer me at all. I know that many more did not answer me than did. I really forget how many.

10981. Seven are all the answers that you got, I understand?—One from Sir Victor Horsley's secretary to say that he was away, and one from Professor Schäfer, and the rest from surgeons.

10982. You wrote a good many?—Yes.

10983. And you got answers from seven?—I wrote to many more than seven, certainly.

10984. Then there was some subsequent correspondence from some of them, was there not—Mr. Timothy Holmes and Mr. Owen?—I dare say there was.

10985. That subsequent correspondence we have not had?—I will get it.

10986. For instance, in the "Times" of March 15th, 1902, from Dr. Owen?—Yes, there was one letter to the "Times," I remember now.

10987. Shall I read it?—If you read his letter, I hope you will read my reply, if you have it.

10988. Yes. I have your reply too. This is from the "Times," of March 15th, 1902: "Anti-Vivisection Methods.—To the Editor of the 'Times.'—Sir,—When Mr. Stephen Coleridge asked me some time ago if it was true that at St. Mary's Hospital operations were performed on patients under incomplete anæsthesia, I at once sent him a reply in the negative. For, knowing his methods, I was afraid lest he was dressing up some horrible bogey, wherewith to shock a generous but emotional public, at the time when we were raising money to finish our much-needed Clarence wing. And, standing as it did, my reply was perfectly correct. But when I find Mr. Coleridge using it in support of his attack upon men of science, who, in a humane and lawful manner, are doing a necessary piece of distasteful work, of which Mr. Coleridge and I, and his and mine, and the whole community, may reap incalculable benefit, I must beg you to allow me to qualify it. For closing a cleft in a child's palate, and in certain grave operations on the tongue and throat, to have the patient in complete anæsthesia would be to invite disaster. But why should it be necessary to spread out these hideous things before the public gaze?—I am yours truly, EDMUND OWEN." To which you reply on March 17th, 1902: "Sir,—With regard to Mr. Edmund Owen's letter in the 'Times' of to-day, I asked him a plain question, and he gave me a plain answer. Now he says he wants to qualify that answer, and in qualifying it he states that he made it originally in the form he did for fear I should stop subscriptions to some ward they were building at St. Mary's Hospital! Mr. Owen's qualification of his original statement is that incomplete anæsthesia is employed in certain operations on the tongue and throat. The experiment of Dr. Crile I cited, and which took place under incomplete anæsthesia in Mr. Victor Horsley's laboratory, consisted in repeatedly crushing a fox terrier's paw. Mr. Victor Horsley and his friends are not likely to succeed in this controversy if they continue to enter the arena without previously consulting each other as to what they shall say.—Your obedient servant (Signed), STEPHEN COLERIDGE." Then you also had a correspondence with Mr. Timothy Holmes?—If you have got it there, by all means, if you will, read my reply.

10989. This is from the "Times" of March 17th, 1902: "Anti-Vivisection Methods.—To the Editor of the 'Times.'—Sir,—I see in a letter from the Hon. S. Coleridge in your paper to-day that he quotes from one which I wrote to him some years since. Mr. Coleridge is a complete stranger to me; but he has sometimes written to me about hospital matters, and the sentence which he quotes was in reply to a letter in which he seemed to be labouring under the strange delusion that hospital surgeons (for what purpose I know not, but I supposed him to fancy that it was for purposes of experiment) were in the habit of performing operations while their patients were still conscious of pain. Now, I was a hospital surgeon for more than a quarter of a century, and have performed hundreds and witnessed thousands of operations. I never heard of a case in which the patient was operated upon while conscious of pain, nor can I conceive why the surgeon should so act, and so I told Mr. Coleridge. I have, as I say, no knowledge of this gentleman, and have no right to speculate on his motives for the attitude he assumes towards our hospitals, but it seems to me a mistaken and a mischievous one. The researches carried on in our hospitals (miscalled 'experiments' by persons of Mr. Coleridge's views) have resulted in an immense saving of human life and human suffering, and anything that withdraws from our hospitals the public confidence and support appears to me a crime against humanity.—I am, Sir, yours faithfully, TIMOTHY HOLMES." I am afraid I have not got your reply with me.

10990. (*Chairman.*) Perhaps if we adjourn now you will be able to bring it next time?—Yes.

10991. (*Sir Mackenzie Chalmers.*) And will you bring any of these letters that you have got which we have not had?—Yes.

TWENTY-FIFTH DAY.

Wednesday, 3rd July 1907.

PRESENT:

The Right Hon. The Viscount SELBY (*Chairman*).
Colonel The Right Hon. A. M. LOCKWOOD, C.V.O., M.P.
Sir W. S. CHURCH, Bart., K.C.B., M.D.
Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir J. MCFADYEAN, M.B.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. A. J. RAM, K.C.
Mr. W. H. GASKELL, M.D., F.R.S.
Mr. J. TOMKINSON, M.P.
Mr. G. WILSON, LL.D., M.D.

Captain C. BIGHAM, C.M.G. (*Secretary.*)

The Hon. STEPHEN COLERIDGE recalled; and further Examined.

The Hon. S. Coleridge. 3 July 1907.

10991A. (*Chairman.*) I think when he finished the other day you had been asked about some correspondence between Mr. Timothy Holmes and yourself?—Yes.

10992. And you said you would probably be able to bring some letters to-day?—Yes, I have them all here.

10993. (*Sir Mackenzie Chalmers.*) I think I had read the letter of Mr. Timothy Holmes dated the 17th of March, 1902?—Perhaps you would like me to give you the results of my investigation at my office as to this correspondence. I have a very large number of letters. I have the whole correspondence here now; every letter that has passed between me and all these people. I have looked through all my books and letter books, so far as I can, and I have here a list of the eminent surgeons to whom I wrote, so far as I can make out:—E. Owen, T. Holmes, E. Nettleship, T. Bryant, T. W. Nunn, T. Bond, Professor Schäfer, Wm. Allingham, Jonathan Huthinson, Lord Lister, Sir H. Thompson, Mansell Moullen, Sir Victor Horsley, T. H. Openshaw, J. A. Kingdon, Noble Smith, Herbert Snow, M. F. Rees, G. D. Pidcock, J. May, T. J. Walker, G. W. Gosling, T. Walker, T. R. Jessop, J. A. Dearden, and S. F. Barber. I wrote to those myself. Of those Nettleship, Nunn, Allingham, Moullen, Sir Victor Horsley, Kingdon, Noble Smith, Rees, Pidcock, Gosling and T. Walker made me no reply. T. Holmes' reply was marked "private." I also find that I asked Lady Grove to write for me to Sir Frederick Treves, because she happened to know him; and I asked Lord Harberton to write to Walter Tyrrell, because he knew him; and I have the replies forwarded to me from those two gentlemen. I have all the replies now.

10994. All I was concerned with was, that some of the people you wrote to afterwards protested, rightly or wrongly, against the use you had made of their letters?—I do not think that is quite the way to put it. I have the correspondence here.

10995. I read Mr. Timothy Holmes' letter of the 17th March, 1902. Is there any reply to that that you wish to put in. I propose afterwards to read a letter of the 27th of March?—That I think is marked "private."

10996. I am only referring to a letter in the "Times"?—That cannot be marked "private."

10997. That is all I am concerned with. Do you wish to put in any reply to that letter of the 17th March?—Yes, I do. I wish to read my reply:—"To the Editor of the 'Times.' Sir,—Mr. Timothy Holmes is entirely inaccurate in stating that my letter to him suggested that hospital surgeons operated on their patients under incomplete anæsthesia, and I ask him either to withdraw this inaccurate statement or to publish my letter, which will disprove it. Although a very august authority had informed me that hospital patients were operated upon under incomplete anæsthesia—*i.e.*, before the corneal reflexes were abolished—I did not believe it, and wrote to Mr. Timothy Holmes, hoping that he would authorise me to deny it, which he did." The rest of the letter is on quite another subject; I do not know whether you want it introduced. That is all I say about Mr. Timothy Holmes.

10998. (*Chairman.*) You are speaking about vivisection, but not about this case?—It is on quite another subject. I am ready to go into it. I am answering two letters, you see, in my letter, at the same time.

10999. (*Sir Mackenzie Chalmers.*) Then a third letter came from Mr. Timothy Holmes?—Yes, on the 21st of March he writes to the "Times": "Sir,—I enclose a copy of the letter of Mr. S. Coleridge which he asks me to publish, and will leave your readers to judge whether I was inaccurate in saying that it suggests that hospital surgeons operate on their patients under incomplete anæsthesia; and then he enclosed my letter to him, which is as follows: "Dear Sir,—I have been recently informed on very high authority that surgeons now frequently perform severe operations on man under 'incomplete anæsthesia,' that is, while the eyelid still blinks when the eyeball is touched. As you may possibly be aware, I vehemently believe that animals are tortured in laboratories attached to our great hospitals, but I hesitate to accept this information charging our medical men with conveying the inhumanity of the laboratory into the hospital wards and operating theatre. I should be much obliged to you if you would tell me whether your experience leads you to endorse or deny this statement. Very faithfully yours.—Stephen Coleridge." My comment on that letter is that my letter in no way suggests for a moment that I believe it; on the contrary, I say that I do not.

11000. Then Mr. Timothy Holmes writes the following letter in the "Times" of March, 27th, 1902: "Sir,—I judge by your leading article to-day that you think you have given sufficient space already to this topic; but I hope you will find room for these few lines in reply (final as I hope) to Mr. S.

The Hon. S. Coleridge.

3 July 1907.

Coleridge"?—I have not seen that; but I am quite ready to hear it.

11001. "Mr. Coleridge (see his letter, March 20th) charged me with being entirely inaccurate in stating that his letter—a copy of which you published on March 21st—suggested that hospital surgeons operated on their patients under incomplete anæsthesia." As a matter of fact, what I had said (see my letter of March 17th) was that he appeared to have laboured 'under the strange delusion that hospital surgeons were in the habit of performing operations while their patients were still conscious of pain.' And if this was not the meaning of his letter, what could it mean? It is quite true that he says he hesitates to accept the information given him on very high authority to this effect; but as he also says that he 'vehemently believes' that animals are tortured in laboratories attached to our great hospitals, and talks of 'our medical men conveying the inhumanity of the laboratory into the hospital wards and operating theatre,' it is clear that he did believe it. Else why write to me—a perfect stranger—and, as it now turns out, to many others equally strangers to him, to settle a question that any surgeon of his acquaintance could have answered at once? It is quite evident that he confounds 'incomplete anæsthesia' with sensibility to pain, and that he had discovered the mare's nest which I alluded to. However, quite enough has been said about Mr. Coleridge and his opinions. I fully agree with the writer of your leader, that it is easy to attach too much importance to them; and, as far as the progress of physiology and medical science is concerned, I daresay they are negligible quantities. But at the present time our hospitals are seriously hampered for funds, and the misrepresentations of the anti-vivisectionists tend to frustrate our efforts to secure what is wanted. Only the other day a gentleman thus replied to the appeal from St. George's Hospital, which you, Sir, have so kindly supported: 'It would be impossible for me to give to any hospital of which I know that part of its income is used, not for the relief of the poor, but for a purpose which I consider immoral and detestable—the vivisection of animals.' I answered this gentleman," and so on?—I think if that letter is read and considered by this Commission, I am entitled to defend my entire conduct as regards the diversion of hospital funds to schools licensed for vivisection.

11002. (*Chairman.*) I do not see any object in going into it while we are talking about Mr. Timothy Holmes, unless you consider that you are attacked in any way?—I am quite prepared to defend every action I have taken.

11003. (*Sir Mackenzie Chalmers.*) I only read it for the purpose of showing that Mr. Timothy Holmes protested against the use made of his letters?—My answer to that, of course, is that I did not answer that letter; it did not need an answer. It is self-evident that he is wrong. I had never in my letters suggested anything of the kind that he said I did. On the contrary, I said in my letter distinctly the opposite, and asked him to confirm my opposite view.

11004. At any rate, he differed in effect as to that?—There can be no difference as to what English means. My letter meant one thing; he said it meant another.

11005. (*Chairman.*) I cannot accept that general proposition, I am afraid, upon a subject in which lawyers find great difference?—I fall back on Bishop Butler, who said "Words mean what they do mean, and not other things."

11006. He did not solve the question what they do mean?—No.

11007. (*Sir Mackenzie Chalmers.*) Probably you make an exception to your rule in favour of Acts of Parliament?—Well, that is rather sweeping.

11008. Then you read part of the Home Office letter to us last time. As the foundation of your letter to these surgeons, you read part of the Home Office letter of the 2nd September, 1899. I would rather have the whole letter on the notes?—My letter to the Home Office, do you mean?

11009. No; a letter from the Home Office to you. I would rather have the whole letter on the notes?—Certainly.

11010. You read a portion of it?—Did I? What is the date of it?

11011. Whitehall, 2nd September, 1899. It is in reference to Dr. Crile; you read a portion of it. Mr. Cunynghame wrote to you—"Sir, With reference to the sixteen experiments which were performed in this country by Dr. Crile, and to which you call the attention of the Secretary of State in your letter of the 18th May last, I am instructed to say that before these experiments were sanctioned the Secretary of State was advised that they would be wholly free from pain, and that their object was to study the phenomena of shock after surgical operations in spite of anæsthesia. Their object, therefore, would have been frustrated if the animals had been allowed to suffer pain. On receiving your letter, the Secretary of State caused investigations to be made into these experiments, and the information he has received from competent persons, who either witnessed most of the experiments or have read the account of them, is to the effect that in no instance had the animals experimented upon been subject to pain. At the same time he caused inquiry to be made of Dr. Crile, from whom the strongest assurance has been received that 'in the entire series of experiments no animal suffered pain.' The use of the term 'incomplete anæsthesia' has probably given rise to the misunderstanding. With regard to this, the Secretary of State is advised that there are various degrees of anæsthesia. In 'complete anæsthesia' the narcosis is very profound, and the 'reflex movements,' that is, the involuntary movements in response to an external stimulus, are suppressed. One of the last of these reflex movements to disappear is the blinking of the eyelids when the surface of the eyeball is touched, thence called the 'corneal' or 'conjunctival reflex.' But short of this is the condition termed by Dr. Crile 'incomplete anæsthesia,' in which the creature is quite insensible to pain, although the corneal and other reflexes can still be obtained. It is quite usual for even severe operations to be performed on man in this state of 'incomplete anæsthesia.'" (I read every word of this so far.) "Indeed in many cases complete anæsthesia could not be induced without great danger to life during the operation. But absolute freedom from pain exists, and the patients are wholly unconscious in this 'incomplete anæsthesia.' Under these circumstances the Secretary of State can find no reason to think that any offence has been committed against Section 3, Subsection (3) of the Act, which requires that the animal during the whole of the experiment shall be under the influence of some anæsthetic of sufficient power to prevent its feeling pain. I am, at the same time, to return the copy of Dr. Crile's work, and to thank you for having temporarily placed it at the disposal of the Secretary of State.—I am, Sir, your obedient servant. (Signed) Henry Cunynghame." I read the whole of that letter last time.

11012. Did you? I thought you only read an extract from it?—No, I read the whole of it, so far as I am aware. I had better read on now the whole of the correspondence, I think. To that a reply was sent from my office on the 16th September, 1899. This is written by myself.

11013. I never found the last part of that letter. I thought you stopped at the word "obtained"?—I may have done so; I do not think so.

11014. (*Dr. Gaskell.*) It is at No. 10,301?—The whole point is that last sentence on which I base my letter to the surgeons.

11015. (*Chairman.*) It is no good reading more letters about a matter which has been already passed?—(*After referring.*) I think you are right. I seem to have left out the important item of it.

11016. (*Sir Mackenzie Chalmers.*) You extracted the part referring to these medical men?—Yes, no doubt.

11017. Looking at it now, do not you think you would have saved correspondence with these men if you had set out rather more fully the Home Office letter?—I gave them the actual words: "It is quite usual for even severe operations to be performed on man in this state of 'incomplete anæsthesia'; and I gave the definition that you give me, namely, that the corneal reflexes were abolished.

11018. (*Chairman.*) What is the passage that was omitted in the letter that was sent to these gentlemen?—I shortened it a little, that is all.

11019. (*Sir Mackenzie Chalmers.*) You shortened it by leaving out "Indeed in many cases complete anæsthesia could not be induced without great danger to life during the operation, but absolute freedom from pain exists, and the patients are wholly unconscious in this incomplete anæsthesia." Those are the words which we should like to have seen in your letter to the surgeons?—I quite admit that. That is what you were

told by your advisers. I was not in the least inclined to place that advice before these surgeons. I wanted their independent view; I did not want their replies to be biassed by this advice from the Home Office. I placed the case naturally before them without any bias.

11020. You took a passage away from its context, and rather, perhaps unintentionally, altered the meaning of it?—No, I do not think so. That is only your advisers. It is a complete statement: "It is quite usual for even severe operations to be performed on man in this state of incomplete anæsthesia." That is the question I want to know, whether it was true or false according to the advice of these great surgeons.

11021. That sentence is very materially affected by its context in the reply to you, is it not? It is the introduction to what follows afterwards?—I think the only context which has any weight with it is "What is incomplete anæsthesia," and I used your advisers' definition of it, namely, "before the corneal reflexes are abolished." That is the only qualification necessary for getting an independent answer.

11022. I am not quite sure that I agree. The correspondence speaks for itself, I think, now?—Yes, I quite agree. I should like to go on with it.

11023. (*Chairman.*) With what?—With this correspondence; I do not want it stopped in the middle.

11024. (*Sir Mackenzie Chalmers.*) You quoted the letter, and all I wanted was the whole of it.

11025. (*Chairman.*) We may be going to inflict upon ourselves a great deal of correspondence that is not very material. We have had the letter that you wrote to the surgeons, and we have had their answers. You are now being asked questions as to whether certain of these gentlemen either had not the proper material before them or gave answers which contained passages which modified your view of their answers. That correspondence bearing on those points?—This is the correspondence between myself and the Home Office that I am alluding to at the moment. It is a letter that I wrote in answer to that to the Home Office. I do not press it.

11026. I do not know what it is?—I do not know either; I have not read it.

11027. The correspondence between you and the Home Office may be material. At the same time, I hope you will not read anything that is merely controversial correspondence?—It is on this question of incomplete anæsthesia, which is the whole point of this dispute between myself and the Home Office.

11028. But in the letter which has just been read they state the view of their advisers. The Home Secretary himself does not profess to know anything if he is not advised. We have your view about it?—This next letter shows what the views of those advisers are out of your own report, in which they define incomplete anæsthesia and complete anæsthesia themselves; and I thought it was *ad rem*: "Sir, I showed your letter of the 2nd September to Mr. Coleridge yesterday at his country house, where he, unfortunately, is laid up, and he desires me to point out that the distinction you now draw between 'complete' and 'incomplete' anæsthesia cannot possibly be unknown to Dr. Poore, the Government Inspector. Yet that official makes the following statement in his last report: 'In experiments performed under the licence alone, or under certificate C, the animal suffers no pain, because complete anæsthesia is maintained from before the commencement of the experiment until the animal is killed.' Mr. Coleridge therefore instructs me respectfully to inquire what is now the rule of the Home Office. Is incomplete anæsthesia permissible under licence alone, as you state in your letter under reply, or is only complete anæsthesia permissible under licence alone, as Dr. Poore states in his report? The other matters contained in your letter will have Mr. Coleridge's attention when he is better."

11029. I do not understand that Dr. Poore in that letter was drawing any contrast between complete and incomplete anæsthesia?—Yes, he says so most distinctly. He uses the words "complete anæsthesia," and defines it.

11030. How does he define it?—He says "The animal suffers no pain, because complete anæsthesia is maintained from before the commencement."

11031. That means that complete anæsthesia does produce it, but he was not contrasting complete with incomplete there. That was not the point he was on?—No. *The Hon. S. Coleridge.* 3 July 1907.

11032. Supposing he had used the words "The animal was in a state of complete insensibility to pain; that probably would have been expressing what he meant there. If you asked him to define the difference between complete and incomplete anæsthesia, and asked him whether the animals were always under complete anæsthesia in the strict sense of the word, or sometimes under complete anæsthesia without suffering pain, he might have given a different answer?—I think I am entitled, when a Government Inspector who is their adviser uses the phrase "complete anæsthesia" as being his way of defining a condition without pain, to deduce that when he uses the term "incomplete anæsthesia," he is defining a condition not without pain.

11033. He does not use it as a definition, I think. He says that complete anæsthesia includes a state of being without pain?—I do not think he says that.

11034. That is what it comes to. I do not think he is using it as a definition. We seem to be on very minute points with these verbal criticisms?—Very well, my lord.

11035. (*Sir Mackenzie Chalmers.*) I think I asked you whether you were aware that Dr. Crile's experiments were most of them seen by Dr. Goodbody?—You told me so. I was not aware of it before.

11036. Did you see a letter from Dr. Goodbody in "The Times" of the 13th March, 1902, who was present at the experiments, and gave his account of them?—No, I did not—not that I remember. I have something to say about Dr. Crile before I pass away from him.

11037. By all means say it?—I understand that one member of the Commission has a letter from other people, and has received evidence from other people who were present, all affirming that no pain was inflicted on the animals on this occasion. All I wish to point out to the Commission is this: There is no doubt that Dr. Crile in his own book admits that when he applied flame to the dog's paw, as he said, "The animal struggled on the application of the flame." That is a very definite statement by him.

11038. Was that one of the English experiments?—No, I quite admit that it was not an English experiment, so far as I know. It is not one of the first sixteen.

11039. (*Chairman.*) Then it is not one of those experiments about which you complained to the Home Office?—No; but I am only pointing out this, and I think it is *ad rem* in this way, to show that Dr. Crile is a person who does not hesitate to inflict what in my opinion is torture upon animals. He applied flame to the dog's foot, and the dog struggled on the application of that flame. I call that torture. There you have it under the man's own hand, the moment he gets out of England, that he does a thing which is undoubtedly torture of a most gross kind on an animal. I say under those circumstances, the whole book being before the Home Office, when they received that letter of excuse they ought to have taken into consideration what he did out of England.

11040. Had they got the book before them?—Yes, I placed that very experiment before the Home Office myself, and drew attention to the expression "flame was applied to the dog's paw."

11041. (*Sir Mackenzie Chalmers.*) When you called the attention of the Home Office to it, it was some time afterwards, and Dr. Crile had long left England?—Yes.

11042. What do you suggest that the Home Office could have done?—But my letter to you was before you consulted Dr. Crile as to what he had done; therefore, when you received his excuses you knew that he was a man who did torture animals, and his excuses, according to your own showing last time, were wholly incorrect, because he made a statement in the letter which you produced that was wholly false, showing that his evidence is not to be relied upon—first, because he was a man who did torture animals; and, secondly, because he was a man who, in his letter of excuse, was not a man incapable of making false statements.

11043. I should agree with you if Dr. Crile's evidence had not been confirmed by independent witnesses whom we have every reason to respect—Sir Victor Horsley

The Hon. S. Coleridge.

3 July 1907.

and Dr. Goodbody?—I only wanted just to get that out.

11044. Then I called your attention to Dr. Noel Paton's experiments on fasting, and perhaps it would only be fair if I read his own explanation in a letter written to Sir James Russell in response to a question as to how and why he performed these fasting experiments: "Dear Sir James Russell,—I suppose the experiments referred to by Mr. Thane in his letter of the 14th inst. are those published in 'The Journal of Physiology,' vol. xix., p. 192, *et seq.* (1895-96)." That is what you quoted from?—Well, Sir Mackenzie, if these letters are to be put in against me, I ought to have had them before I came here. It is very difficult for me to conduct my case from my point of view if things are thrown at me without my knowledge. This is a private letter, apparently, from Dr. Noel Paton to the Home Office. How can I deal with it without having it before me?

11045. (*Chairman.*) It is quite unusual for witnesses to be furnished with all the letters to be put to them. You must do the best you can, and we shall do the best we can?—It is very difficult for me, is it not?

11046. (*Sir Mackenzie Chalmers.*) "The experiments there described are upon the influence of fasting on the fats of the liver. I have always been most reluctant to inflict suffering upon animals, and before performing these experiments I gave them most careful consideration. I had already in 1888 studied the progress of a fast of thirty days undertaken by a Frenchman, Jacques, the results of which are published in the proceedings of the Royal Society of Edinburgh in 1889. I found that Jaques throughout his fast suffered no pain or distress—except for a curious attack of gout in the middle of the period."

11047. (*Mr. Tomkinson.*) He had water to drink, I suppose.

11048. (*Sir Mackenzie Chalmers.*) Yes, certainly he had. "I had also read the accounts given by Professor Luciani of a similar feat undertaken by an Italian, Succi (Das Hungern), and the descriptions of the fasts of Dr. Tanner in America and of Cetti in Berlin. In none of these did the abstinence from food, though extending over prolonged periods, cause inconvenience or suffering. Further, it is well known that many warm-blooded animals undergo prolonged fasts voluntarily and without suffering. Among mammals the male fur seal, I am informed, remains on shore in the breeding season sometimes for one hundred days without eating. Among cold-blooded animals very prolonged fasts are undergone without suffering or impairment of function, *e.g.*, in the salmon, in fresh water. Food is simply required as a source of energy, and so long as the animal body is not depleted of its stored material there is no necessity of a supply of food from without. From these considerations it seemed evident that the experiments I proposed to perform were not in any sense painful, especially as the animals were kept warm and supplied with water throughout the period. I therefore did not think that they could be brought under the Act, and I did not apply for a certificate. Indeed I do not know what certificate would have covered them. For the purpose of my experiments more prolonged fasts were desirable, but my repugnance to inflicting even possible discomfort upon animals prevented my extending the period beyond the limit of four days. No one has a greater love of the lower animals than I have, and all through my physiological career I have never willingly inflicted pain. I am, yours very truly, (Sd.) D. Noel Paton." That is his explanation, whether you accept it or not?—I understand the case to be that Dr. Noel Paton said that he did not consider that these experiments were within the four corners of the Act at all, and the Home Office accepted that explanation. My answer is that if any one of the Commissioners starved his horse for four days he would be summoned, and properly so, by the Royal Society for the Prevention of Cruelty to Animals, and probably convicted and fined. The law of the land would call it cruel, and any magistrate in the country would call it cruel. Before you pass on there are two or three things which were left open when I went away last time, and I should like to deal with those if I might. You put to me, for instance, at Question 10,914 a question on the Association for the Advancement of Medicine by Research.

11049. Yes?—"Each licence and certificate goes to them. Are you aware what happens when they come back? Are you aware that certificates are continually altered and modified and sometimes refused?" and I say, "My point is that so far no evidence has been offered here before this Commission to show that the Home Secretary has ever gone contrary to this Association till the Commission was sitting." Then Sir William Collins, at Question 3,873, asked Mr. Starling: "Do you know whether the Home Secretary ever acts contrary to the advice of the Association?" and Mr. Starling says: "He has done so lately, I understand"; and it continues: "(Q.) In how many cases?—(A.) He has in two cases lately refused to allow certificates. (Q.) During the present year?—(A.) During the last three weeks." That is what I based my assertion upon. I based it upon that evidence (I could not find it at the moment); and it is upon that evidence that I said my point was that no evidence had been offered "before this Commission to show that the Home Secretary has ever gone contrary to this Association till this Commission was sitting." The three weeks was within the period of the sitting of the Commission. I also want to point out before I leave this that Professor Schäfer himself, I see, in his evidence at Question 10,172 admits that the confidential reference to this Association in his own words is "clearly outside the four corners of the Act," though he states very naturally that he does not object to it himself. The next point is that there was a question and answer about Professor Schäfer drowning and redrowning dogs, which I could not find at the moment. I have found it and have it here; it is in "Hansard" of the 29th June, 1903. You will find the allusion to this under Question 10,925, etc., down to No. 10,928. It is as follows: "Colonel Lockwood: To ask the Secretary of State for the Home Department whether the certificate given to Professor Schäfer, in accordance with the provisions of the Act 39 and 40 Vic., c. 77, permits him partially to drown and then resuscitate the same dog without any anæsthetics more than once; and if so, how many times; or permits him partially to drown and then resuscitate the same dog without any anæsthetics only once; and if so, how many dogs has he permission so partially to drown and resuscitate." That is the question. Then Mr. Secretary Akers-Douglas answered thus: "The certificates obtained by Professor Schäfer for the purpose of testing the best means of effecting resuscitation in cases of apparent drowning are limited to ten experiments. It is not stated whether the experiments shall be on ten separate dogs, or whether the same dog will be used for more than one experiment; but I have ascertained that Professor Schäfer does not propose to submerge any unanæsthetised animal more than once." That is the question and answer I had in my mind when I said that the Home Office had permitted the drowning and redrowning of the same dog, but that I had heard with pleasure that Professor Schäfer said he had not done what he had been permitted to do.

11050. There was another question and answer on the same subject. Mr. Perks asked a question on the general question of Professor Schäfer's drowning experiments. Have you got that?—I am very pleased to hear it. I do not remember it.

11051. "Mr. Perks: To ask the Secretary of State for the Home Department whether, as reported at a recent meeting of the Committee of the Royal Medical and Chirurgical Society, Professor Schäfer has obtained permission to conduct experiments on dogs without anæsthetics for the purpose of investigating the phenomena of death from drowning; is he aware that these experiments have hitherto been conducted under chloroform; and will he take steps to prevent the infliction of cruelty which the experiments authorised involved"?—Was this after the other one?

11052. No, this was before the 15th June, 1903?—About a fortnight before.

11053. And Mr. Akers-Douglas in reply said: "Professor Schäfer has obtained the certificates required by the Act to enable him to perform certain experiments on dogs for the purpose of investigating, not the phenomena of death from drowning, but the best means of effecting resuscitation in cases of apparent drowning. The experiments will be performed on behalf of the Royal Medical and Chirugical Society of London, who have appointed a committee to consider this question. I am aware that Professor Schäfer has performed experiments on the effect of immersion on anæsthetised dogs, but I am informed that the use of

anæsthetics frustrated the object of the experiments. In view of the great importance of the subject in connection with the saving of human life, and of the strong recommendation received in support of the experiments, I have not felt justified in disallowing the certificates"?—The next point I want to point out is this. I could not find the number, Volume XV., of the Journal of Physiology. At Question 10564, Lord Selby asked: "You spoke of keeping the animal under anæsthetics first while it continued lying on the table," and so forth. "And then, in another place, you added the words 'until the wound has been aseptically closed.'" I say "I have not got the volume here now, I am afraid." I have got it now. This is an experiment by G. N. Stewart: "Experiment 2. Bitch, 3,708 grams. 50 mg. curare subcutaneously. Artificial respiration. Exposed right internal jugular vein, right carotid artery and right vago-sympathetic nerve, below thyroid gland —carefully separated right vagus from sympathetic for some distance. Cannula in left external jugular vein." There is no specific mention of anything in the way of anæsthetics, but 50 milogrammes of curare subcutaneously injected. This experiment is described as beginning at 2.2 in the afternoon, and it goes on till 8.14, and the point I want to make is this. There are curious notes all along down the side; I should like the Commissioners to look at this. It has been going on since 2 o'clock, and at 6.31 there is a note at the side "Curare action passing off; twitching of muscles." It does not say anything more was done to the animal to stop those twitchings or to allay pain, which I presume was beginning to be severe, or was severe all the time for all we know; but at 6.53 "injected 25 mg. curare into blood"—no doubt to keep the animal still.

11045. (*Colonel Lockwood.*) Where was this experiment?—I do not know where it was. It was done by G. N. Stewart, a licensed vivisector. He wrote several accounts of these experiments, and the difficulty is that he puts at the heading of this paper, which contains a great number of them, "From Physiological Laboratories, Cambridge and Strasburg." As he does not say which were done at Cambridge, in England, and which were done at Strasburg, if we convict him of cruelty—I do not say we do, but supposing he is convicted of cruelty in any one of these experiments, it is very easy to say that the pea at that time was under the Strasburg thimble, and not under the Cambridge one.

11055. (*Dr. Gaskell.*) If you look at the end of that paper, I think you will see a statement by Dr. Stewart on that subject?—Yes. "The above paper is based upon experiments made by the author while holding the George Henry Lewes Studentship in the Physiological Institute at Strasburg. The results were embodied in a report to the Government Grant Committee of the Royal Society, dated March 22nd, 1892. The paper formed part of a thesis sent in for the Goodsir Memorial Prize in the University of Edinburgh, April 30th, 1892, of which an abstract was read before the Physiological Society, June 25th, 1892." He says it again. "The experiments in the above paper were made," and so on. "In all the experiments performed in the Physiological Laboratory at Cambridge, and in most of those done in the Physiological Institute at Strasburg, the animals were anæsthetised with chloral, morphia, urethan, chloroform, or ether. When curare was given, it was generally in addition to one of these anæsthetics"—generally, not always.

11056. And in all the experiments in Cambridge the animal was anæsthetised?—No. "In all the experiments performed in the Physiological Laboratory at Cambridge, and in most of those done in the Physiological Institute at Strasburg, the animals were anæsthetised." What with? "Chloral, morphia, urethan, chloroform, or ether. When curare was given" (this holds with all of them, I presume) "it was generally in addition to one of these anæsthetics."

11057. (*Chairman.*) But if that statement is taken as a whole, it means that it was never administered without anæsthetics at Cambridge?—I quite admit that it is impossible to prove that any one of these experiments was not done at the Physiological Laboratory at Strasburg, but my point is that anybody who reads the account of this experiment through would think—I do not set up to be a physiologist, but it seems to me, and I have been advised (just as much as the Home Office has been advised)—that this is a most dreadful experiment. There are two points that I want to make on this experiment. My chief point is that, even if this were done (as it was admittedly done somewhere) at Cambridge, this could be done under Certificate B with perfect legality. That is one point which I wish to raise, because Certificate B permits animals to recover from anæsthesia so soon as the initial operation of the experiment has been performed. The initial operation here is carefully described, and after that there is no further operation upon the animal, so far as I can see by the notes at the side, from 2.2 to 8.14. We do not know whether the animal died, or what happened.

11058. (*Colonel Lockwood.*) I want to know whether curare was administered, according to the paper, alone, or in conjunction with anæsthetics?—According to this specific statement, there is no mention of any other anæsthetic, but there is this general statement, which seems to cover them all, in a sense. I admit it is a covering statement.

11059. (*Chairman.*) The statement is that if it was done at Cambridge it was done with an anæsthetic? —No, I say it need not have been so.

11060. Unless you say he is not speaking the truth; because he says expressly that in every case anæsthetics were used at Cambridge?—Yes, no doubt it was for the preliminary operation—the initial operation.

11061. Therefore, if he says that in some of the whole mass of cases curare was administered, then that means that in all the Cambridge cases, wherever curare was administered, it was after the anæsthetic; because he says that in every case at Cambridge there was an anæsthetic?—If he says that an anæthetic was used in all the experiments at Cambridge, I am not prepared to deny it. But I say that if he had Certificate B, as I presume he had, he was only bound to use anæsthetics during the initial operation.

11062. That is not the point. I was speaking of Colonel Lockwood's point. He wanted to know whether curare was used without an anæsthetic. I say that if curare was used at Cambridge, the statement is that an anæsthetic was used with it?—No, not necessarily during the period of observation.

11063. I am speaking of one operation, which is all he is speaking of. I do not know whether he says anything about using one or other anæsthetic during the period of observation?—That is the point.

11064. (*Dr. Gaskell.*) Were not these experiments done under licence? There is no Certificate B, so far as I know?—I do not know.

11065. (*Chairman.*) You seem to me to be making too much of this, and trying to get more out of his statement than it will bear?—No, my Lord; I am upon this: that Certificate B, as now issued by the Home Office, permits of any amount of torture, and I cite this as an instance.

11066. I was on what Colonel Lockwood put to you, and you answered it by giving an answer which seemed to me to relate to another matter?—To resume, what I mean is this, that this experiment was done either at Strasburg or Cambridge; if done at Cambridge, if he had Certificate B, it is perfectly illegal.

11067. (*Sir Mackenzie Chalmers.*) But had he Certificate B?—I will look and see.

11068. (*Mr. Tomkinson.*) Is your contention that if the word had been "invariably" instead of "generally" that would have covered it?—No, because when he said that he used anæsthetics that is perfectly true as regards his statement, because he would use it for the initial operation if he had Certificate B.

11059. But he says that when curare was administered it was generally in addition to an anæsthetic. If the word "invariably" had been used, it would have satisfied you that curare was never used without an anæsthetic?—During the initial operation only.

11070. (*Chairman.*) You are losing sight of the other part of what he says—that anæsthetics were always used at Cambridge. If this was done at Strasburg, that is another matter; he may have used curare without anæsthetics. But if it was done at Cambridge, it was an operation under the Act, and there must have been anæsthetics?—I am not citing it for that point. I cite it as an illustration of my contention that under Certificate B any amount of torture can be inflicted on animals in England under the present law.

11071. That is not immaterial at all, but it is not the question in point?—That is what I brought it up for.

The Hon. S. Coleridge.

3 July 1907.

(*Dr. Gaskell.*) That is a question which we shall come to afterwards.

(*Witness.*) My next point is this. Since I was here I have placed my Bill once more before my committee, and I have incorporated the various little alterations that were suggested. For instance, I have incorporated in Clause 3, about inserting matters into the eye, these words: "There shall not be applied to the eye of an animal by way of experiment any matter or substance." Then I put the words "calculated to give pain," which brings it up to and makes it more what I meant it to mean. Then also, in deference to something that was said, that in Clause 6, that the names of the gentlemen who signed the certificates would not necessarily by law be published, I have inserted, after the words "Secretary of State," in the third line, "and three copies of each of the two certificates hereinafter mentioned made in support of the application for the said licence if so granted"; and also in line 31, after the word "reports," "and certificates" should be deposited. That incorporates what Sir Mackenzie pointed out to me was an omission in the Bill. I laid it before my committee with those alterations on Monday, and they passed it with their entire approval. Then there was an allusion to the picture of a dog at Khartoum. Sir Mackenzie said he had not seen it; that is at Question 10842, so I have brought it here (*producing the same*).

11072. (*Sir John McFadyean.*) It was not done in England?—No, at Khartoum, under English Government.

11073. (*Sir Mackenzie Chalmers.*) The dog suffering from sleeping sickness?—Yes.

11074. (*Mr. Tomkinson.*) But that is put in as typical of the effects of inoculation, and as a case which may occur equally well in England?—Yes.

11075. (*Sir John McFadyean.*) Might I ask whether that picture is exhibited in order to convince the Commissioners that the dog must have suffered pain? Do you wish us to accept that as evidence that the dog must have suffered pain?—I should not care to have any dog that belonged to me reduced to that condition.

11076. That is not the question?—I should say that it was a condition of suffering, certainly. To the ordinary lay eye it is; it may not be so. To the ordinary lay eye it looks like a dog in a condition of suffering. I think that a man in England who reduced his dog to that condition outside his laboratory would be prosecuted by the Royal Society for the Prevention of Cruelty to Animals successfully, if the dog was seen in court.

11077. But, I suppose, as a layman, you would admit that there are absolutely painless diseases which reduce dogs to such a state of emaciation as that?—That is a question for an expert. I do not know. I daresay there are, if you say so.

11078. I ask whether you suggest the contrary?—I should myself say, as a layman, that evidence might be brought before the court that it was a perfectly painless condition, by experts. That would be for the judge and jury to decide.

11079. (*Dr. Gaskell.*) Is not that the characteristic of sleeping sickness—emaciation without pain?—That I do not know.

11080. (*Sir John McFadyean.*) So that it does not, as it stands, prove that this animal suffered?—I do not say it does.

11081. It is a perfectly reasonable supposition that this dog suffered no pain, in spite of the emaciation?—It seems always the supposition that any animal vivisected for anything suffers no pain. It is a supposition, I suppose, that can be accepted for purposes of argument.

11082. (*Sir Mackenzie Chalmers.*) With reference to your statements about Sir Victor Horsley, are you aware that he applied to the Home Office to be allowed to perform certain experiments with regard to disease caused by *filaria sanguine hominis*?—How could I possibly be aware of that?

11083. Which only arise at nighttime; and he asked, therefore, to be allowed to experiment outside laboratory hours?—You put that in the form of a question to me, but you know perfectly well that I know nothing about it.

11084. You complain of the permission being given, and I was asking if you knew the reason why it was given. You do not know?—Of course, I do not.

11085. (*Sir William Collins.*) Have these applications and the permission given thereon been published in any official return?—No, none.

11086. (*Sir Mackenzie Chalmers.*) You know the fact, but you do not know the circumstances which lead to it?—I am perfectly indifferent, and so are those whom I represent, as to what reasons may be assigned on which Sir Victor Horsley asked to be permitted to be placed outside the provisions of the Act. My complaint is that Sir Victor Horsley was given permission to vivisect in a place outside the region of inspection, and therefore outside the Act altogether, which contemplates that every place should be inspected.

11087. Are you aware that Mr. Asquith attached a condition to that leave that Sir Victor Horsley should report to the Inspector on each occasion when he performed any experiment at any but a registered place?—No, I am not aware of it.

11088. If you are not aware of it, why complain?—I have stated my complaint, and will state it again. It is immaterial to us, or to anybody whom I represent, for what purpose Sir Victor Horsley was placed outside the purview of the Act. Our contention is that no vivisector should be placed outside the possibility of inspection, and that the Act of Parliament did not contemplate anything of the kind, and did not intend it to be so.

11089. (*Chairman.*) Do you say that it is contrary to the Act?—We say that there is no reason in the world why Sir Victor Horsley should be placed by the Home Office outside the possibility of inspection. In the case of persons allowed to place grouse on a moor for the convenience of experiments, that is a different thing.

11090. This was not a case of that kind?—No, I understand that it was not.

(*Sir Mackenzie Chalmers.*) This was an inoculation experiment.

11091. (*Sir William Collins.*) Are the endorsements or conditions of a licence published in the official returns?—Never; the Act is administered, if I may say so, in the strictest secretary.

11092. (*Sir Mackenzie Chalmers.*) Then you raise a point as to Professor Schäfer's certificates. I can only put it to you for the purpose of clearing it up. You applied to the Home Office to know by whom Professor Schäfer's licence was signed?—Yes.

11093. I do not know that it is very material. May I put it to you in this way: That his application for a licence was signed by Sir Joseph Hooker and Sir John Burdon Sanderson, as you said?—That is a new name; I never heard of Hooker.

11094. And Burdon Sanderson?—The Home Office said that Sir John Burdon Sanderson signed his certificate.

11095. That is so?—That is my statement.

11096. Then his lecture certificate, Certificate C, was signed by the same people. Then he afterwards held various certificates from various people for special researches?—My contention was that it was impossible for the public to ascertain by any means published by the Home Office who signed these certificates. When we tried to investigate it the Home Office seemed confused, and could not tell us. The Home Office said one thing, and Professor Schäfer said another. The two statements are contradictory.

11097. They are not contradictory. One referred to Certificate B and the other to Certificate C?—There is a fourth man in now, Hooker. I never heard of him before.

11098. You objected to Sir William Harcourt asking the advice of the Society for the Advancement of Medicine by Research?—I do not put it upon Sir William Harcourt. It was done in his time.

11099. At any rate you objected to it?—Yes.

11100. I want to ask you this: Do you think it would be better if, say, a committee of the Council of the Royal College of Physicians was substituted for that society?—That is a very large question. I am not the adviser of the Home Office.

11101. I am asking you?—I am making the com-

plaint. If you ask me to say at a moment's notice I decline to give an opinion.

11102. I ask you whether, in your opinion, it would give a greater sense of security to you and your society?—The sole reason why all those who sign certificates sign them, so far as I understand it, is as testimonial to the scientific fitness of the applicant. Their scientific fitness is of no interest whatever to myself or my Society. Our interest is in the animals and their fate; and it is a matter of perfect indifference to us whether these gentlemen have scientific fitness or not.

11103. But the Society for the Advancement of Medicine by Research do not sign certificates; they are merely consulted. I am asking you whether you would have more confidence, for instance, in a committee of the Royal College of Physicians or a committee of the Royal Society of Medicine, if they were consulted in lieu of the Society for the Advancement of Medicine by Research?—I should have much more confidence if any body was consulted upon which there were no licensed vivisectors sitting. This society that you do consult is a society composed very largely of licensed vivisectors.

11104. (*Chairman.*) Then you would not approve of the Royal College of Physicians?—Not if the persons sitting on that committee to give that advice were licensed vivisectors.

11105. (*Sir Mackenzie Chalmers.*) But if you had a committee of the Royal College of Physicians who were not licensed vivisectors?—I should certainly regard it with greater respect. I think they would very likely take into consideration the humanity of the applicant. But even then they are not asked that. I have never had any evidence before me that the Home Office ever ask the persons to whom they refer what the humanity of the applicant may be.

11106. It is not the Home Office that grants certificates. The certificates are granted first, and the only question is whether the Home Office shall disallow them?—Yes; you can veto them.

11107. However, that suggestion does not approve itself to you?—I do not say that.

11108. Is there any body with expert knowledge that you can suggest in preference to the Society for the Advancement of Medicine by Research?—I should say that any body is fitter than the Society for the Propagation of Vivisection, which is really a better term for them.

11109. (*Colonel Lockwood.*) You have got no definite body in your mind at the present minute?—No, I am not interested in the scientific side of the matter. These men only testify to the scientific fitness of the person. If you ask me who are the right persons to ask as to the humanity of the applicants, I think that a committee of the National Anti-Vivisection Society would be a very proper body. It is just as public a body as this private association is, and just as able to give proper consideration to the humanity of the applicants as that other body is to consider their scientific fitness.

11110. (*Sir Mackenzie Chalmers.*) You raised the point, and it is a material point, about prosecutions under the Act. At present, as you know, all summary prosecutions are limited by six months?—Yes, by the Summary Jurisdiction Act.

11111. You suggest a longer period?—I suggest it, because, as you are aware, at present the yearly report, which is one of our sources of information, seldom comes out till about three or four weeks before that six months has elapsed; so that there is no possibility that a prosecution can be based upon that report, even if it revealed any breaches of the law. And, again, this short six months precludes us from taking advantage, as a rule, of any publications of the vivisectors, if by a slip they let out that they have broken the law, because they do not, as a rule, publish them until six months after the experiments.

11112. But it would, of course, be applying a special law to vivisectors which is not applied to the rest of the community; it would be an exception to the general law?—I do not see why. There is a definite reason that I give you, which, I think, is a reasonable one, and I think anybody ought to see is a reasonable one. I do not imagine that even the Home Office want to place vivisectors beyond the possibility for indictment for an offence under this Act.

11113. Certainly not?—I am not sure that putting them under the Summary Jurisdiction Act is not an exception in their favour.

11114. They are not put under it. It applies universally, does it not?—I do not know.

11115. As regards the prosecution of licensees, you do not think it is the duty of the Home Secretary first to give leave to prosecute, and then himself prosecute?—I think the provisions of my Bill are more desirable.

11116. But under the existing law you would hardly contend that the Home Secretary should give himself leave to prosecute, and then himself prosecute?—I think he should prosecute in cases where the law is broken.

11117. When he has given the licence?—Yes.

11118. Inasmuch as under the Act the prosecution requires his leave, do you think that the Act contemplated that he should give himself leave and then prosecute?—I should have thought it was possible for the Home Office to move in prosecutions. I should have thought that they could direct a prosecution against the man. I should be surprised if they cannot.

11119. Under that Act, wherever the Home Secretary has to give leave, do you think the Act contemplates that he should himself prosecute?—Why not? I see no reason agains it.

11120. That he should simply say, "I hereby authorise you, Herbert Gladstone, to prosecute," and then proceed to prosecute?—That is mere formality.

11121. I will take your answer upon that?—It would not be a formality which would frighten me if I were Home Secretary.

11122. You are aware that the Home Office has no legal department whatever?—I daresay.

11123. In how many cases have your Society asked for leave to prosecute? Are you aware of any case?—Not since I have been there, of course, because there was no possibility to get material for prosecution under the present law.

11124. You have not applied?—Naturally; how could we get the material to prosecute?

11125. There is only one small point I want to ask you about as to Dr. Grünbaum's experiment. Do you know that he was experimenting at that time under his certificates with antivenin?—How could I know that? That is your evidence. It is not a question to me.

11126. I am asking you whether you do know it?—Of course I do not.

11127. Was not all that happened this: that after a lecture in his own laboratory he went on with an experiment he was conducting, in the presence of certain chemists?—That may be your version of it. I was not there. That is not the account which was published in the papers.

11128. And, apart from any technicality, what is your objection to these chemists seeing the experiment?—My personal objection, you mean?

11129. You make it a ground of complaint?—I am here in an official capacity.

11130. I say (identifying you with your Society), is it not better, if experiments are performed, that they should not be performed wholly in secret?—Unfortunately, when I complain of that (because at present we are under the Act 39 and 40 Victoria, cap. 17), and I say that an illegal act was done under that Act, the Home Office take no notice of it. The Home Office cannot defend themselves by asking me whether, in my opinion, the law is wrong or right.

11131. I say, apart from technicality (I am quite prepared to deal with the technicality), you allege a substantial breach of the law?—Certainly.

11132. You said that it was illegal that these experiments should be seen by skilled persons—chemists. They are not the general public?—They are not physiologists, I think.

11133. They are persons who would sell antivenin if antivenin came into use?—My point is that an illegal act was committed, and the Home Office condoned it. That is my point.

11134. That is a matter of dispute, of course?—Yes. I only say that that is my point, for what it is worth.

11135. Then you complained of some experiments performed in Ireland. You know that the Irish Office

The Hon. S. Coleridge.

3 July 1907.

and the Home Office have no connection?—I know that they are all under the Act.

11136. Under the Act—yes?—I suppose there is no connection under the Act. There is no connection in that sense.

11137. There is no connection whatever. Therefore, you do not hold the Home Office responsible for what is done under the Irish Government?—I am very glad to acquit you, Sir Mackenzie, of Professor Shaw. When I brought that forward, I was not bringing it forward as an attack on the Home Office.

11138. I only asked, because, as you would say, unfortunately, from your point of view, both the Home Office and the Irish Office take the same unfortunate view of their duties under the Act?—In that case they certainly did take the same unfortunate view. I think in that case, as a matter of fact, the six months' limit prevented the Home Office from doing anything. I do not think the Home Office knew about these experiments until we drew their attention to them.

11139. The Irish Office, if you please?—Yes. At that time the six months was out, and I do not think they could have done anything with the best will in the world. I think they said so in their letter to me. I am only judging by memory now.

11140. (*Mr. Ram.*) With regard to your attitude generally, as I understand, your attitude and that of your Society is one of regulating the practice of vivisection as much as you possibly can?—Yes.

11141. That, of course, is a view that we can appreciate and sympathise with much more than with some views which others have given us. With regard to that, your Bill, which I will deal with in a moment, proposes certain alterations of the existing law with that view?—Yes, with that view.

11142. With regard to the past, the present Act is 30 years old, and the law has been administered under that Act for that length of time?—Yes.

11143. Your Society is older even than that?—About contemporaneous; two months before, I think.

11144. And your Society, no doubt, during the whole of that time has been composed of persons active and anxious in every possible way to repress any cruelty or stop any illegality?—Certainly.

11145. Under the Act the powers granted to private persons to put the law in operation are found in Section 13, under which a person may apply to a Justice of the Peace if he believes that any act has been performed by an unlicensed person in any place not registered under the Act. Has any application ever been Section 13, under which a person may apply to a justice for such warrant to examine any premises under that section?—Not that I am aware of.

11146. Has an application ever been made under Section 21 to the Secretary of State to allow a prosecution against a licensed person who has been doing an experiment for any reason other than that allowed by the Act?—Not since I have been honorary secretary, certainly.

11147. Is that because you have never had any case which, in your opinion, would justify such a request being made?—Oh, no, it is because under the way in which the Act is administered, and within the four corners of the Act, it is impossible for us to find out what happens inside the laboratories.

11148. Let me sever the two things for a moment, under the Act and under the administration; I am coming to the administration shortly. Under the Act you say that you have never been able to ascertain any instance which would have warranted anyone on your behalf making an application for a prosecution?—I do not think I have ever known of any instance, which I thought was a breach of the law, which was published until after six months.

11149. Therefore there has never been any such application made?—No.

11150. With regard to publication being made six months afterwards, you have given us a list of five or six different cases in which there has been, in your opinion, a breach of the Act, and as to which you have found fault with the action of the Home Office; those are the cases that you gave us in your evidence the time before last. You will recognise them by name. There is Crile's case, Grünbaum's case, Starling and Bayliss' case, Cecil Shaw's case, Noel Paton's case, and Dixon and Brodie's case?—Yes.

11151. Those are the cases which you gave?—Yes.

11152. With regard to those cases, you believe that there has been some contravention of the Act?—I should like to look at each case. The *gravamen* of my attack is that in each case when I have complained to the Home Office of actions done which seem to me to be inhumane, the Home Office have accepted the *ipse dixit* of the person whose conduct was impugned. It may not necessarily have been a breach of the Act.

11153. I think in each of those cases you did allege that there had been a breach of the Act, and you called the attention of the Home Office to it?—If you would give me them one by one, I can answer you.

11154. Crile's case was the case in which you said that there was an operation performed under incomplete anæsthesia?—Yes.

11155. That would have been a breach of the Act?—In that case pain was inflicted under the licence.

11156. Yes?—I should say that that was a breach of the Act.

11157. In Grünbaum's case, he performed an experiment, as you allege, before the public?—Yes.

11158. In Starling and Bayliss' case we do not doubt that there was an allegation of illegality?—Yes.

11159. And that was established largely—I mean the allegation?—I ought to distinguish now. My assertion is now that Professor Starling broke the Act by not killing the "brown dog" before he gave it over to Mr. Bayliss. That has never been before the court.

11160. I quite gather that. In Dr. Cecil Shaw's case it was an alleged breach of the law; that is "my work"?—Yes.

11161. Then Dr. Noel Paton's was the case of fasting experiments?—Yes. There is a little distinction in the case of Professor Noel Paton. Professor Noel Paton asserted that these experiments were outside the Act.

11162. Quite so?—That is not a breach of the Act. His defence was that they were outside the Act, and I represented that they should be within the Act.

11163. And Dixon and Brodie's case was a case of incomplete anæsthesia?—Light anæsthesia.

11164. Those are the cases that you brought before us?—Yes.

11165. Were those all the cases that you reported to the Home Office as having been, in your opinion, contraventions of the Act?—I could not say that.

11166. At all events, they are all that you have brought before this Commission?—Yes.

11167. In all or in any of those cases, do you allege that any suffering was caused to the animal by reason of the alleged breach of the Act?—Yes.

11168. In which case?—In Dr. Crile's case, for instance, certainly.

11169. Dr. Crile's was a case of incomplete anæsthesia?—Yes.

11170. You are aware that in that case, whether the animal suffered pain, turns upon whether the anæsthesia was or was not complete to the extent of removing all such pain?—Yes.

11171. And if, as Dr. Crile asserted, and as the bystanders seem to have asserted, the animal was insensible to any feeling of pain, then there would be no pain caused by a breach of the Act?—If they were accurate.

11172. With regard to any other cases, do you allege suffering being caused by an alleged breach of the Act?—Most decidedly to the case in Ireland—shoving shot into a rabbit's eye and watching it for six months.

11173. The Irish case I have purposely avoided; I was dealing with the cases reported by you to the Home Office?—In Dr. Noel Paton's case, of course, I assert that to starve an animal for four days is a painful thing.

11174. Eliminating the case of Dr. Noel Paton for a moment, as to starvation, are there any other cases in which the alleged breach of the Act involves suffering to the animals?—You want to know which of those cases are both illegal and painful?

11175. Yes?—If you will rehearse them again, I should like to have them separately. I have answered as to Crile and Noel Paton.

11176. And as to Grünbaum?—Yes, Grünbaum's experiments certainly were painful.

11177. In what way were they painful?—He describes the rabbit after 30 minutes dying in convulsions of snake poison.

11178. In that case the animals were being legally operated upon under the Act, save in so far as the operation was public?—Yes, but you ask me whether they were painful, and I say that they were.

11179. What I put to you was whether the illegality increased the pain?—No, not the illegality.

11180. Then I think it comes to this, that except in the case of Dr. Noel Paton starving animals, the illegality did not cause pain to the animals—did not cause any increase of pain?—You mean, if you accept the defences?

11181. Yes?—That is so, if you accept the defences.

11182. May I take it that in all the years during which your Society has been investigating these matters, those are really all the cases, as to which you have brought before the Home Office allegations of impropriety or contravention of the Act?—I am not prepared to say that. I have brought forward a few of them. I do not think I could say that I have brought them all.

11183. Would you let us have any others which you consider important. I take it that even if these are not all, you brought before this Commission those which you regard as the most serious?—I have got instances, which, to my lay mind, seem to involve a great deal of suffering, but not illegality.

11184. I am pointing out that these are the only matters which you have brought to the notice of the Home Office as being illegal?—Possibly. I am not prepared to say that offhand. I have only brought a few of the cases.

11185. But you have brought, no doubt, the cases which seem to you the most important. You have not given us the worst of your cases.

11186. (*Chairman.*) Was it your intention, in going through them, to bring before us all the cases in which there was illegality?—I am constantly corresponding with the Home Office, I am sorry to say.

11187. If you say that it was not your intention, that is an answer?—I am not prepared to say that these are the only cases in which I complained of illegality.

11188. That was not the question. Are there others in which you complained of illegality?—I think very likely.

11189. Do you know of any others?—I have a very bad memory. I cannot say offhand. Sir Mackenzie Chalmers would be able to say.

(*Sir Mackenzie Chalmers.*) I quite agree that you did write about others; but these are like the strawberries—the best at the top.

11190. (*Mr. Ram.*) We can only deal with those that you have put before us. Everyone of these matters was, in your opinion, and in the absence of explanation, a technical breach of the Act?—Yes.

11191. With regard to the case of the chemists, your allegation there is that there was an illegality, because the experiment was performed before an Association of Chemists, which constituted the public?—Yes.

11192. You have been asked whether you had ever witnessed an experiment yourself, and you said No, that you would not assist the physiological experimenters in breaking the law?—That is so.

11193. Do you think it would be an advisable thing, in the interests of humanity, if some such person as yourself, say, who takes an interest in humanity, did witness some of these experiments from time to time?—Most certainly.

11194. Have you been precluded from doing that in the past by the Act?—Yes.

11194A. You think that it would have been a breach of the Act?—Yes.

11195. Let me refer you to the part of the Act which deals with that matter. It is Section 6, the words are: "Any exhibition to the general public, whether admitted on payment of money or gratuitously, of experiments on living animals calculated to give pain shall be illegal." Do you think that when you are finding fault with an experimenter, if he said to you "Come and see what I do," which I understand is what you have been asked?—I have been asked.

11196. In your opinion would it be a breach of the Act if you, as one of the public, went to see it?—Yes. I have always thought so.

11197. You do not arrogate to yourself that you are the general public?—I am one of the public.

11198. (*Chairman.*) The question is, whether it would be a breach of the Act on the part of the operator if he allowed it?—Yes.

11199. (*Mr. Ram.*) But you said that you would not assist him in that breach?—Yes, I feel that I should be assisting him in that breach.

11200. I can understand it, but I cannot agree with it. May I put it to you in this way, that if you had gone you might have done infinite good from the point of view of humanity?—I do not think that any animal would be subjected to torture in my presence by any vivisector. That is why I want the Inspector always present. My presence would have the same effect, I think, as the presence of a Government Inspector.

11201. At any rate, you would have known much more about what was done in these experiments if you had been present?—Yes.

11202. But I understand that that was your reason, and the only one?—If I was present they would know that I was present.

11203. May I ask whether, had it not been for this section of the Act you would have gone?—I do not think that I should have served any general purpose by going, unless I had a right to go when I liked. To go by invitation would mean nothing. Of course, I should see no infliction of pain on an animal, being a more or less well known anti-vivisectionist.

11204. You would have learned a great deal of the circumstances under which experiments took place?—No doubt.

11205. Your evidence, which I have gone very carefully through, is something like, I may say nine-tenths of it, an indictment, and a long and acrid indictment, not of the Act but of the administration of the Act by the Home Office?—And of the Act also.

11206. I leave one-tenth to the Act?—Yes.

11207. There is an indictment with twelve different counts against the administration of the Act by the Home Office?—Yes.

11208. In your Bill you also propose that licences should be granted by the Home Office and the inspectors appointed by the Home Office and so forth?—Yes, I leave some of the Act of 1876 alone.

11209. But I think you leave all of it, so far as that goes. You safeguard it when they are appointed, but you leave their appointment to the Secretary of State?—Yes.

11210. The same Secretary of State whom time after time, man after man, you have distrusted so much in the past?—First of all in my Bill the certificates would not be merely as to the scientific fitness of the applicants, but also as to their humanity.

11211. I am coming to that afterwards?—And secondly, of course, the mass of operations will be performed in the presence of the Government Inspector.

11212. I am coming to that also. In the meantime the appointment and administration must, as you put it in your own Bill, be under the Home Secretary?—Yes.

11213. Now with regard to the certificate of humanity which you ask for in the eighth clause of your Bill, do you really attach importance to that?—Yes, very great importance; always provided that the names of those who sign the certificates are published.

11214. You will exclude, I suppose, any person who avowedly did not love animals?—Oh dear me no, I only want a person not to be unmerciful.

11215. I want, if I can, to get at something tangible. You want a certificate of a Justice of the Peace, or a Minister of Religion, for instance, that a person is humane?—Yes, that he is a person who would not torture an animal.

11216. There are a great many Justices of the Peace and Ministers of Religion. Should you really attach importance to two Ministers of Religion or two Justices of the Peace having signed a paper to say that they

The Hon. S. Coleridge.

3 July 1907.

believed that the applicant was a humane person who would not torture an animal?—I should if their names were published, so that they were publicly made responsible.

11217. You suggested, I think, in answer to one question put to you by Sir Mackenzie Chalmers, that your own Society would be a useful body to give those certificates of humanity?—I did not say that; you are putting that into my mouth.

11218. If it was said *per incuriam*?—I should have put it in my Bill if I had thought it proper.

11219. Do you suggest that it would be a good thing?—I think that my Society is quite as fitted to advise on humanity as that other society is to advise on scientific fitness.

11220. Do you know and can you name any experimenter whom you would consider humane?—Yes, I believe there are some vivisectors who are quite humane, and if it was my duty to find out who were humane, I should do my very best to ascertain it.

11221. And the statements of such men as that you would take as being accurate statements when they were asked what they meant?—Yes, if I was satisfied that they are humane.

11222. Then may I take it that you regard untrustworthiness and, to a certain extent, unveracity and inhumanity as being almost identical?—I do not quite say that. I say that if a man is inhumane and is then asked questions by the Home Office or by any authority as to what he has done, if he has been inhumane it is contrary to human nature for him to admit it. No man would in that case. If a man is inhumane he is driven, if he is asked what he has done, into a certain amount of inaccuracy no doubt.

11223. I do not quite follow that. Sometimes even dishonest prisoners plead guilty?—No doubt.

11224. (*Chairman.*) The certificate is not to be that the Justice of the Peace knows that he is humane, but knows that he has a reputation for humanity?—Yes.

11225. (*Mr. Ram.*) How does a man get a reputation for humanity?—That is as near as I can get it.

11226. I am only anxious to know how much importance you really attach to that?—I attach very large importance to the fact that these persons who, by signing, more or less undertake in the public eye that these men are humane men, should have their names published so that everybody should know who they are. It is a responsibility which a man will not lightly take upon himself unless he is quite sure.

11227. There are two or three detached questions which I want to put to you with regard to your evidence. In answer to Question 10517 you said that you take no interest in the object with which any experiment is made?—That is broadly my attitude.

11228. You said it once or twice; you used those words?—Officially I mean to say that my Society is interested absolutely from the point of view of the animal.

11229. But you do recognise, because I see that you put it in your Bill, very wisely I think, in Clause 2, Sub-section (1), that "the experiment must be performed with a view to the advancement by new discovery of physiological knowledge or of knowledge which will be useful for saving or prolonging life or alleviating suffering?"—That is in the old Act. I leave that.

11230. But you recognise there and you perpetuate, of course, naturally, that these experiments must have a humane object in view?—What I meant was, I may have been misunderstood, that when there is a question of severe pain, my Society does not recognise any justification of that pain by any lofty motive being asserted.

11231. I am glad you have answered the question, and I am glad to have that explanation. I want you now to look at your Bill, please, on two or three points. You say in Clause 2, Sub-section (4), "The animal must be killed while it is so under the influence of such general anæsthetic as aforesaid, and before it recovers therefrom sufficiently to feel pain." Is it your object to preclude all operations which, while painful in the inception, and therefore necessarily requiring an anæsthetic to be administered while they are being performed, are of such a nature that the result cannot be ascertained unless the animal be allowed to recover?—Yes.

11232. Then you wholly obliterate Certificate B and all cases under it?—That is our desire.

11233. That is your object?—Yes, we believe that under Certificate B most severe pain is inflicted.

11234. You do contemplate, and under your Bill you allow, the perpetuation of experiments not calculated to give pain at the initial stage?—Yes, those inoculations.

11235. But which may produce pain afterwards as the result of the inoculation?—Yes.

11236. Supposing that an animal has an operation performed upon it under anæsthetics, and is allowed to recover, and is treated, as we have been told here, as carefully with antiseptics, and generally treated as a human creature would be, so that there cannot be anything like severe suffering, do you think it is more objectionable to keep the animal alive under those circumstances than to allow the animal to live for a certain time, at any rate, while suffering from the effects of inoculation?—Under my Bill the moment the animal displays any sign of severe pain it is to be destroyed.

11237. I am coming to that in a moment. I quite see that that is your point. If the animal operated upon under anæsthetics and allowed to recover, making recovery under antiseptic treatment, was plainly not suffering severe pain, would you have any objection to allowing it to live?—It all depends upon the statement that the animal is not suffering.

11238. It does?—We are not prepared to accept absolutely the statement that all operations, however severe, leave no suffering behind.

11239. There has been no such statement made before this Commission or anything like it. The statements made before the Commission have been that in many of these cases, although the operation was painful, and therefore demanded anæsthetics in the performance of it, there was no subsequent suffering at all. But you say that you are not prepared to accept that statement?—I am not prepared to accept it.

11240. But under your Bill you provide that the Inspector should often see such animals, in the last sub-section of Clause 2, and that the animal is to be killed if suffering?—Yes.

11241. My object is to see how far your Bill would help us. Would it not be sufficient, in your opinion, to allow such operations as I am now indicating, the animal recovering, if the Inspector who saw the animal repeatedly satisfied himself that it was not suffering, or, if it did suffer, caused it to be killed?—I think that is outside.

11242. You see, my anxiety is this: You have said yourself repeatedly, and that is what has made your evidence, I think, on many points valuable, that you do not want to stop research?—That is so. We are quite misunderstood if anybody thinks that we want to stop science. We wish to promote science.

11243. You would wish, therefore, to make such provisions as, while safeguarding the animal, will secure the continuance of research?—Yes.

11244. I may take it, then, that you agree with me that if the Inspector sees the animals and certifies that they are not suffering, or causes them to be killed, if they do show signs of severe suffering, there might be operations under what we call Certificate B for short, which still might be permitted?—Yes, with this proviso. We are now talking of Certificate B, and under the present law my contention is that long before that period to which you now allude when the animal is healed——

11245. Not healed?—Is healing; and long before that under Certificate B, as now worded, atrocious suffering, in our opinion, can be inflicted upon it.

11246. At the moment I am on this point, whether you can suggest such a modification or, in your view, such an addition to Certificate B as will grant its existence in future, although perhaps modified in the way that you yourself wish?—If Certificate B could be so framed as to preclude such experiments as I have instanced of Mr. Stewart's—I am not agreeing for a moment with the description of Mr. Stewart's operation—it might be that the animal was under curare, for I do not know how many hours, and nothing else. It is such experiments as those that I am aiming at destroying in this Bill.

(*Dr. Gaskell.*) Those operations are under licence, not under Certificate B.

11247. (*Mr. Ram.*) That does not touch the point in one sense, but I want to follow this point. If you obliterate Certificate B altogether you do prevent an enormous number of investigations, the results of which cannot be ascertained, unless the animal is allowed to live for some time?—Yes, it must be so.

11248. And those operations, so far as this Commission has been instructed, seem to be the bulk of the operations which in the past have thrown most light upon the different humane objects which it has been desired to carry out. You accept that?—I accept that you have been told so.

11249. Then what I am anxious to get you to assist me in, if I can, is some such alteration or modification in Certificate B, as in your opinion might make it safe to allow it to continue safeguarded, rather than put a stop to all the investigations which at present can take place only under Certificate B?—Of course we are very suspicious of Certificate B, and it is very difficult for me, as representing my society, to say. I should only agree to its being continued provided that the animal after the operation is as much safeguarded as it would be under inoculation.

11250. That is the very point I wanted to bring out. Now with regard to inspectors, you, I suppose, realise that you are asking one of two things, either for an army of inspectors or for a very great diminution in the number of experiments that will take place?—Not so, necessarily. At present the Inspector, as I have said, wanders about on the chance of seeing anything, and wastes an enormous amount of time in that way. If every experiment had to be performed before an inspector he would never waste a minute; he would go from one place to another and witness experiments, and all his time would be occupied in actually seeing experiments, instead of wandering about the country seeing nothing as now.

11251. At all events I gather that there should be an inspector present at every physiological experiment?—Yes, but there are not so very many. If you leave out the inoculations the number is not very large.

11252. (*Chairman.*) Upon that point would it satisfy you if, instead of the operator being forbidden to perform an experiment unless the Inspector was there, a notice was given always beforehand that an operation would be performed at such and such a laboratory of such and such a kind; because there might be some purely insignificant operation which the Inspector need not attend. At any rate, there would always be knowledge on the part of the Inspector that it was going to be done at a particular time, and the operator might expect to see him coming in at any minute, but at the same time he might not be there in every case. For him to be there in every case would seem to me a tremendous interference?—We view it from the point of view of the animal. We feel that the animal is entitled to the presence of the Inspector when it is subjected to a severe operation, whatever it may be.

11253. A notice would not meet your view?—No.

11254. (*Dr. Gaskell.*) Do you mean that you would not allow more than one experiment to be made in a laboratory at the same time. There are often three or four experiments going on?—Do you mean in one room?

11255. No, in one laboratory?—Certainly not.

11256. You would not allow that?—No, I think that the Inspector should be present at every severe physiological experiment on an animal. He might go from one room to another.

11257. (*Chairman.*) You do not say severe in your Bill?—I mean any physiological experiment.

11258. You do not mean to include every inoculation?—No.

11259. Or every operation for which a licence was necessary?—No, a licence is necessary for inoculations.

11260. You mean any operations for which anæsthetics are necessary?—Any operations for which anæsthetics are necessary, certainly, because the presence of an anæsthetic means suffering, and therefore whenever there is suffering or the chance of suffering, our opinion is that the inspector should be present.

11261. (*Mr. Ram.*) While we are on the question of suffering I think you want some modification of your Bill at the bottom of page 2. In the last two lines you provide that the animal may be allowed to recover, although inoculated, and you say, "Directly the animal begins to feel pain it must be placed, and thenceforth while it suffers or is likely to suffer must be kept under the influence of a general anæsthetic of the nature of a respirable drug or gas, such as chloroform, or ether, or alcohol, chloroform, and ether combined, of sufficient power to prevent the animal feeling pain; or, if the animal is not so placed and kept under the influence of such anæsthetic as aforesaid, it must be forthwith killed"?—Yes.

The Hon. S. Coleridge.

3 July 1907.

11262. But in your evidence I observe that you say, and you have said just now, severe pain; you mean, I take it, appreciable pain?—I am not unreasonable. There is no pain gauge that I know of.

11263. You have said repeatedly, and said reasonably enough, in your evidence, for instance, in answer to Question 10765: "It will be the duty of the Inspector to go and see that animal frequently, and if it be in a severe condition of suffering it will be his duty to order it to be killed painlessly"?—Yes.

11264. You must therefore in your Bill modify that?—Where the suffering is really trifling, of course, I do not want to interfere.

11265. But you see we are or may be advising legislation here, and I want to see whether you can assist us in any way?—May I say serious pain.

11266. You would be willing to insert "serious pain" in line 36 at the bottom of page 2 of your Bill?—Yes.

11267. You have put it so clearly in your evidence in reply to Question 1078: "It depends entirely upon the amount of pain involved," and in the next answer, "Under my Bill it would be the duty of the Inspector to have that animal destroyed as soon as it manifested signs of severe suffering"?—Yes.

11268. That is what several Inspectors who have come before us here have said in answer to myself and others, that as soon as they saw any signs of appreciable suffering they would cause the animal to be destroyed. With regard to Clause 3 of your Bill—I remember the experiment which you told us of about the eye—do you think it is necessary to have a clause dealing with the eye expressly?—There is a very large feeling among the humane that it is a necessary clause in the Bill, because the eye is so frequently used, I believe, for the purpose of breeding bacteria and such things. That is the ground upon which we put it; and the eye is a very sensitive organ.

11269. Is it suggested that now in England matters which cause pain are inserted into the eye of anæsthetised animals?—I think so. I have seen pictures of diseased eyes.

11270. Would it meet your view to say that no operation of any sort shall be performed on the eye, save when the animal is under anæsthetics?—That would be so already. The eye is not put outside the Act. If an operation is performed on the eye it is as much under the Act as if it is performed anywhere else.

11271. I wanted to see whether you still think it necessary to except the eye from any experiment at all?—From inoculations we think that they should be eliminated altogether. Our view is that inoculations in the eye must always be painful—we may be wrong.

11272. Under Clause 4, Sub-section (2), you provide that every licence shall specify the time and place at which the experiment or series of experiments is or are to be performed. Is that with the object of letting the Inspector know?—Yes, and the public and everybody else; to lift up the veil of secrecy from these things.

11273. We have heard something about the veil of secrecy; but why on earth should the public know when an operation takes place?—Because this is part of the thing that is put up; this is part of the notice. It is the licensee who is to say when he is going to do it.

11274. I ask why?—In order that the Inspector may know.

11275. Then you eliminate the public?—Yes; I was not looking at it. "Every licence granted hereunder

The Hon. S. Coleridge.

3 July 1907.

shall specify the time and place at which the experiment or series of experiments is or are to be performed." That is in order that the Inspector may know for certain when it is going to be performed. I was thinking, and no doubt you were, of the putting up of the notice somewhere.

11276. I was. One other question on the Bill, and, I think, only one. You propose in Clause 9 that proceedings may be taken at any time within two years?—Yes.

11277. And yet you propose that a report shall be sent in forthwith?—Yes.

11278. If a report is sent in forthwith, how can it be necessary to have so long a time as two years within which to take proceedings?—I put both those conditions in, so as to get the longest possible time.

11279. May I point out that the object of shortening the time, as you know, in all these Acts is to preclude a charge being made against a person, when perhaps the circumstances are forgotten, or the evidence is lost, or some person is dead?—I thought that would be met by the provision that the prosecutor shall put down the sum of £50.

11280. Would that affect your Society, with its large income?—We should be the last persons to bring an action.

11281. (*Chairman.*) This is a question of instituting a prosecution?—Yes.

11282. (*Mr. Ram.*) Seriously now, supposing you got your way in having a report sent in forthwith, as to which we should want a definition, I think, but, say, within fourteen days, would you want so long a time as two years?—Perhaps that report might have omissions which might be supplied in a subsequent publication by the vivisector.

11283. You would have five and a half months, then?—That would depend upon when the vivisector published it. In the report sent to the Home Office, it is conceivable that the vivisector might leave out something accidentally or intentionally, and might subsequently fill it in in a publication like the "Journal of Physiology."

11284. Would it be sufficient to say that any proceedings must be taken within six months of publication, or giving information of that which was impugned?—Yes, I would accept that at once. All we want is that we may have the possibility of doing it.

11285. What I want to get rid of is the oppressiveness of these proceedings hanging over for two years?—I accept that at once.

11286. There is one matter I should like to have your view upon, because you are aware that statements have been made which have been investigated before us in the "Shambles of Science"?—I have read the book some time ago.

11287. I wanted to ask you about that experiment on a marmot?—I cannot tax my memory with that.

11288. Then I do not think I will go into it at all?—I am not connected with that book in any way.

11289. There is one other point in your Bill. In Sub-section (6) of Clause 2 you say, "The experiment shall not be performed for the purpose of attaining manual skill"?—Yes, that is the old Act; I retain that.

11290. A good deal has been said about it; do you see any objection if it is limited to animals which are wholly under anæsthetics, and must die under anæsthetics?—It is hardly for me to suggest to the Commissioners to enlarge the Act.

11291. But you know so much about it, that I wanted to know your view. Have you considered that point?—Yes, I have. Personally, I am afraid that if this provision was taken out, it would immediately be taken to be a permission to students at once to set about vivisection for the purpose of getting manual skill.

11292. By a licence?—Yes, getting a licence for this very thing.

11293. Students?—Yes. Certainly they would if this clause was eliminated; there is nothing to prevent their applying for a licence for that very purpose, to get manual skill.

11294. You do not suggest that taking these words out would give them permission?—No, I say that they would apply for licences, and would get them from the Home Office. I believe that they get them now.

11295. There is one other matter only that I want to put to you. Several witnesses have been asked, but I do not think that you have, and I put the question to you, does your Society take any action at all, or any interest, in what has been termed a farmyard operation—namely, castration, and so forth, of animals?—My Society does not. It is a Society simply for the purpose of combating vivisection.

11296. Has your Society, or have you as an individual, any views as to the thousands of operations in every county in England, which must, I think, every day cause more pain than all the operations in all the laboratories?—No, my Society has no such view, of course. It is purely an Anti-Vivisection Society. If I were to use its funds for the purpose of advocating a crusade against any other suggested form of cruelty, I should be committing a breach of trust.

11297. Your Society, then, not only concerns itself with vivisection alone, but solely concerns itself with vivisection which is scientific?—With vivisection under the Act.

11298. Of course, all these operations are vivisection in the crudest and cruellest form?—If so, they come under the purview of the Royal Society for the Prevention of Cruelty to Animals. That is our view. That is the proper society to deal with any such cases.

11299. At any rate, your Society does not concern itself with that matter?—It is outside our Society.

11300. I think you have been careful to abstain from going into any of what are called the ethical considerations?—No, the whole of my evidence has been in that direction. I stated that I threw myself open to cross-examination.

11301. (*Chairman.*) I invited Mr. Coleridge at the beginning to express his views shortly on that point, as we have had it fully before us, and he agreed to that. He stated shortly that he was opposed to vivisection on ethical grounds.

(*Witness.*) Yes, in my opening statement.

(*Mr. Ram.*) Perhaps I misread what the noble Chairman put to you; but, at any rate, I will not go into it with you, your evidence having been of another sort.

11302. (*Sir John McFadyean.*) I am afraid that after a remark that fell from you in answer to a previous question, you may rather resent the suggestion that you ever use any language that is ambiguous; but it seemed to me that you did in your evidence make use of two or three words that are capable of more than one interpretation. One of them is the word torture. I submit to you that the word torture is employed in two senses. In the first place, it is employed to denote very severe pain, and in the second place it is employed in describing operations and acts where the main object of the operation or act is to cause severe pain. I want to ask you in which of these senses you use the word torture. For instance, to-day you said that in your opinion animals are tortured in laboratories attached to large hospitals. Do you mean simply that in vivisection operations conducted in these laboratories severe pain is occasioned to animals?—That is what I mean.

11303. That is all?—That is all.

11304. You did not mean at all to imply that it was the main purpose of the operation to inflict pain?—I was not thinking of the purpose. I am looking at it entirely from the point of view of the animal.

11305. I am asking you now because it is a very important distinction; that is to say, whether you merely make the charge that severe pain is occasioned to animals?—That is all.

11306. You do not mean that it is a deliberate design on the part of the operator to cause severe pain?—No; it is incidental to the investigation.

11307. Still, you admit that the word "torture" is used in both senses?—It may be used in many senses. That is not my intention at all.

11308. Then you make use of the word "cruelty"?—Yes.

11309. I do not know whether you admit that that is in any degree ambiguous?—I will define cruelty in the way I use the word.

11310. Will you tell the Commission what your de-

finition is?—When I say "cruelty," I mean the infliction of severe pain upon an animal, not for its own good. It is very difficult to define these words.

11311. It is not quite the definition that I expected?—That is what I mean.

11312. I thought you would probably say that all unnecessary pain comes under the head of cruelty?—No; that would imply that I judged what was necessary and what was not necessary for the purposes of experiment, of which I know nothing.

11313. But your definition does involve your judging the question, because you come to the conclusion that it is cruelty in all cases in which pain is inflicted, if it is not for the animal's good?—Yes.

11314. I am quite content with that definition. You will, I suppose, admit that the Act now in operation, the Act 39 and 40 Victoria, was not meant to prohibit painful experiments on animals, but merely to place certain restrictions on such experiments?—The Act as it left Parliament.

11315. That was the purpose of the Act?—Yes, it permits pain.

11316. It legalises pain?—It legalises pain; that is my objection to it.

11317. Your suggested amendment of this Act is intended to prevent the infliction of serious pain?—That is so.

11318. Or even serious discomfort?—Utter wretchedness.

11319. In connection with experiments on animals?—Yes.

11320. You wish to make it illegal to cause serious discomfort to the animal, even although, in the opinion of persons well qualfied to judge, the experiment might extend man's knowledge of preventing or curing disease or alleviating suffering?—I am not prepared to accept or admit, not being an expert, the claims put forward by the vivisectors as to those benefits.

11321. That I did not put to you. I asked you to assume that?—That there is benefit, do you mean?

11322. To assume that man's knowledge may be increased thereby?—That is a different question.

11323. Knowledge is power?—But the Act itself divides between the two, you remember; it says for benefit or for knowledge. There are two objects in the Act.

11324. Is it, or is it not, the purpose of your amendments to prevent the infliction of serious pain or even serious discomfort?—Serious pain.

11325. You admit that?—Yes.

11326. And you desire to have the infliction of serious pain or serious discomfort made illegal, even although, in the opinion of persons well qualified to judge, by carrying out experiments involving such pain, man's power of preventing or curing disease or alleviating suffering might be extended?—The evidence laid before the Commission has been almost unanimous in declaring that vivisection and experiments performed do not include pain.

11327. But I assure you that that has not been the invariable character of the evidence that we have had here, and I think it is within our own knowledge, as Commissioners, that some experiments involve pain at the outset. I have asked you to agree to the statement that the Act legalises pain?—Yes.

11328-9. Therefore, there is no reason why those who are licensees should not admit that they do cause pain. But I put it in another way. You do not admit that the fact that useful knowledge might be extended by inflicting pain on animals, with regard to the cure and preventing of disease, is any justification whatever for causing pain to animals?—No. I say that we have no right to inflict severe pain upon animals.

11330. I perfectly understand your position. My next point is this. You are, I suppose, quite well aware that no such restrictions as you propose to impose upon experiments performed on animals for the purpose of extending human knowledge are placed on man's dealings with animals for other purposes, although these involve severe pain and suffering?—I am not prepared to admit that.

11331. I shall have no trouble in getting you to admit it?—Very well.

11332. Will you take it from me that it is perfectly legal, and a common operation, to take a male animal, tie it to a table, or otherwise secure it for the safety of the operator, and while it is in complete consciousness cut out its testicles? As a laymen, do you feel able to express an opinion as to whether that is a painful operation or not?—I have no doubt that it is painful.

11333. Have you any doubt as to its being an exceedingly common operation?—I have no doubt it is quite common.

11334. I suppose you are also aware that it is not regarded as an illegal operation?—I do not know that there has ever been a test case on that. I think it is cruelty to animals generally.

11335. Then I will put it to you in this way. Would you encourage the creation of a society, such as your own, having for its main object to bring about legislation to prevent the castration of male animals?—I do not say that.

11336. But you admit that it is cruel?—Yes.

11337. Would you, then, be in favour of an agitation which would compel the use of an anæsthetic pushed to complete anæsthesia on every farm animal that is castrated?—Yes, if it was practicable, certainly.

11338. Then, take your own words, what is the meaning of practically? Does it take into consideration the profit of farmers?—I am not thinking of that for a moment. I am thinking of it purely from the point of view of the animal and cruelty.

11339. Quite irrespective of the fact whether you would render farming operations, so far as relates to the breeding of male sheep, for instance, entirely unprofitable?—I do not accept that suggestion for a moment.

11340. It is not a suggestion; it is a question?—You suggest that it would make it unprofitable. I do not accept the suggestion.

11341. I ask you to assume that it would?—I will assume it, for the sake of argument. What next?

11342. You would still insist upon every male animal that had to be castrated being put under anæsthetics?—Certainly, but I do not accept the premise, you know.

11343. I did not ask you to accept the premise. But what I asked you to assent to was that at the present time such restriction as you seek to impose in your Bill are not imposed on men in other dealings with animals which involve great pain?—I may, in passing, say that so far as I know there is no Act of Parliament that makes it cruel, or would in any way support a prosecution for the circumcision of Jews, which is, I suppose, a painful operation, but it is done in very extreme youth, and it is quickly over, and it is done, I presume, for some purpose that the Jews support. It is somewhat similar to that, I think.

11344. Will you forgive me for suggesting that one might, at any rate, contend that it is done for the benefit of the individual Jew operated upon?—Yes. Whether it is so or not I am not prepared to say.

11345. You would not seriously put that forward with regard to castration of lambs and pigs?—The castration of lambs and pigs I presume is inflicted for their benefit; they would not be permitted to live unless it was done to them.

11346. Do you suggest the same with regard to horses?—Yes.

11347. Are you not aware that in some countries a very large proportion of the working horses are uncastrated?—If that be so, and there is no reason against it, I am in favour of their not being castrated here. But I have always understood that they would be dangerous in the streets.

11348. I think it is unquestionable that they are more dangerous, but not to the point of being unworkable?—Then we should have to do without them, I suppose.

11349. You would be in favour of a society which would agitate for the suppression of the castration of horses?—I did not say that. I never said it.

11350. But I think you must say so in order to be perfectly logical?—No, I say that it should be painlessly done.

The Hon. S. Coleridge. 3 July 1907.

11351. I will give you another example of man's dealings with animals in which severe pain is caused, and up to now, so far as I know, no restriction has been placed on these operations. Take, for instance, the trapping of rats and rabbits. I suppose you will admit that these are operations which cause pain which, without exaggeration, might be described as torture to the trapped animal?—That depends upon the sort of trap, does it not?

11352. I am speaking of the common rabbit trap. I only know the humane trap by name. I am well aware that the common trap is an exceedingly painful trap, which very often breaks the leg, and the animal may be in a state of torture for many hours?—I abominate that.

11353. It is not a case of your individual opinion?—I thought that was what you asked.

11354. I mention all that in order to lead up to this. It is not the individual feelings and actions of witnesses that have to be justified?—Are you asking me as representing my Society?

11355. No. You want this Commission, I take it, to approve of your Bill?—I do.

11356. Nothing would please you more than that we should recommend Parliament to pass it?—I should be still better pleased if you abolished vivisection altogether. I am afraid you will not do that.

11357. I am looking forward to the possibility of your Bill being recommended in Parliament, and I have foreseen that in Parliament these facts that I have just been bringing under your notice might be raised. I thought perhaps that you would help the Commission to find some clearly defined simple principle on which they could recommend Parliament to thus discriminate between painful experiments for the extension of useful knowledge, and the infliction of pain which is incidental to operations which are inspired by some other motives. So far we have not got that assistance from previous witnesses, except that some have said that no operation of a painful character on the lower animals is justified unless it is for the individual animal's good?—I would answer you in this way. I am not in Parliament unfortunately, but if I were in Parliament I should meet arguments of that nature, that you ought not to pass this Bill until some other cruelty was disposed of or dealt with, that you would never do anything in this world if you tolerated evil in one place until you stopped evil in another. If you must not stop a man beating his wife in Stepney until you have stopped another man jumping on his wife in Upper Tooting you would never do any good at all. You must take things in detail. You cannot put down all cruelty at once. The object of my Society is to deal with one branch of cruelty which we think very severe and which might be stopped with advantage to the community. It is no answer to us to say that there are other cruelties in the world. Of course there are. And in due course of time I should hope to see some of them mitigated.

11358. Would I be wrong in interpreting that answer as a confession that you find it impossible to state such a principle?—Not at all. The broad principle that I go upon is to put down all cruelty when I find it.

11359. I ask you if you could assist the Commission to find a principle on which they could ask Parliament to discriminate between painful experiments intended to extend man's knowledge and the infliction of pain in painful operations which are inspired by some other motives? I ask you if you can give us a simple principle?—No, I cannot put down a broad principle of that sort.

11360. Then I am afraid it is rather hopeless to ask Parliament to do so?—Not at all. I do not think persons in Parliament will be influenced by the argument that you are not to stop one cruelty until all cruelties are stopped.

11361. Would I be misjudging your reply if I took it to mean that as soon as you had disposed of this particular form of cruelty you would approve of going on to prevent the castration of animals except under the influence of anæsthetics, and that you would put down field sports, which, as you, I think, must admit, involve a great deal of infliction of pain?—Are you asking me now my own private views or the views of my Society?

11362. I will take both?—The views of my Society have nothing whatever to do with those other things.

11363. But, if you will pardon me, in a sense you have a great deal to do with them. You come here to advise us to take a particular course of action, and I think you will admit that we ought to be able to give a reason for advising Parliament to discriminate between pain which is inflicted in the course of operations intended to extend man's knowledge and pain inflicted in the course of operations inspired by any other motive whatever. Your Society ought, if it, I was going to say, presumes to advise us in the matter, to be able to help us in this case?—Our position is this, you see. These other cruelties that you justify have no Act of Parliament legalising them; they are open at the present moment so far to prosecution. It might not be successful, because public opinion may not have got up to the point at which such prosecution would be succuessful. But there is nothing on the Statute-book legalising these inflictions of pain that you are speaking of now.

11364. Would you be content to put what we call vivisection on the same footing exactly as these other operations?—No, because vivisection, in my opinion, under the present law certainly can be far greater cruelty than any of the cruelties you mention, because in the case of castration it is an operation that is done in a very few seconds, I presume; I do not suppose it takes a very long time, and some vivisections, at any rate, are very prolonged.

11365. I confess I am rather surprised that you should suggest that there are greater possibilities of cruelty in the one than in the other, because there are no legal restrictions whatever on the one?—Yes.

11366. You really, I take it, would not assert that the people who perform these operations on farm animals are on the average more humane than the licensed vivisectors?—In the very nature of things all the farmer wants to do is to get rid of the animal's testicles as quickly as he can. It must be a very short operation. With regard to the man in the laboratory, his object may entail a very long operation; the thing must take twenty to thirty minutes even to prepare the animal and the various vivisection arrangements and appliances.

11367. Are you taking into account that most of the seriously painful experiments at present performed for the extension of knowledge have to be done under anæsthetics?—Not under the Act as it stands necessarily. I say that the present law admits of any amount of torture. That is my objection to it.

11368. What I want to know is whether you contend that under the existing law a great deal of exceedingly severe pain is caused to animals?—I say it can be.

11369. That was not my question?—I dare say it is.

11369a. Do you say that it is?—I am not there. I will neither admit nor deny what goes on in laboratories. I am not there. All I know of what goes on in laboratories is what vivisectors choose of their own will to publish. That is all we know and can know of what goes on in laboratories.

11370. At any rate, you are not able to help the Commission by giving us any simple principle on which we could discriminate between painful experiments for the extension of useful knowledge and the infliction of pain which is incidental to operations which are inspired by some other motive?—I do not think any simple principle would discriminate.

11371. I quite agree with you. To pass to another point, the Act 39 and 40 Victoria legalises experiments for teaching purposes, and your amendment would make instruction in that way illegal?—Yes.

11372. In answer to a question put to you last week I think you grounded your objection to experiments for the purpose of teaching, on their being unedifying and bad?—Yes.

11373. Assuming that such experiments are painlessly conducted before medical students, will you tell us in what respect you think they are bad and unedifying?—You see you always put upon me an assumption that I do not grant.

11374. What is the assumption?—That there is no pain being inflicted upon the animals.

11375. I will allow the operation to be safeguarded by your own restriction that there is to be an inspector there the whole time. Will you tell the Commission then in what respect the operation would be un-

edifying and bad?—Because I think that vivisection of an animal not for its own good, merely for demonstrating some well-known principle of physiology, must be naturally approached by all the spectators in a perfectly different spirit from an operation upon a human being done for that human being's benefit. To me that is a perfectly self-evident proposition.

11376. But that should not be compared with operations on human beings. It ought to be compared with other legal painful operations on the lower animals. Is it less noble to use an animal in an absolutely painless fashion to demonstrate facts of physiology to a class than it is to kill an animal for food?—I thought the comparison was, certainly it was in my evidence, between a vivisection experiment in a laboratory and an operation in the theatre of a hospital.

11377. I never mentioned anything about that?—In my evidence that was the comparison put to me.

11378. You will forgive me if I am wrong, but so far as I could make out the only objection you have expressed to allowing painless vivisectional experiments to be performed for teaching purposes, was that they were unedifying?—Yes.

11379. I invite you to explain in what respect they are unedifying?—I am influenced very largely by the opinions of others upon the matter.

11380. By unedifying, do you mean that they are of no purpose, and are useless for the purpose of teaching?—I did not mean that. I meant by unedifying——

11381. Demoralising?—Yes, rather that. I did not use so strong a word. I used the word unedifying because I did not want to use such a strong word.

11382. I am sorry to repeat the question. Supposing the word to be used in its mildest legitimate sense, I want to know how it comes about that the operations are demoralising when the whole of the operations are painless and are known to be painless by the spectators?—I shelter myself under the opinion of others. The Inspector from Ireland gave that as his mature opinion after many years being Inspector. I do not know whether he used the word unedifying.

11383. I can assure you that he did not say they were unedifying. He expressed doubts whether they were of any real value, and he expressed a doubt as to whether they were always under complete anæsthetics. But I am going to have the experiment safeguarded by your Inspector. We were not able to put that to him.

11384. May I put it to you in this way. Do you see any reasons to modify your Bill by legalising operations for purposes of instruction when the Inspector is present and is assured that the animal is throughout the whole course of the proceedings completely anæsthetised. I may remind you that in answer to a question last time you said that you would place confidence in the opinion of the Inspector?—Yes. I am quite prepared to admit that at present I have no reason to suppose that any torture has ever been inflicted on an animal in the presence of the Inspector. That is why I am ready to trust the Inspector to see that it does not take place in future.

11385. Since the main purpose of your Bill is to prevent cruelty to animals (I mean you are not engaged in any religious crusade) why, if you were assured that these operations might be conducted without pain, should you expressly make them illegal in your Bill?—I may say that there is a very large feeling among the public whom I represent, that vivisection experiments, it may be only sentiment, are something peculiarly distasteful. For instance, there are many persons among them, and those whom I not the least respect, who would say that deliberately to place a dog under perfectly complete anæsthesia to throw it from the top of a high tower to see what happened to it when it hit the pavement was a brutal thing and ought not to be done even under anæsthetics.

11386. Such a thing I may say would never be done for teaching purposes?—You say that. I only say that there is a feeling among a large mass of people that they do not like an animal to be treated in that manner merely for the purpose of inquiry.

11387. But in this inquiry we are endeavouring to get at the moral or other justification for people's feelings one way and another; that is rather what I was inquiring after?—I think it is a respectable feeling on the part of people who would protest against a dog being put under complete anæsthesia and thrown from the top of a tower to see how many bones were broken or in what condition its interior parts were.

11388. That would be an experiment?—Yes.

11389. That would not be conducted at demonstrations?—The students might be all invited to come and see the demonstration conducted. It is very unedifying to a spectator, in my opinion, although the animal is under complete anæsthesia.

11390. I perfectly agree with you; but might not that be safeguarded in wording your Bill?—It would be very difficult.

11391. Would not the Home Office be apprised of the nature of the experiment that was to be done for teaching purposes?—In my opinion many of the experiments detailed by Dr. Crile, even if they were under complete anæsthesia, are repulsive to every decent person who reads them.

11392. Were those done for teaching purposes?—They might be.

11393. But they were not?—They might be.

11394. That is not the point?—Certainly they might be.

11395. They might be. But even supposing they had been absolutely painless, you are taking objection to Crile's experiment because you are not satisfied that the animal was completely unconscious? — Yes, altogether. I assure you I represent, I am not speaking for myself now, a very large number of people who, if every single experiment in Crile's book were granted to be completely under anæsthesia, would still say that such experiments were brutalising—to pour boiling water, for instance, into a dog's inside to see what would happen. There are very many people who, rightly or wrongly, think it is not the way in which dogs ought to be treated by human beings. They are the friends of man, and it is not the way to treat them; and for anybody to witness such a thing must be a brutalising spectacle and cannot be edifying. That is my answer to you about edification. And you yourself agree with me, because you say that you agree about the tower. You say it is a repulsive thing to do.

11396. For instruction purposes. My attention has been called to the fact that Sir Thornley Stoker did express the opinion (in answer to Question 761) that certain demonstrations would be of a demoralising character to young men and women who witnessed their performance, and that they seemed to him to be an offence against humanity. So that to that extent you are supported?—I thought he said some such thing.

11396A. Some doubt has been expressed as to whether the infliction of pain on animals for what might be called trade purposes comes within the purview of the existing Act. Do you think it desirable that it should?—That is really a question for lawyers. You mean whether it should be in my Bill. It would not be desirable in my opinion.

11397. Yes, I understand that your intention was to leave such cases outside the Bill; but I wondered why you discriminate between operations that are identical in every respect except the motive?—I have taken the present Act of Parliament and endeavoured to amend it. I have not drafted a new Bill altogether to deal with cruelty to animals. I find the Act as it is, and I have not changed it in that respect.

11398. Will you forgive me for saying that though in a sense it is an amendment, in another sense it is an absolutely new Bill; because you admit that the present Act legalises pain?—Yes.

11399. You want to make pain illegal?—Yes, I do.

11400. And in leaving out painful experiments incidental to trade purposes you are discriminating?—No, they are not experiments.

11401. That is only begging the question. I submit that you call the thing when it is done for the extension of knowledge an experiment, and when it is done for trade purposes not an experiment; and if you like to put the question in that way, why do you discriminate between experiments which after all are identical experiments in every respect except motive?—The difference, I think, is fundamental. I am dealing in this Bill wholly with vivisection as practised in laboratories for the purpose of either learning, or instruction, or whatever it may be. These trade products, as they

The Hon. S. Coleridge.

3 July 1907.

call them, whether they be cruel or not, differ in no way from any other ordinary cruelty to animals in the streets by mankind, and ought to be dealt with in that manner. They have ceased to be anything but trade products. If in the production of any material there is cruelty involved, that is a matter for the Royal Society for the Prevention of Cruelty to Animals; it has gone out of the purview of experiments. I am dealing solely with vivisection here. I am not going on a crusade against all experiments now; it is not my opportunity, and I did not come for that. I am not even on the committee of the Royal Society for the Prevention of Cruelty to Animals.

11402. So that it is a mere matter of convenience?—Not at all. If I was on the committee of the Royal Society for the Prevention of Cruelty to Animals, I should try and galvanise them into greater activity against many cruelties.

11403. You mean that you would try to prevent painful operations for such a purpose as the manufacture of serum?—I should if I could possibly do so.

11404. Can you assist us with a definition of what is an experiment. I noticed that you were inclined to classify the operations connected with the standardising of sera as outside the Act?—That is a question for the lawyers. It is outside the Act I presume.

11405. Why?—I do not know, I am not here as a lawyer.

11406. Do you think they ought to be outside the Act?—I do not know whether they are or not. I am not here to give a legal opinion.

11407. You have already given one?—I believe that some of the standardising experiments have been placed inside the Act. Sir Mackenzie Chalmers can tell you that.

11408. You are aware, I suppose, that a good many materials, such as milk, are tested by animal experiment as to the presence of bacteria and so on?—I was not aware of it; I will take your word.

11409. Have you never heard that medical authorities have been endeavouring to control that?—Yes, I have heard of it.

11410. Do you think that that is covered by the Act, that it comes within the Act?—If it is not painful I have no objection to it.

11411. But supposing it is as painful as other things which you say would be done for trade production and are outside the Act, what is your opinion?—If it is a painful experiment I object to it; of course, I am not here to give an expert legal opinion whether certain things come within the present Act or not—certainly in the presence of Sir Mackenzie Chalmers I would not venture to do so.

11412. I thought it was permissible to ascertain your intentions. It would fall to others, of course, to interpret your Bill if it became an Act?—Yes.

11413. Then in Clause 4 of your Bill, page 3, Subsection (1), you say that no licence is to be granted to perform more than one experiment, or one series of not more than six consecutive experiments; and in the next paragraph, that the licence is to specify the time and place at which the experiment or series of experiments is or are to be performed. Can you tell me what is the object of that? It is not, is it, to make experimentation difficult?—Oh, no.

11414. What is the object?—The idea I had in framing that was to prevent a man getting leave to experiment from the beginning of the year to the end on as many animals as he likes, without any reference to the Home Office again.

11415. Surely you might find the happy mean somewhere between a licence for each experiment and a licence extending over a year. I put it to you that there are medical officers of health, and, I believe, veterinary officers also, who daily have to deal with infective matters, or matters suspected of being infective and dangerous, and in their case it would be quite impossible to carry out experiments under an Act framed like your Bill?—What you are describing sounds to me as if it was outside the Act altogether.

11416. No, you have just admitted a minute ago that the testing of milk, for instance, ought to be considered as inside the Act?—I do not give an opinion of that kind. I said nothing of the sort. I should not say so before Sir Mackenzie Chalmers. I will not give an opinion upon it at all.

11417. But nobody has ever suggested the contrary. It is within the Act?—I do not accept your statement that it is within the Act. I do not know what the case is. I want a specific case before I admit anything tangible.

11418. I will give you a simple case. Veterinary inspectors in the employ of the London County Council have to make periodical visits to cows within the metropolitan area, and when they come across a cow whose udder appears to them to present indications of its being tuberculous, but they are not absolutely sure, then they take a sample of the milk, which is taken to a bacteriological laboratory, and there and then injected into guinea pigs; and that is done pretty frequently. There are many similar operations where the thing is coming in daily, and has to be dealt with at the time it arrives. I suggest that the provisions of your Bill would make that sort of work practically impossible. Was that your intention?—I am not quite clear that it is legal, as it is under Section 3, Subsection (1) of the Act. "The experiment must be performed with a view to the advancement by new discovery of physiological knowledge or of knowledge which will be useful for saving or prolonging life or alleviating suffering."

11419. (*Sir Mackenzie Chalmers.*) Sub-section (4) is the material one. All these, I think, come under Subsection (4)?—Yes, but you never issue that certificate; you have not for years. That is just my complaint. I quite agree with you, that if these experiments are to be performed they ought to be under Certificate D, which has not been issued for years.

11420. (*Sir John McFadyean.*) After all, you are expressing legal opinion?—I am on that point most distinctly. I have quite a clear opinion upon it. I accept Sir Mackenzie Chalmers' view.

11421. It was that that I had in my mind when I asked you to define an experiment. I put it to you that when a sample of milk, taken in the circumstances I have mentioned, comes before a bacteriologist, he wants to extend his knowledge with regard to it, and the only means of extending his knowledge is his experiment which he performs upon the guinea pig?—You are putting that upon me. I do not admit it.

11422. Will you admit that his object is to extend his knowledge?—Yes, but not that that is the only way to extend his knowledge.

11423. That is not the material point, if you will forgive me for saying so. It is the extension of knowledge by new discovery?—Yes.

11424. Surely he must extend his knowledge by a new discovery with regard to this particular sample of milk?—Well, I will accept that.

11425. Lastly, in answer to Question 10,952, you said that all these experimenters have the greatest contempt for the Act of Parliament. You may read the rest of it if you like?—No, I do not in the least wish to do so. Yes, I see that is my one little slip, I remember.

11426. Will you forgive me for saying that it seemed to me a very hasty generalisation? Would you desire to qualify it?—Perhaps the whole answer was a slip; part of it was, I remember.

11427. I did not want to go into that?—It is rather sweeping, I admit.

11428. It is too sweeping?—It is too sweeping, I admit.

11429. Will you go so far as to say that not more than a small minority have a contempt for the Act?—No, I think a good many have a contempt for the Act. They have called it "an Act of which we are all ashamed," as I have quoted once already.

11430. You ask the Commission to believe that the majority of licensees hold the Act in contempt?—I think they do.

11431. Have you any evidence of that?—I read out one letter, at any rate, in which it was alluded to in public as "an Act of which we are all ashamed."

11432. You do not possess any evidence probably in that direction that you have withheld from the Commission?—No, except that I have heard it in various ways myself.

11433. (*Chairman.*) You said just now that you knew all that you know, and all that you can know, from what is published, and that you cannot see these things

yourself?—Yes, that is with regard to bringing prosecutions.

11434. But these experiments are attended by a great number of students, are they not?—Not the research experiments.

11435. But the other ones are?—Most of those under Certificate C, yes.

11436. (*Sir Mackenzie Chalmers.*) Under licence?—Yes, demonstrations under Certificate C.

11437. (*Chairman.*) And the research operations are witnessed by skilled men, I suppose?—You mean brother vivisectors?

11438. Yes?—Yes.

11439. Does it occur to you that if anything took place at demonstrations which was cruel and negligent, I do not say that you would hear of every case, but amongst the students there would be some who would resent it?—No doubt.

11440. And who would make complaint?—No, I think very likely not. I should think that the general feeling in the profession would be much too strong for them. I do not think that a student would risk his future by making complaints against the demonstrator.

11441. You have heard no complaints, at all events?—Yes, I have, and indeed you have had them before you.

11442. From students?—Yes; you have had Miss Lind-af-Hageby.

11443. But she was a student simply for the purpose of fitting herself to inquire—to follow this matter up, as she told us. I was speaking of ordinary students who are being educated for the profession?—I should like on this to show you the kind of evidence that is constantly brought before me. I have had letters from students myself—of course, I do not give their names away.

11444. Have you made complaints upon them to the Home Office?—No, I have never done anything at all with them naturally; I cannot do anything. I should very much like to say on this question, that in this very last week I have received a letter signed by five or six undergraduates in an Oxford College, directly opposite the laboratory at Oxford, in which they complain of hearing the most dreadful howls of agony from dogs in that laboratory. Here it is, I now bring it forward to show you the kind of evidence that is brought before me constantly.

11445. These were not persons present in the laboratory?—No; but they lived opposite, and heard screams of what they say are the vivisected animals.

11446. If dogs are kept there, they may have been the screams of animals under operation; but really on this subject we have so many people who bring very strong feelings to bear that I should like something more if I am to be satisfied that these were under operations?—I am only showing the sort of evidence that comes before me. I did the obvious thing that a gentleman ought to do. I wrote at once to the head of the laboratory, told him the information that I had received, and asked for his explanation; and he gives the lie to the six gentlemen at once. All I can say is that in a Court of Justice the six witnesses would go against the one.

11447. (*Sir John McFadyean.*) They could only prove that the dogs howled?—Yes, that they heard the howls. But the answer is that there are no dogs there at all; there are only puppies.

11448. And you can always tell the difference between a howl of pain and any other howl?—Yes, that is what these young men say—that they know dogs well enough.

11449. (*Mr. Tomkinson.*) May I ask, would it be a very awkward thing for a student to give evidence against the demonstrator?—These young people are not medical students. They do not mind their names being given at all.

11450. I am speaking of students who have witnessed demonstrations, and have complained to you about them; would they not be marked men if they came forward?—Very much so.

11451. Might it not interfere with their profession hereafter?—I have not the slightest doubt of it.

11452. They would be looked upon as disloyal to their profession?—Certainly. If the Commission like to have this letter, it is very interesting.

11453. (*Chairman.*) It does not touch upon our inquiry, apparently?—It touches upon it in this way: the extreme difficulty from our point of view of instituting any proceedings or taking any possible means of protecting animals.

(*After some deliberation.*)

11454. (*Chairman.*) A member of the Commission would like to hear the letter?—"Keble College, Oxford, June 12th, 1907.—To the Honble. Stephen Coleridge,—Sir,—I (an undergraduate member of Keble College, Oxford), knowing how keenly you feel about the practice of vivisection, wish to draw you attention to the following facts with reference to this practice. My rooms are exactly opposite the University Museum. Every day, almost without exception, I hear the piercing yells of a dog in agony. There can be no doubt that it is a dog in agony and not simply one in confinement. I have ascertained as a fact that vivisection is carried on in the museum from an official to whom I spoke on the subject when I went over on Sunday last in the morning (June 9th) after hearing these same yells. Being a keeper of dogs myself, I am in a position to know the difference between a dog in agony and one in confinement, and that it is not the latter I am perfectly confident. It is always the same, and I am convinced that it is something more than merely the beating of some dog, because that would not happen every day, whereas students' scientific classes constantly take place. I wish something could be done to put a stop to these devilish practices condoned in the name of science. To one who is a lover of animals it is perfectly excruciating to have to listen to a dumb animal being put to the torture, as I hear it every day, by these scientists who, being apparently devoid of all feelings of humanity, don't care what pain they inflict to gain their object. I should be so glad if you can suggest anything to be done. I should have thought at least they were bound to do these things in places where every sound could not be heard outside. Putting aside the fact of the inhuman cruelty which this practice necessitates, it is, to speak mildly, a public nuisance. Please use my name or letters as much as you wish.—I am, Sir, yours faithfully, HAROLD S. SHARPE." And then: "We, the undersigned, desire to state that we have also heard these yells, and wish to corroborate all Mr. Sharpe has said.—ARTHUR H. M. PEAT, CYRIL A. BONSER, ALFRED C. C. HARNEY EVANS, GEOFFREY HEALD, BASIL W. TRUMAN." I at once addressed a letter "To the licensees for the performance of experiments upon living animals, The University Museum, Oxford," dated the 14th June: "Gentlemen,—I have received from a correspondent, whose credibility I have no reason to doubt, an account of cries of dogs or of a dog in agony that emanate from the buildings of the Museum at Oxford. A portion of the buildings in question being a place registered (under the Act 39 and 40 Vic., c. 77), for the performance of experiments upon living animals, and you, gentlemen, being under the same Act licensed to perform such experiments in that portion of the buildings, I beg leave to inquire whether these cries come from your laboratories, and, if so, whether you feel disposed to offer any explanation of these most distressing sounds.—Yours obedient servant, STEPHEN COLERIDGE." Then I got this letter from Mr. Francis Gotch: "Physiological Laboratory, Oxford, June 16th, 1907.—Sir,—In answer to your letter of the 14th inst., I beg to state that no vivisection experiments on dogs have been carried out in this laboratory during the present year. Four puppies were born and kept in the adjoining yard, and the shrill yelps of these animals when at play were presumably the sounds heard by your correspondent. This might have been ascertained by making appropriate inquiry.—Yours faithfully, FRANCIS GOTCH." I sent this letter with my compliments to these young gentlemen, and this is the answer that they sent back to me: "Dear Sir,—I am sorry I have been away and only just returned and found your letter. Professor Gotch is a liar." These young gentlemen write like young men. "A man in Keble who is in for anatomy told Mr. Heald (one of those who signed my paper) that they did cut up rabbits, and that lately they had cut up a small dog, and this had been yelling for a week. It is perfectly absurd to say that the yells I hear are anything else than dogs, or possibly some other animals in agony.

The Hon. S. Coleridge.

3 July 1907.

The idea of puppies is ridiculous. I have heard the puppies yelp very frequently, and I have also heard a dog scream, and I would swear to it anywhere. Mrs. Herford, writing to me to-day, says: 'It is distressing to pass the Museum for the yells one frequently hears.' Would two people be such fools as to mistake a painful yell for a puppy's yelp? It shows that Mr. Gotch is a liar, because one dog has been cut up this term. The man who told my friend (Heald) this said they did cut up rabbits. That is sufficient. Mr. Gotch says I might have ascertained the truth by making appropriate inquiries. I asked an official, as you know, and he said vivisection was practised. I would maintain, in spite of Mr. Gotch's statements, that animals have been cut up this term. If a man is devil enough to be a vivisector he can easily reconcile his conscience to a lie or two, especially when Mr. Coleridge writes to him, for he knows matters might be made hot for him." (This is very youthful.) "I am unable to get more facts than these: (1) One dog for certain has been vivisected this term; (2) also rabbits; (3) the cries I hear are *not* puppies'—Yours sincerely, HAROLD S. SHARPE." That is the sort of thing that is constantly coming before me, and that is the result that I get.

11455. It seems to me that the letter is about as reasonable as if Mr. Gotch were to answer it by saying: "No such thing has happened as you say, and as to your saying you heard it, all antivivisectors are liars, and I do not believe them." It does not carry it much further?—I do not think that is quite it, my Lord. We cannot carry it further. Here are six young gentlemen who write to me with no motive whatever but the motive of humanity. I admit that the language is the language of boys.

11456. (*Dr. Gaskell.*). What is the date that Mr. Gotch gave when he asserted that no animals had been experimented upon?—"No vivisection experiments on dogs have been carried out in this laboratory during the present year." The date is June 16th, 1907.

11457. "This term" meant distinctly during the time that Mr. Gotch was there and must have known?—It must have meant that. They give Mr. Gotch the lie.

11458. (*Chairman.*) It is possible that Mr. Gotch may be a witness here?—The difficulty is that under the present Act there is no Inspector, and nobody knows what happens. You get these opinions outside and inside, and who can judge?

11459. (*Sir John McFadyean.*) After all, the only direct evidence produced in that correspondence is that the cries that they heard are interpreted as cries of pain?—Yes; but these young fellows say that they know the difference between cries, and that they were the cries, at any rate, of dogs.

11460. (*Dr. Gaskell.*) Was there any definite date given when that small dog was cut up?—"Because one dog has been cut up this term"—it is "this term."

11461. (*Sir John McFadyean.*) That is not direct evidence?—No.

11462. (*Mr. Tomkinson.*) Does he not say that he called at the door, and an official admitted it?—"I asked an official, as you know, and he said vivisection was practised." That is his statement.

11463. (*Dr. Gaskell.*) He does not even say whether that dog that was cut up was alive or dead?—He does not. The context rather indicates that it was alive.

11464. You do get them for dissection dead?—Yes; but the suggestion in the context here is that the dog was alive.

11465. That is the suggestion, certainly?—Yes.

11466. (*Sir Mackenzie Chalmers.*) Did you send that second letter to Mr. Gotch, and did you get a further reply?—No, I left the matter there.

11467. There is a contradiction of fact?—Yes, a flat contradiction. It was no use carrying it any further.

11468. (*Dr. Gaskell.*) I do not quite understand your position with regard to Certificate B. I should like to have a little more explanation about it. I understand that you are desirous to abolish it in your Bill altogether, because you look upon it as entailing a greater amount of torture than anything else?—I think that more pain is inflicted under the present law under that certificate.

11469. Certificate B, of course, you know is for the purpose either of cutting out some organ or cutting some nerves and keeping the animal alive afterwards; that is the kind of operation?—Yes, doing some serious operation and allowing the animal to recover; that may be one of the objects.

11470. That is the object?—No, not the object; it is one of the objects of Certificate B.

11471. I understood you to assert, in answer to Question 10319, that Certificate B dispenses with anæsthetics immediately after the initial operation is over?—Yes, the new wording does do that ever since 1899.

11472. That is your main point about the torture?—Yes.

11473. Do I rightly understand that it is the initial operation that you think torture may be inflicted in especially?—No, you have mistaken me. My point is that under Certificate B, as now worded, anæsthesia must be applied during the initial operation of opening the animal and fixing the electrodes to different nerves, or whatever it may be. Then I say that under Certificate B the animal can be kept in that condition on the board, and allowed to recover its consciousness, and the animal can be kept there disembowelled, or whatever it may be, as long as the operator chooses, without any anæsthesia to allay its sufferings.

11474. That is your interpretation of the word "initial"?—That is what the certificate means.

11475. Pardon me; I think not. That is your interpretation of the initial operation?—Yes.

11476. If such certificate were worded differently, you would have no objection to it. Supposing, instead of being worded as it is here, "Being during the whole of the initial operation of such experiment under the influence of some anæsthetic," and so on, it was worded, "During the whole of the operative procedures in connection with such experiment," would that meet your difficulty?—No; because my objection is that, after the operative procedures are over, during the period merely of observation of the animal, it may be lying in dreadful pain without anæsthesia.

11477. That is still part of the operative procedure?—No; looking at a board and watching the blood pressure is not an operative procedure.

11478. Stimulating the nerves is operative?—No, you need not touch the dog. To operate is to touch, certainly.

11479. Then we will have any form you like. There is no question whatever that that initial operation is included under Certificate B, and is intended to include the whole procedure while the animal is under anæsthesia?—You say that.

11480. That is so?—I will not admit it for a moment. Why were the words "During the initial operation of such experiment" put in? It used to run "During the whole of the experiment."

11481. The whole point of Certificate B is that the animal should have recovered from the initial operation; is not that so?—The initial operation, yes, of such experiment.

11482. And the initial operation means the cutting of the nerves or the removal of the organ, or what not?—Yes.

11483. And then after that till the animal is sewn up—the whole thing?—Not necessarily at all. It may be for hours on the board in that condition before it is sewn up.

11484. How can it be so?—There are such experiments.

11485. Would you mind showing me a single experiment of that sort under Certificate B?—I say that such can be done.

11486. Will you show me one that has been done under Certificate B? I have never seen or heard of such a case?—I say that the words of the certificate admit of it.

11487. Are you aware that in order to make the thing quite clear, in every Certificate B of late years (I know it in the case of Mr. Ritchie in 1902, and I know it in the case of Mr. Akers Douglas in 1904) there is always this inserted: "All operative procedures in connection with any experiments, except experiments under Certificate B, plus EE, to be carried out under an anæsthetic of sufficient power to prevent

the animal from feeling pain"?—I quite admit that during the operative procedure—that is, using the knife.

11488. No?—I think it is obvious.

11489. Surely everything up to the stitching up is an operative procedure?—No, my contention is—I may be right or wrong ——

11490. I think you are absolutely wrong?—That is on the knees of the gods.

11491. No, it is a fact?—Here are the words of the certificate—this is the old certificate I am going to read you: "Such animals being during the whole of such experiment under the influence of some anæsthesia of sufficient power to prevent their feeling pain"; then the animal is allowed to recover under that.

11492. During the whole of what?—During the whole of such experiment; that was the wording of the certificate before October, 1899.

11493. Does that not confuse the term "experiment"? The experiment is not simply the operative experiment to begin with; it is the whole thing?—My point is that in 1899 the words were put in, "During the whole of the initial operation of such experiment." My contention—I may be right or wrong—is that the whole experiment may consist of first opening the animal and fixing electrodes to its cut nerves, or putting tubes down its arteries, and then it may be left on the board in that condition, fixed tight, so that it cannot move, and in that condition it may be allowed under this certificate to recover consciousness, and lie there bound at the will of the operator. I say that is part of the experiment, and it is not an operative procedure.

11494. But it is not Certificate B at all?—Yes, it is.

11494A. Certificate B is always for the purpose of keeping the animal alive afterwards; and for that purpose you would certainly not begin by putting tubes in a cut up animal in that sort of way?—I asked the very question of the Home Office, and I got a reply which confirmed my view of it.

11495. I should like to hear that reply?—I read it last time. Here it is. I asked, "Whether conditions are invariably added to this certificate" (that is Certificate B), "enforcing the employment of anæsthetics ensuring insensibility to pain from the commencement of the first operation until the conclusion of all manipulations of the animal, and until the last wound is closed aseptically." That is a very plain question, which obviously is directed to the very point on which you and I are at issue.

11496. Quite so. What is the answer?—The answer is: "Whenever the experiments would involve a series of cutting operations (which is very infrequent), conditions are added to the licence enforcing the employment of anæsthetics ensuring insensibility to pain during all operative proceedings." I maintain that that question and answer leave my contention untouched; that the animal may be opened and operated upon, and then left upon the board as long as no fresh cutting operation is performed (they absolutely say "cutting" here) without anæsthetics, under the conditions of that certificate.

11497. I should have thought that any commonsense person would understand that "all operative procedures" meant the operations right up to the time that the last stitch was put in?—That is the question that I asked.

11498. That answer implies it?—The question is: "From the commencement of the first operation until the conclusion of all manipulations of the animal and until the last wound is closed aseptically." I asked whether the anæsthesia really covered the whole of that period—the initial operation, the period of observation, and the final sewing up—and I did not get a reply which supports your view.

11499. Have you ever asked anyone who has operated under Certificate B?—I asked the Home Office the plain question what the certificate means. I give them the opportunity of giving me an answer, and they give me an answer which satisfies me that your contention is wrong.

11500. But that answer is distinctly in accordance with my contention?—I think not.

11501. Most emphatically?—I do not agree with you; "during all operative procedures"—that is all.

11502. The operative procedure I should have thought, certainly, so far as my knowledge goes, as recognised by all persons in laboratories, does include the whole of that initial thing?—The animal may be opened, as I have said, and be prepared. What is there in the wording of this answer to prevent that animal being allowed to recover, and lie on the board for hours before they begin to sew it up?

The Hon. S. Coleridge.

3 July 1907

11503. The words "operative procedure"?—There is no operative procedure. The animal is lying there, and nothing is done to it; it is not being touched; it is only being looked at. To look at an animal is not an operative procedure. I say the animal might be only looked at for an hour of two, or three hours, in that condition without any anæsthesia, under that certificate.

11504. You cannot give me an instance, I presume?—I am not a vivisector; I do not go into laboratories. I am only on the law.

11505. Have you examined the various Certificates B, which have been issued, to see the nature of the experiments?—They are not sent round to my office to be examined.

11506. Can you not get them?—No, I cannot. I have asked for them, and have met with a flat refusal. I have been given a courteous reply, but they will not submit them to me.

11507. You know that it is stated on the certificate that the man must describe the nature of the operation and his object in performing the experiment?—I daresay.

11508. Then it goes on to say, "All operations in connection with the experiment to be carried out under anæsthesia of sufficient power to prevent the animal feeling pain." My contention is undoubtedly that that does include the whole thing. You say that in your opinion it might be used, but you can give me no evidence that it has ever been used in the way you indicate?—I did not come here to give evidence of what I have seen in laboratories. I have never been in one.

11509. You suggest that?—I say so.

11510. To my mind it is a most extraordinary suggestion. I never heard of such a suggestion before?—I daresay not.

11511. It is impossible for me to conceive how it can come into your head?—Here is the law.

11512. No, the operative procedure takes in the whole of it. Then, apart from that, I presume that that is your main objection to Certificate B?—That is a very considerable one.

11513. Then that part of the objection would go if it was shown to your satisfaction that such an occurrence as you indicate has never taken place?—You could not possibly inform me that such an occurrence has not taken place. You are not in the laboratories any more than I am. It may be your opinion that such things do not take place, and it may be my opinion that they do; neither of us has a right to say that it has or has not occurred.

11514. Do you not understand that the very kind of experiment that you are putting down is an experiment that would be conducted under licence alone?—No, I do not say that for a moment.

11515. You do not understand it?—Yes, I do perfectly. I understand it too well.

11516. Then, I presume that you also consider that under Certificate B there is pain or considerable liability to pain afterwards?—What do you mean by afterwards?

11517. I mean to say after the whole thing?—What is your interpretation of "the whole thing"?

11518. After the operative procedure is finished with, and after the animal is kept in the laboratory?—When it is sewn up?

11519. Yes?—My answer to that is that I should think there may or may not be pain. In some cases there might not be pain, and in some cases there might be. I suffered considerably after I had an operation upon myself, I know.

11520. Are you aware that it is the custom now to add to that Certificate B these words: "The animals experimented upon under Certificate B, plus EE, must be treated with strict antiseptic precautions, and if these fail, and pain results, the animal must be killed under anæsthetics?"—I hear you say so.

11521. That is usually put on the certificate?—I accept your statement. I do not see these certificates.

The Hon. S. Coleridge.

3 July 1907.

Sir Mackenzie Chalmers ought to answer that question, not I.

11522. Is it not the fact that in consequence of asepsis, as used in hospitals, a very large number at all events of the operations are followed by painless results?—The suggestion was made, I think, by Mr. Starling that the surgical wards of hospitals are a kind of merry place for everybody, laughing and joking. I have asked several people, and I have not had that extreme view of the happiness of surgical wards confirmed. I do not deny what you say. I daresay that under asepsis very many operations may heal without very much pain. I imagine that others will be painful.

11523. In answer to Question 10,839, you said that by pain you meant real severe suffering?—Yes.

11524. Not small discomfort?—No, serious pain was the term I used, which I have agreed to add to the clause in my Bill.

11525. And you also said, in answer to Question 10,834, that you were willing to accept the Inspector's verdict as to whether an animal is in pain or not?—Yes.

11526. Of course, you know that one of the main duties of the Inspector when he comes to a laboratory is to examine all the animals which have been subjected to an operation under Certificate B?—I do not know what the instructions given to him are. The only definite instruction that I recollect having been given here in evidence is that he is not to consider himself a detective. I do not know of any other definite instruction which has been given to him, so far as I can gather from the evidence.

11527 We have had it from the Inspectors themselves that they invariably examine these animals?—If they say so, I have no reason to doubt it.

11528. Consequently they do see all the cases of animals which have been operated upon under Certificate B?—No, I am not prepared to admit that, for very good reasons. I have brought information before the Home Office that an Inspector had been to a registered place, and had not seen a very considerable number of horses which were in great suffering in another part of the building; and he was not taken to see them. I have that evidence with me, for what it is worth. I submitted it to the Home Office at an interview. Therefore I am not prepared to admit that the Inspector always sees every animal in the building.

11529. The Inspectors told us that they do go, at all events to all the places in the building where they can find animals?—They might have found these horses, but they did not. They go where they are taken by the vivisectors.

11530. At any rate we have had evidence from Professor Thane and Sir James Russell, that again and again—in fact, in all cases when they have examined these animals, they have found that they were not suffering pain?—But that evidence of mine is before the Commission.

11531. So that I do not see why you are willing to retain Certificate A, and are determined by your Bill to abolish Certificate B. Is there not much less suffering, from the evidence of these Inspectors, under Certificate B, than there is under Certificate A?—If that is the evidence of the Inspectors, I am not prepared to combat it; but what I have pointed out, and what I think I have made perfectly clear, is, that my objection to Certificate B mainly is as to the conditions that are inflicted upon animals when there is no Inspector there.

11532. After the initial operation?—Yes, that is my point; that is my chief objection to Certificate B.

11533. We may have more evidence upon the question, no doubt, but so far at present as the evidence goes I have no reason to suppose that such an operation as you suggest has ever been made under Certificate B. I wish you could produce some evidence that it has been, because it is new to me entirely?—You must remember, when you put up the evidence of the Inspectors against anything that I have said, that I have already asserted my opinion, and I think I have supported it by a large amount of evidence, that the Inspectors are not unbiassed.

11534. Still, you have asserted definitely here that you are willing to accept the Inspectors' verdict?—The verdict of future Inspectors. I would certainly not have accepted the opinion of Dr. Poore on the question of the humanity of vivisectors.

11535. I thought you said just now that the future Inspectors were still to be appointed by the Home Secretary?—Yes, but there is that consideration about their humanity under my Bill.

11536. (*Chairman.*) No; it is the humanity of the operators that you get a certificate for, not the humanity of the Inspectors?—I think I have provided for the Inspectors too. It is in the proviso to Clause 7: "Provided always that in the appointment or assignment of such Inspectors by the Secretary of State, special regard shall be paid to the applicant's reputation for humanity."

11537. That is not a certificate, but "special regard"?—Yes.

11538. (*Dr. Gaskell.*) Would you consider that Certificate B might be retained if it applied only to animals which were operated upon under strict aseptic conditions. Do you consider that aseptic conditions before operation make a great difference with respect to the after question of pain to the animal?—That is a matter for experts. If the experts say so I am ready to accept, certainly, that asepsis does make a difference.

11539. What I am thinking of is this: I can understand your objection to experiments like those of Dr. Cecil Shaw, where septic material was put into the eye—that is, undoubtedly, I should think, a painful experiment; but in the case of a large majority of these experiments under Certificate B the Home Office directly insist on their being done aseptically for the purpose of preventing pain. Would you not allow Certificate B to exist if you were sure that that was always done?—My objection to Certificate B is that in its present form it permits something very much worse than that. You see what I am after.

11540. May I ask you, will you describe Certificate B in such terms as to avoid that initial operative difficulty of yours?—It is not in my province to be a draftsman, I have not done it, but I think it might be drafted in such a way as to preclude that possibility. I think it might be done with a little care.

11541. And if it was so drafted, would your contention still be that Certificate B ought to be abolished? If it was drafted so that the operative procedure, as I understand it, was really put in plain English so that you could understand it, would you still object to Certificate B?—That is the same question that Mr. Ram put to me, I think.

11542. I want to make it quite clear, because I want to understand why you make such a dead set against Certificate B when, so far as I can judge from what we have been told in evidence already, there is very little pain involved under it.

(*Sir John McFadyean.*) Mr. Coleridge has already said that he would put the animals under the same conditions as they are under Certificate A, because then he would be assured that they were anæsthetised throughout the whole of the operative procedure.

11543. (*Dr. Gaskell.*) What I put to you is this: What the vivisectors generally consider, you would say that you do not accept it, is that Certificate B implies exactly the same thing as occurs in every operation in a hospital?—I cannot agree to that.

11544. It is just like a surgical operation under anæsthesia, the animal recovering just as the patient does in a hospital?—I cannot admit that.

11545. (*Chairman.*) I think we all know what Mr. Coleridge's view is upon that point. (*To the Witness.*) As I understand, it is that you say that after that animal has been allowed to come out of the anæsthesia there is an interval, sometimes long, sometimes short, in which it suffers great pain?—That is my objection to Certificate B.

11546. (*Sir Mackenzie Chalmers.*) Whether that happens or not the certificate allows it, that is your point?—Yes, that is my point.

11547. (*Chairman.*) How far Certificate B does cover that is a question that we can settle for ourselves. It is either a question of the construction of a document or it is a question of fact as to whether the animals suffer pain?—Yes.

11548. (*Dr. Gaskell.*) In speaking about slight anæsthesia you stated in answer to Question 10387,

"You cannot be slightly without feeling. You either feel pain or you do not"?—I have taken the word in its proper sense.

11549. Do you mean to say that you cannot be conscious and yet not feel pain?—"ἀναίσθητος" means "unconsciousness."

11550. But can you be conscious without feeling pain?—I never have been myself.

11551. Is it not the case often in battle?—I am not a soldier.

11552. When worked up to a state of excitement, is it not the case that people do not feel the pain of wounds when they are cut?—I believe it is a well-known fact that when you are shot you do not feel the pain at once because of the shock to the nerves all round.

11553. Is it not the case in hypnotism that you can still be conscious and not feel pain?—I have not been hypnotised. I do not know about that.

11554. Do you also know that in lunatic asylums patients burn themselves and the sun burns them, but they do not feel pain?—I really do not know what lunatics feel; I have no experience of lunacy, I am glad to say.

11555. But you have told us distinctly that slight anæsthesia means that the animal feels pain?—I do not know that they have lunatic animals in laboratories. The parallel of lunacy does not seem to me to come in.

11556. I mean to say that in all these cases it is possible for consciousness to exist and yet pain to go?—That is your assertion. If you ask me to affirm it or to agree to it, I do not.

11557. You know, of course, I presume, that the corneal reflex is only one of many reflexes?—I am not a physiologist. I decline to discuss physiology with you or anybody.

11558. But you distinctly assert that unless the corneal reflex is abolished the animal feels pain?—I took that from the correspondence before me.

11559. No; all the correspondence before you said was that if the corneal reflex is abolished the animal is under deep anæsthesia.

11560. (*Chairman.*) I think everybody agrees that the corneal reflex is one of the last to disappear?—Yes, I agree to that.

11561. (*Dr. Gaskell.*) Will you not agree then that pain may disappear before the corneal reflex is abolished?—That is another thing.

11562. Just a question about Dixon and Brodie's case of light anæsthesia. I understood you to say, in answer to Question 10375, that the animal was under torture?—I say that I regard that experiment with profound distrust. I should like to have had the Inspector there.

11563. Do you not know that at these experiments a registering apparatus was being used?—I do not know in the least. I was not there.

11564. But do you not understand that if an animal is in pain it would show signs of that pain?—Not if it had curare. I do not know whether it had in this case.

11565. It was not a question of curare?—I do not know.

11566. And if the animal was in real pain do you think that the curves could have been registered by the apparatus in the way that they were?—There is a mention of curare (on page 144 of the "Journal of Physiology," Volume XXIX.): "In no instance have we obtained any effect by exciting the central end of the sciatic in a curarised animal" (I did not see that before), "but the experiments are not numerous." So that he did use curare.

11567. Not with the slight anæsthesia?—You do not know that.

11568. That is not the point. You were talking of slight anæsthesia?—Yes, and you asked me if the animal would not show signs of pain. I say, not if it was curarised.

11569. I want to know whether you do not consider when a delicate registering apparatus is going on in the animal, which moves perfectly smoothly and gets real good curves, even although the operator says the animal is under slight anæsthesia, that does not show that the animal was not feeling pain?—Not necessarily. I have an answer to that, of Sir Victor Horsley, in the case against me on that very point that an animal can be held tight when it does not move. (*Mr. Rufus Isaacs.*) Would it be possible to perform the experiment or the demonstration which we know took place, if the dog had been conscious? (*Sir Victor Horsley.*) No, absolutely impossible unless the dog had been fixed up with all manner of apparatus, to absolutely fix every bone. You can fix an animal with apparatus of *that* sort. (*Pointing to the operating board.*) That is the answer to that—you can so fix an animal on that board—and he pointed to it—they had it in Court.

11570. (*Mr. Tomkinson.*) Would your Society, if it could obtain all that it wished, go for total abolition of vivisection?—We should willingly and delightedly accept total abolition if we thought that it was within the range of practical politics; but we do not think that it is within the range of practical politics in the present state of public feeling; therefore rather than leave animals to their present fate we wish to get what we can for them.

11571. You are aware that some other societies look coldly on that attitude?—All the other societies I believe are against my own Society for taking that view.

11572. Your main point I think is that the present inspection is extremely imperfect—that it is practically non-existent?—Yes, from the animal's point of view.

11573. And that when there are cases of supposed or stated cruelty or evasions of the Act, which are brought to the notice of your Society, or complaints are made from any other quarter, the whole of the evidence of refutation has to come from the parties who would be incriminated?—That is so; either incriminated as first principals or as aiding and abetting—witnessing without protest.

11574. And you think that permission of some of the public, at all events to pay surprise visits, would be very desirable?—Yes, certainly, if it could be obtained.

11575. The use of curare you wish to prohibit altogether?—Absolutely.

11576. And morphia you do not accept as a perfect anæsthetic by itself?—No.

11577. (*Sir Mackenzie Chalmers.*) Or urethane?—No, nothing but a respirable gas. Those things take some time, at any rate, to act. If you give a poisonous dose of morphia to an animal, it cannot be said to be anæsthetised, I presume, for a considerable time.

11578. (*Mr. Gaskell.*) Do you say that morphia does not take away pain?—I did not say so. I am ready to accept expert evidence that a poisonous dose of morphia is a complete anæsthetic near the period of death.

11579. That is on the question of consciousness. I am simply on the question of pain. Is not morphia the one drug that is used for removing pain?—I never heard of anybody having a leg cut off under morphia alone; therefore I do not accept it as a general anæsthetic. If it were so, the triumph with which the discovery of anæsthesia was hailed would not have been justified, if morphia was a complete anæsthetic; because it was discovered many years before the discovery of chloroform.

11580. I should have thought it would be admitted, according to the evidence that we have had, that large doses of morphia undoubtedly remove pain entirely?—I do not accept that.

11581. (*Mr. Tomkinson.*) A great many questions have been asked, both of you and other witnesses, with regard to other forms of cruelty to animals which we know do exist, and I think that your position is perfectly consistent as a non-sportsman. We must all agree that there are such cases of cruelty, especially in the trapping of animals, which to my mind is the most cruel of all, and also in regard even to the slaughter of animals for food. Animals which are troublesome or violent or very noisy, such as oxen or pigs, are supposed to be stunned before being killed, for instance?—No doubt there are cruelties in slaughter-houses which ought to be put down.

11582. But in the case of what are called farmyard operations, castration and the like, with regard to what Sir John MacFadyean put to you, do you know

The Hon. S. Coleridge.

3 July 1907.

of any case in which an animal is strapped to a board?—No, I do not.

11583. So far as my experience goes, that operation is only performed as an absolute necessity to enable animals to live?—That is my impression.

11584. Neither bulls nor horses could be allowed to continue entire, on account of the danger that it would be?—That is my belief.

11585. And with regard to pigs, are you aware that the operation is an instantaneous one, and apparently in small animals, such as lambs, so little painful that its after effects are not noticed at all by the animals?—So I should imagine. I have not seen them.

11586. Therefore it is not a question only of convenience, but a question of even allowing these animals to have their lives, certainly in the case of horses and bulls?—They would otherwise have to be destroyed, I suppose.

11587. Undue importance has been attached to that, in my opinion. Did you read a statement in an anti-vivisection pamphlet about the supposed baking of rabbits?—It did not issue from my Society.

11588. Have you read Sir Lauder Brunton's explanation of that before this Commission?—Yes, about its not being hotter than a Turkish bath.

11589. Was that explanation satisfactory to your society?—I have not gone into that.

11590. You know the statement was that so far from there being any cruelty or any baking or any excessive temperature, it was merely a warm bottle and cotton wool in order to prevent the temperature of the patient falling below a certain point?—I am not prepared to give an opinion upon that one way or the other. I have not studied it.

11591. (*Sir Mackenzie Chalmers.*) I think you said that your Society were not responsible for that pamphlet?—I do not think so. I do not think it is any publication of my Society.

11592. (*Mr. Tomkinson.*) Do you know anything of the offender against the law, I think you said his name was refused, who was deprived of his licence?—No, I do not know who he was to-day.

11593. But you said that he was reinstated afterwards?—Yes.

11594. Then as to starving animals, we have been told on a previous day that starvation does not entail pain. It is a rather novel idea, I think, when we remember all the stories we have heard of the experiences of people who have been starved after shipwreck and on other occasions?—Ugolino, for instance.

11595. (*Dr. Wilson.*) And starvation is awarded as a punishment?—I never thought of that. It is awarded as a punishment in prisons—or it was certainly at one time.

11596. (*Mr. Tomkinson.*) It is rather a startling statement to an ordinary person?—Yes.

11597. (*Dr. Wilson.*) Although you do not pretend to give an expert opinion, I take it for granted that your Society has from the outset amassed a large amount of literature on this subject of experimentation on living animals?—Yes.

11598. And your society also publishes a journal called "The Zoophilist"?—Yes.

11599. So that with regard to the usefulness of these experiments and their justifiableness, the editor of that journal is constantly scrutinising all the literature and reports which come to you?—Yes.

11600. May I ask whether the editor is coming to give evidence?—With a view of shortening the proceedings, I think I have represented pretty well all that my Society has to say. If the Commission desire to see him I have consulted with Dr. Berdoe, and he says he does not want to come unless you want him. I have also consulted my committee, and they say that if you would like to have him they will put him forward, but that he would more or less cover the same ground that I have done.

11601. (*Sir Mackenzie Chalmers.*) Is Dr. Hadwen connected with your Society?—No, we have nothing to do with him at all.

11602. You do not wish to answer for him?—Oh, dear, no.

11603. (*Dr. Wilson.*) You have already been asked many questions concerning the various clauses in your Bill which you have drafted and which has been approved by your Society. I suppose you will admit that the element of pain so long as these experiments are allowed can never be eliminated?—I suppose not in inoculation experiments altogether.

11604. Nor in experiments under Certificate B?—Not with Certificate B altogether, certainly.

11605. It has been admitted before this Commission that in a good many of those inoculation experiments pain, of course, cannot be avoided?—That is so.

11606. And also in a few experiments under Certificate B pain cannot be avoided?—No.

11607. The question of credibility has been so often raised, supposing you were assured, as several witnesses have assured this Commission, that no matter how prolonged and severe these experiments may be that are carried out, and no matter under what anæsthetic or narcotic they are carried out, they are absolutely without pain, would you accept that statement?—Certainly not.

11608. Would you accept it as a statement of opinion then?—Yes.

11609. But you would doubt it as a statement of fact?—Yes, I do not think I could accept it. It is not the opinion probably of the animal.

11610. Supposing that experiments are still permitted to be carried on before classes, and that all experiments were required to be carried out under anæsthesia, would it give greater satisfaction to your Society if every experimenter were required, in forwarding his reports of experiments, to fill up a form of certificate in respect to them to the effect that to the best of his endeavour and belief the experiments had been carried out painlessly?—Oh, no.

11611. That would afford you no satisfaction?—Certainly not.

11612. Still, after all, no matter what amount of inspection you may have, you must put some reliance surely upon the *bonâ fides* of the experimenter?—Of the Inspector, certainly.

11613. No, of the experimenter?—I quite admit, as I have already said, I am perfectly ready to admit, that there may be many licensed vivisectors as humane as myself. The object of the Act of Parliament is to enforce that humanity upon others who are not so humane; and that is the object of my Bill, to enforce that humanity upon those who have not got it.

11614. You think there is always a great risk of their becoming so keen in research that they may become callous towards the infliction of pain?—Yes, certainly.

11615. You have raised a strong objection to the Association for the Advancement of Medicine by Research having been selected by the Home Office as their advisers?—Yes.

11616. Whether that society has turned out to be biassed in favour of vivisection or not, can you not conceive that the Home Office or the Secretary of State at the time was influenced entirely by a desire to have the Act carried out more strictly and with the greatest possible care?—The evidence of Mr. Byrne, I think it was, is that the Home Office had no knowledge of the constitution of this society. It did not know who its president was, and, so far as I could make out, he knew very little about it.

11617. But when it was originally started I think it embraced many eminent men, such as Lord Lister and the late Sir William Jenner, whose names have been mentioned in connection with it. However, that is immaterial. Would you be satisfied if instead of that society, a statutory body such as the General Medical Council were made responsible?—I have already answered that question, by saying that I should not object to a body which had no licensed vivisectors upon it. I think that they should not report upon themselves.

11618. The General Medical Council consists, of course, of some of the most eminent men and teachers in the profession, and that body is entrusted with the registration of all qualified medical men, with the standard of education of medical students, and also with the power of removing from the register any medical man who misconducts himself in any way.

Would you be satisfied with a body such as that?—If there were no licensed vivisectors upon it, yes.

11619. That body is responsible for the education of the medical profession, so that the onus then would be thrown upon the profession instead of upon the Home Office for granting licences?—My desire is to separate licensed vivisectors from the medical profession. I do not include them in any way in my mind with the medical profession. In my mind the medical profession, as a rule, are not vivisectors.

11620. But, after all, is not the consensus of leading medical opinion of the day in favour of experimentation on animals?—I expect it is—the expressed opinion. What the unexpressed opinion may be, I do not know.

11621. Then it is a question between the public really and the profession, is it not?—No, I do not say that for a moment. I said the expressed opinion of the profession. There are numbers of medical men who agree with me who do not like to say so out of *esprit de corps.*

11622. I need not press that point?—But my Bill does not abolish vivisection.

11623. No, you only wish to protect animals as much as possible?—Yes.

11624. (*Chairman.*) Is there anything further you wish to say?—There is one point I should like to mention. I want to read a letter from the Duke of Portland, who is chairman of the Dogs' Home at Battersea, with regard to a suggestion which was put to Mr. Starling by, I think, Sir Mackenzie Chalmers, about using the Dogs' Home as a sort of source of supply of dogs for vivisection.

11625. (*Sir Mackenzie Chalmers.*) It was suggested by one of the witnesses?—Yes, I think it was Professor Starling. You asked the question, and he thought it would be a good thing. I accordingly wrote to the Duke of Portland as Chairman of the Home, to know whether he would approve of such a use being made of his Dogs' Home.

11626. He objects on behalf of the Home, of course?—Yes, he says: "Dear Mr. Stephen Coleridge,—Many thanks for your letter. I think Mr. Starling's suggestion is not only horrible but absurd, and it is one which, both as President of the Lost Dogs' Home and as a private individual, I should feel bound to resist as strongly as I possibly could. I say the suggestion is absurd because I am convinced it would never be accepted by the majority of the subscribers to the Home, and I have no doubt if persisted in it would mean the closing of the Institution and the loss to the public of much useful work at present undertaken and carried out by voluntary subscription. I am sending your letter and my reply to the Secretary of the Lost Dogs' Home, and, personally, I shall be glad to know that you have opposed Mr. Starling's suggestion, and I am, yours sincerely, (Signed) PORTLAND."

The Hon. S. Coleridge.

3 July 1907.

11627. (*Chairman.*) Is that all you wish to say?—Before I go, my Lord, I should like to say this one word in parting. I have to thank the Commissioners very cordially for their kindness in listening to me so long, and I wish just to say this one thing. As regards the courtesy with which Sir Mackenzie Chalmers has treated me, I shall always feel very grateful, and personally nothing but pleasure, in having been able to bring accusations against the Home Office face to face with the Chief of the Department. But having said that, I wish to emphasise, if I may, that I cannot help feeling rather forcibly that after I have left this room Sir Mackenzie Chalmers remains in the position of judge upon the indictment which I have felt it my duty to bring forward; and I therefore feel that the situation is a peculiar one—it is not one of my making at all; but I do think it ought to be remembered as a fact that after I have withdrawn Sir Mackenzie Chalmers remains as the judge upon the very points which I have brought as an accusation against the Home Office of which he is the head.

11628. Whom he has to advise?—Well, to advise. But I feel sure that in the circumstances, having had the great pleasure of being cross-examined by Sir Mackenzie, he will meet that difficulty in a spirit to which nobody could have, and certainly I have, no objection.

11629. I think I should say that yours is not an extraordinary position. Upon every Commission relating to an Act of Parliament there is some member representing the administering department. It is quite usual. It is only that this happens to be a case in which feelings are moved more than they are, perhaps, in regard to motor-cars or London traffic?—It puts me somewhat at a disadvantage.

TWENTY-SIXTH DAY.

Wednesday, 10th July 1907.

PRESENT:

The Right Hon. The Viscount SELBY (*Chairman*).

Colonel The Right Hon. A. M. LOCKWOOD, C.V.O., M.P.
Sir W. S. CHURCH, Bart., K.C.B., M.D.
Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir J. MACFADYEAN, M.B.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. A. J. RAM, K.C.
Mr. W. H. GASKELL, M.D., F.R.S.
Mr. J. TOMKINSON, M.P.
Mr. G. WILSON, LL.D., M.D.

Captain C. BIGHAM, C.M.G. (*Secretary*).

Mr. C. J. MARTIN, M.B., D.SC., F.R.S., called in; and Examined.

Mr. C. J. Martin, M.B., D.Sc., F.R.S.
10 July 1907.

11630. (*Chairman.*) You are, I believe, Director of the Lister Institute of Preventive Medicine?—Yes.

11631. Chairman of the Anti-Typhoid Inoculation Committee, appointed by the Secretary of State for War?—Yes.

11632. A member of the Advisory Committee for the Investigation of Plague in India, appointed by the Secretary of State for India?—Yes.

11633. A member of the Tropical Diseases Committee of the Royal Society?—Yes.

11634. And you were formerly Professor of Physiology in the University of Melbourne?—Yes.

11635. At present your principal post is that of Director of the Lister Institute of Preventive Medicine?—That is the only post I hold.

11636. I think you appear before us at the request of Professor Starling's Committee of Delegates of Medical and Scientific Societies?—I was asked by that committee to attend in order that the evidence should not be repeated over and over again, their object being to arrange which persons would be most suitable to present particular pieces of evidence.

11637. I am afraid it is impossible at this stage of our inquiry to hope that everything you tell us is something that we have not heard before, but no doubt there is a great deal that we shall learn from it. You propose to give us evidence under several different heads, and the first head, I see, you propose to speak about is the relation of experiments on animals to the knowledge of the causation of infectious diseases?—Our knowledge of the causation and control of them.

11638. Would you give us your views upon that point, and we will interrupt you if we think it necessary at any point?—Our knowledge of the causation of infectious diseases has been gained by experiments on animals. By the same method has been discovered the means whereby the causal agents exert their injurious influence on the body, and the means whereby the animal body defends itself against attack. I am unable to conceive any other method by which this knowledge could have been gained. It is only by the employment of the experimental method that medicine, like other sciences has been enabled to emerge from quackery.

11639. Is not that rather a strong phrase?—I am using "the experimental method" as a philosophic term.

11640. I meant the word, "quackery," which rather infers that all knowledge not discovered by the experimental method is quackery?—By "quackery" I mean practice not based upon knowledge.

11641. All knowledge derived by clinical observation you think is quackery?—But the experimental method includes that.

11642. If you include clinical observation in the words "experimental method," I understand what you mean?—That emerges from the next sentence.

11643. When you speak of the experimental method, you do not mean the experimental method on animals?—Not exclusively. Since the function of medicine is the treatment of disease—*i.e.*, of derangement of functions in living organisms, the only possible way in which the experimental method can be applied to the study of medicine is by observation and experiment upon living beings. That, of course, includes clinical and pathological observations upon man. The fundamental conception of the nature of infectious diseases we owe to Pasteur, who established the truth of his conception by experiments upon animals. Pasteur first showed, in a series of epoch-making researches into the nature and causation of fermentations, that each fermentation (*e.g.*, alcoholic lactic acid, acetic, etc.) was due to the observation of a specific micro-organism. If the germs of one particular organism were sown in a nutrient fluid the products of one particular fermentation resulted. His experience on this subject led him to the great generalisation that infectious diseases might themselves be interpreted as particular fermentations, and as due to specific micro-organisms. By a series of masterly experiments upon animals he established the truth of his hypothesis in the case of anthrax, chicken cholera, and swine erysipelas. These results of Pasteur's may be regarded as the foundation of the whole modern study of contagious diseases both in man and in animals; and their extension by Pasteur and his pupils, and by bacteriologists and pathologists all over the civilised world, has led to the discovery of the causation of most of the infectious diseases to which man is liable. It can hardly be disputed that if we are to acquire control over any disease we must have knowledge of the agent which is responsible for its production, and that if we are to frame measures to hinder the ravages of any disease, we must study (1) the life history of the micro-organism which is the exciting cause of the disease; (2) the conditions under which it can live and flourish; (3) the conditions which are detrimental to its existence; and (4)

Mr. C. J. Martin. M.B., D.Sc., F.R.S.
10 July 1907.

the circumstances by which we may modify its virulence. An accurate knowledge of the life history of the micro-organism in question is indispensable, if we are to trace in detail how the disease is transmitted from one individual to another, whether directly from individual to individual, or indirectly by other living organisms, or by dead material. Only by the possession of such knowledge can we hope to devise the best means of hindering the extension of epidemics. In a certain number of diseases this knowledge is already at our command, and has afforded means of stamping out these diseases from places where till recently their ravages were responsible for many deaths annually—e.g., malaria, yellow fever. Moreover, knowledge of the nature of the exciting causes, their conditions of existence, and the reaction of the animal organism to their introduction, has already led in some cases to the finding of a curative agent, and has indicated a way by which we may hope to gain curative powers over other infectious disorders. Even in certain cases where the causation of the disease was not directly established by experiments on animals, because no susceptible animal was available—e.g., in typhoid fever—the discovery of the causation of the disease in man was indirectly due to such experiments, since the experience gained by Pasteur, Koch, and others on animals with regard to the characters of specific infectious disorders, has enabled us to correlate our observations on man, so as to establish the casual nexus between the typhoid bacillus and the disease. Indeed, as a result of animal experimentation a new science can be said to have grown up, the science of infection. It is by experiment that Robert Koch and his pupils alone have during the past few years succeeded in establishing the causation of the following common human ailments—namely, tuberculosis, cholera, typhoid fever, diphtheria, erysipelas, tetanus, and pneumonia. In support of the above general statement, I will give a few instance from the history of scientific discovery during the last half-century.

11644. You have referred to the success in establishing the causation of certain common human ailments, and the first you name is tuberculosis. Will you tell us now what you have to say about that?—Amongst the inhabitants of temperate climates tuberculosis is responsible for more deaths than any other cause. Although the mortality from tuberculosis has declined greatly of late years, during 1903 58,150 persons, or 11.3 per cent. of the whole mortality, died from this cause in England and Wales. Tuberculosis is also a common disease of food animals. Up to the middle of the nineteenth century phthisis and other manifestations of tuberculosis were not recognised as connected, and although some clinicians, on the basis of their experience, suggested that phthisis was a contagious disease, this was not generally recognised. The prevailing view was that phthisis and other forms of tuberculosis were the results of constitutional peculiarities capable of hereditary transmission. It was realised that by keeping the individual in the most favourable surroundings for the maintenance of robust health, the onset of such manifestations was in many cases delayed, the explanation of such delay being that the patient had "outgrown the tendency to the disease." It was not known that the essential cause of tuberculosis was introduced from without, and, consequently, it was not recognised as a preventable disease. In 1843 Klencke* by experiments on animals, showed that tuberculosis could be conveyed from one animal to another by inoculation, and in 1865 Villemin†, by carefully-conceived and conducted experiments on animals, proved that tuberculosis was an infective disease due to a specific virus of a parasitic nature, which was introduced from without. He showed that the virus was capable of mutiplying indefinitely in the bodies of animals, and of being handed on from one animal to another by inoculation. He also demonstrated by experiments on animals the casual unity of the numerous manifestations of tuberculosis, such as phthisis, caseous pneumonia, scrofula, lupus, and joint disease, etc., and also the important fact that "grapes," a common disease of cattle, was due to the same virus.

11645. What is caseous pneumonia?—Cheesy.

11646. Why is it so called?—Because it was a pneumonia with a formation of patches of degenerated tissue of a cheesy nature. At the time of Villemin's discovery the prevailing view of the medical profession was that these diseases were the products of deranged functions. Much controversy occurred for several years, until the confirmatory experiments of Cohnheim and Salomonsen (Sitzungsberiche des Schles. Gesellsch. fur vater land Kultur. 15 July, 1877) secured the adhesion of medical opinion. In 1881 Koch, following the lines laid down by Pasteur, who, by experiments on animals, had established the cause of splenic fever in stock, discovered, isolated and cultivated a bacillus in the tissues of men and animals which had succumbed to tuberculosis. By a series of experiments upon animals Koch demonstrated this bacillus to be the virus of tuberculosis. Having ascertained the casual agent in tuberculosis, Koch (Berlin Klin. Wochsch, 1832, p. 221. Mitth. a.d. Kais. Gesundheits amte, 1884, Bd. 2, p. 22) was enabled to determine the conditions under which it could live outside the body, and to discover the paths by means of which the infective agent leaves a diseased animal and obtains entrance into a healthy one. Further, this discovery placed the casual unity of the very various manifestations of tuberculosis disease upon a sound basis, and permitted a certain diagnosis to be made in early and obscure cases.

11647. You then proceed to puerperal fever?—Puerperal fever is a disease which attacks women after parturition. After a mother has borne all the troubles of pregnancy, has passed through the pains of child birth, and is filled with happiness at the birth of an infant, she is liable to be stricken down with this terrible disease, and perhaps destroyed by it within a few days. In the years 1760-1770 puerperal fever prevailed in London and Edinburgh to such an extent that in some of the lying-in institutions nearly all the patients died; and in Paris, as late as 1866, over 25 per cent. of the women confined at the Maternité died of this disease; so that lying-in hospitals were looked upon by women of the lower classes as the vestibule of death. In England, during the years 1847-1903, 93,243 mothers died of this disease. From the time of Hippocrates down to the middle of the 19th century, with the exception of a few physicians who were more capable than their brethren of analysing their experience and drawing accurate conclusions (notably Dr Alexander Gordon, of Aberdeen, in 1795), the general view as to the causation of puerperal fever was that it was due to the suppression of the serous discharge which invariably escapes from the raw surface of the uterine wall during the few days following parturition. I mention this to show how the human intellect is prone to confuse effect with cause, when the true nature of the latter is not established. About the middle of the 19th century Semelweiss, in Vienna, and Oliver Wendell Holmes, in America, drew the attention of the profession in these places to the fact that an analysis of the experience of puerperal fever in lying-in hospitals and in midwifery practice indicated in the strongest manner that this disease was of an infectious nature, and conveyed from one woman to another by the agency of the doctor or midwife. The opinions of both of these men were not, however, generally accepted. One of the principal of opponents of Holmes' view was the Professor of Midwifery at Philadelphia in 1852. In his criticism of Holmes' paper he says: "I prefer to attribute them (the cases of puerperal fever) to accident, or Providence, of which I can form a conception, rather than to a contagion of which I cannot form any clear idea." Holmes' critics were able men, and I quote the above to show the necessity of supplying direct concrete proof of the nature of a contagion in order to satisfy the minds of most men.

11648. Holmes' opinion was not formed from experimenting, I understand?—It was formed from observation of experiments that were unwittingly performed ready for him by the doctors and nurses in lying-in hospitals. In 1878 we find the Academy of Medicine of Paris formally discussing the causation of puerperal fever. It was at this meeting that Pasteur, after listening to a variety of views as to the causation of this malady, interjected "None of those things cause the epidemic; it is the nursing and medical staff who carry the microbe from the infected woman to a

* *Untersuchungen und Erfahrungen im Gebet der Anatomie, Physiologie und Mikrologie. Wissenschaftlichen Medecin. Leipzig*, 1843. *Bd.* 1.

† *Cause et Nature de la tuberculose. Bull. de l'acad. de Médécine*, 5 Dec., 1865, & 30 Oct., 1866. *Etu dessur la tuberculose, preuves rationnelles et expérimentelles de la specificité et de son inoculabilité. Paris*, 1868

Mr. C. J. Martin. M.B., D.Sc., F.R.S. 10 July 1907

healthy one." The orator having remarked that he feared that microbe would never be found, Pasteur went to the blackboard and drew an organism growing in chains (the strepto-coccus) which he had isolated from the discharges of a number of patients suffering from puerperal fever, and from tissues of those dying of this disease. He also found the same organism in the blood obtained by a prick of the finger in similar cases, shortly before death. Pasteur believed, from analogy with his observations on anthrax and other diseases, that this organism would be found to be the cause of the disease. This was subsequently proved by experiments upon animals. Pure cultures of the organism discovered by Pasteur injected into rabbits multiplied rapidly, and spread throughout their blood, causing the death of the animal with fever and suppuration; a drop of the blood of a rabbit dying from this inoculation, if rubbed into a scratch upon another animal, occasioned its death in a similar manner.

11649. Do I correctly understand that this coccus poisons persons, and will kill persons who are not child-bearing?—Certainly. The conditions following child birth offer a very large surface for the entry of any organism; but the disease in common to all forms of wounds.

11650. You mean that the same coccus causes those diseases and others?—Yes.

11651. It is not peculiar to puerperal fever?—Not at all. The nature of the contagion in puerperal fever having been recognised, the disease almost entirely vanished from the maternity hospitals of Europe and America. The result was accomplished by avoiding every opportunity whereby the infection might be conveyed to a woman during labour, and by employing those principles of antiseptic surgery which we owe to Lister. The antiseptic system of Lister was a direct extension to wound infection of Pasteur's work on the nature of fermentation and putrefaction.

11652. Then we come to diphtheria. Will you tell the Commission what you have to say about that disease?—Diphtheria, a name introduced by Brettoneau for a series of inflammatory diseases of the throat, windpipe, and nose, associated with the development of a membranous exudation, has long been known to be an infectious disease. It is a disease more particularly of childhood, the course of which the physician found himself until recent times powerless to influence. He could only do what little was possible to diminish the sufferings of the patient, and when the larynx became obstructed, establish an entrance and exit for the respiratory air by tracheotomy, or intubation. In 1875 Klebs (*Arch. f. exper. Path. Bd. iv.*) found a bacillus hitherto unknown, in the membraneous exudation of cases of diphtheria. This bacillus did not occur alone, but associated with a variety of other micro-organisms, and it was doubtful how far this particular bacillus was responsible for the disease. In 1882 Loeffler (*Mittheillung a.d. Kais. Gesundheits amte. Bd.* 2, 1884) succeeded in isolating Kleb's organisms from the diphtheritic membrane and growing it upon solidified blood serum. Once isolated, the Klebs-Loeffler bacillus was shown by experiments upon animals (rabbits, guinea pigs, and pigeons) to produce a disease presenting a resemblance to diphtheria, including the characteristic paralysis when the animal survived the acute symptoms (Loeffler, Roux, and Yersin) (*Ann. l'Inst. Pasteur,* 1888). As had been found to be the case in man, the bacillus occurred only at the point of inoculation. This fact led Roux and Yersin (*Ann. de l'Inst. Pasteur,* 1888, 1889, *and* 1890) to the conclusion that this bacillus must produce a poison which was absorbed into the circulation. They therefore grew the bacillus in broth, and discovered that after the separation of the germs by filtration through porcelain, the fluid contained a powerful poison, which, when inoculated into animals, produced all the effects of the bacilli themselves. Thus was diphtheria toxin discovered; but, what was far more important, a method whereby a pathogenic organism exerts its deleterious effects was brought to light. Roux and Yersin's experiments also led to the discovery by Behring (*Behring and Kitasato Deutsche Med. Wochschr,* 1890. *Behring and Wernicke Feilscript f. Hygiene,* 1892), through experiments on animals, of a physiological process which is brought into play by the animal body to counteract the influence of the germs of some diseases. This process consists of the production, through the agency of its own tissues, of a substance which neutralises the poison produced by the microbes. When this substance is manufactured by the cells of the animal in sufficient quantity and with sufficient rapidity, the animal is able to successfully resist the onslaught of the diphtheria bacillus, and recovers from the disease. These observations, in their turn, have led to the development of curative means in imitation of nature's processes (serum-therapy), of great value to humanity.

11653. We now come to tetanus?—Tetanus or lock-jaw is a malady common to man and most animals. Of the latter the horses are particularly susceptible to this disease. The sufferings caused by the intense muscular spasms, which are characteristic of the disease, renders tetanus one of the most horrible maladies one can witness. The mortality from tetanus is 80 per cent. In fatal cases the spasms involve the respiratory muscles to such an extent that the patient dies of suffocation. Since the introduction of the antiseptic treatment of wounds the incidence of this disease has been greatly reduced, but formerly it was much more frequent. It has long been known that tetanus was particularly prone to follow badly lacerated wounds, especially such as became contaminated with soil or road dirt. The danger of tetanus after gunshot or other wounds in battles was formerly very considerable, and when once the infection started in an extemporised military hospital it spread so extensively as sometimes to infect every-one of the wounded. According to the German statistics in the Franco-German war, tetanus occurred in 0.35 per cent. of all wounds (*quoted by Vaillard article Tetanus maladies commes à l'homme et aux animaux, Paris,* 1906, *p.* 351). Tetanus has also been responsible for a heavy infantile mortality, especially in maternity hospitals. In the Rotunda Hospital, at Dublin, up to 1882, of 17,650 infants born, 2,944 died of this disease (*quoted from Clarke by Vaillard, loc. cit. p.* 348). This mortality could have been entirely prevented if the cause and means of spread of the infection had been known. That tetanus was a disease due to infection by a specific micro-organism was conjectured from the time that the microbial causation of anthrax and chicken cholera had been established by Pasteur. The infective nature of the disease was established by Carle and Rattone in 1884 (*Studio sperimentali sull' etiologia del tetanos. Giorn. della R. Acad. di Medicina di Torino,* 1884), who succeeded in producing tetanus in animals by injecting a small quantity of the pus from the wound of an animal suffering from this disease. The discovery of the causal agent was not, however, determined until 1889, when Kitasato (*Deutsch Med. Wochschr,* 1889, *No.* 31) succeeded in isolating and cultivating the same bacillus from the pus of wounds in cases of tetanus, and proved, by the injection of pure cultures of the organisms into animals, that it, and it alone, occasioned the disease. This bacillus had been previously seen by Nicolaier in 1884 (*Deutsch Med. Wochschr,* 1884, *No.* 52), in the local wound of animals which he had succeeded in infecting with tetanus, by the inoculation of a minute fragment of garden earth, and also by Rosenbach (*Arch f. Klin Chir,* 1885), in the pus from a wound in the case of a man suffering from tetanus. These discoveries explained how the infection of tetanus could be conveyed from one wound to another, and why soiling of wounded surfaces with earth is particularly liable to occasion the disease. Having isolated the bacilus of tetanus, Kitasato was enabled to precisely ascertain, firstly, where and under what conditions it flourished in nature; and, secondly, those conditions which destroyed it. The bacillus of tetanus remains in the situation at which it finds entrance into the tissues. Under suitable conditions it multiplies in the wound, and produces its characteristic effect upon the nervous system by means of a poison which it secretes. By growing Kitasato's bacillus in broth and filtering through porcelain, which does not admit the organisms to pass, but only the soluble products of their activity, Faber, in 1890 (*Bertin Klin Wochschr,* 1890, *p.* 717), obtained a poison, minute quantities of which, when injected into animals, produced the disease (1-100,000 of a cubic centimetre). All these investigations have afforded knowledge of the cause of tetanus, the life history of the causative bacillus, the conditions favourable or otherwise to its existence, the means whereby it may be destroyed, and the manner in which the symptoms of the disease are brought about. By taking advantage of this know-

ledge, epidemic outbreaks of the disease can be absolutely prevented, and the great majority of wounds where contamination with soil has rendered them liable to infection with tetanus bacilli can be successfully dealt with. In the recent South African War only three cases of tetanus occurred. Further, the animal experiments of Behring and Kitasato (1890) (*loc. cit.*) showed that by repeated small but increasing doses of the soluble tetanus toxin, animals can be rendered immune to this poison, and that the serum of such highly immunised animals renders inoffensive the tetanus poison with which it is mixed. The serum of horses which have been gradually accustomed to this poison until they support, without ill-effects, quantities many thousand times that required to kill horses not so treated, is a valuable therapeutic agent in human and veterinary surgery. This subject will, however, be referred to in greater detail later.

11654. You now have something to tell us about plague?—Plague is a disease of great antiquity, and previously seen by Nicolaier in 1884, in the local wound some of the earliest human documents extant record the ravages of this pest. During 1905, 1,040,429 persons succumbed to plague in India. Over 350,000 deaths occurred in the Punjab alone (*official returns*). In some of the villages of this province 75 per cent. of the population were destroyed in two years. The mortality amongst Asiatics varies between 70 and 80 per cent., and amongst Europeans at the present time it is over 35 per cent. of those attacked. As long as the causation of plague was not comprehended, and the means by which it is spread were unknown, suitable preventive measures could not be rationally prescribed. Consequently, even in recent times, wealth and human effort have been squandered in directions that have led to no useful result. The constant association of a mortality of rats and mice, with outbreaks of plague amongst human beings, has been forced upon the minds of many ancient people, and is found to exist among many primitive races of mankind at the present time. The true significance and importance of this observation could not, however, be realised until the causation of the disease was discovered by Yersin and Kitasato (*Lancet*, 1894) in Hong Kong in 1894. These observers found a bacillus constantly present in the swollen lymphatic glands (buboes) of patients suffering from the disease, and they succeeded in growing it upon artificial media. Inoculation of the cultures of this organism into animals reproduced the disease with all its characteristic symptoms. Once the cause of the disease was known, it was easy to determine that the disease from which rats and mice simultaneously suffered was also plague. All the conditions, favourable and unfavourable, to the existence of the infective agent, could now be studied, and the means whereby the infection leaves the bodies of persons or animals dead of the disease, could be determined. The relationship in time and space between human outbreaks and disease in rodents could be worked out, and the influence of epidemics amongst rats in the spread of the disease among human beings determined. The relationship of rat plague to human plague has been found to be of such a character as (taking into consideration the small extent to which bubonic plague is infectious from man to man) to indicate in the strongest manner that the spread of the disease in man is conditioned almost entirely by the occurrence of plague amongst rats in his vicinity. The Commission at present investigating the question of the spread of plague in India, have, by extensive experiments upon animals, succeeded in showing that the infection is carried from rat to rat by the agency of the fleas infesting these animals (*J. of Hygiene*, 1906 *and* 1907, *special numbers*). By the same agency they have been able to produce epidemics amongst other animals, guinea pigs and monkeys; whereas all other means failed to give rise to the epidemic spread of the disease. The Indian rat flea also feeds upon man when his natural prey is not available, so that a possible, and indeed probable, means whereby the infection is carried from rats suffering from the disease, to mankind has been established. Further experiments carried out in houses or huts, where many cases of plague occurred, have shown that animals (guinea pigs or monkeys) are attacked by the disease when placed in such infected huts, without protection from fleas; but if the simplest means is adopted to prevent the fleas from reaching the animals, by a gauze covering, or a layer of sticky paper wider than a flea can jump, or by suspending the cage at a distance from the floor greater than a flea can leap, they have in no case contracted plague.

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

10 July 1907.

11655. Whose are these experiments with fleas?—The experiments of the present Commission which is investigating the plague in India, of the Advisory Committee of which I have the honour to be a member.

11656. Do these fleas which carry the plague from one to another get the plague themselves?—No, they do not suffer in health apparently. The plague microbes merely multiply inside their alimentary canal, without apparently detrimentally affecting them in the least.

It need hardly be insisted upon that the complete comprehension of the spread of the disease under natural conditions is essential to successfully devise preventive measures. Without such knowledge our efforts will, in all probability, be misdirected. A knowledge of the causation of plague has enabled a useful method of protective inoculation to be devised. Efforts towards the production of a curative serum have unfortunately, so far, been disappointing, as the means employed have not produced an anti-serum of sufficient potency.

11657. Your next head of evidence is the importance of experiments on animals in the diagnosis of infectious diseases?—The value of a means of arriving at an early diagnosis in the case of infectious disease of man and animals is considerable, because the physician or veterinary surgeon is, as a rule, unable to form a diagnosis until the disease has developed. This may mean a delay of weeks, or even months, during which precious time is lost, and precautions to prevent the spread of the disease omitted. Moreover, in mild or latent cases of a disease, it may be quite impossible to arrive at a diagnosis by ordinary clinical means. The advantages of early bacteriological diagnosis are not confined to the patient, but are of importance to the community, or the owner of stock or stable, for upon the early recognition and segregation of cases of infectious maladies, the probability of successfully stamping out the disease depend. Mild or abnormal cases of disease may be equally endowed with the power of spreading the infection. Recent researches into the epidemiology of diphtheria, typhoid, and cholera, have indeed proved, that persons convalescent from these diseases and in all respects perfectly healthy, may be innocent agents distributing broadcast these various infections. In many cases a bacteriological diagnosis of a disease can only be made by direct appeal to animal experiment; but in quite a number a simpler method by which this is avoided, but which has been arrived at in the first instance by experiments upon animals, can be employed. As instances of such methods I cite: (1) The recognition under certain conditions, of tuberculosis, anthrax, relapsing fever, diphtheria, syphilis, gonorrhœa, plague, and sleeping sickness, by observations upon the morphological staining and growth characters of the organisms contained in the material submitted to examination. (2) By taking advantage of the fact that the human and animal body when infected with certain diseases, *e.g.*, typhoid fever, cholera, and malta-fever, elaborates substances in the blood which have the property of causing the individual organisms of these diseases to aggregate together into clumps, so-called agglutinins. As this agglutinating action is within certain limits only exercised upon the particular species of microbe which is responsible for the disease, a diagnosis may be arrived at. For this purpose a single drop of blood from the patient is adequate. (3) In the case of cholera and typhoid infections a further substance is present in the blood serum, which has the power of killing and dissolving up the respective bacilli. This action is specific, so that the test applied with a few drops of blood can be used for diagnosis. (4) Nos. 2 and 3 can be applied in the reverse direction, viz., to identify microbes suspected of being typhoid or cholera, which have been separated from water or the dejecta and other excretions or discharges from the human body. In this case cultures of these organisms are submitted to the action of a small quantity of the serum, obtained from an animal immunised against infection with typhoid or cholera microbes. (5) The diagnosis of tuberculosis in cattle and of glanders in horses, in the early stages of the disease, when it cannot be recognised by clinical signs, can be made by the infection of a small quantity of tuberculin or mallein respectively. Tuberculin and mallein are the products which are formed by the growth of tubercule and glanders bacilli

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

10 July 1907.

in broth. The organisms themselves are killed by boiling, and are then removed by filtration. Tuberculin and mallein in the quantities employed produce no effect when injected under the skin of healthy animals, but if the animals be suffering from the corresponding diseases, fever, and in the case of mallein, local swellings occur, thereby enabling a diagnosis to be made. They are extensively used to ascertain the existence of tuberculosis in dairy cattle, glanders among horses in large stables in the early stages of the disease. In the cases of glanders and tuberculosis the disease may exist for a long time in a latent form, the animals appearing during this stage to be in perfect health. In such animals the disease is liable to assume an acute and highly infective character. It is, therefore, of great advantage, especially to the owner of valuable stock, to be able to recognise the disease in this form, so that the infected animals may be removed from the vicinity of healthy stock.

11658. Your third head of evidence is the preventive and curative measures discovered by experiments upon animals, and requiring the inoculation of animals for their production and standardisation?—I begin with hydrophobia (rabies). Pasteur discovered that it was possible to modify the virulence of the microbes of chicken cholera and anthrax by growing them outside the animal body under particular conditions. He also found that the inoculation of such attenuated cultures gave rise to merely slight *malaise*, from which the animal speedily recovered. On subsequently inoculating those animals which had received cultures of diminished virulence with microbes of full virulence, he discovered that they had become possessed of a marked degree of resistance to the disease. On the basis of this observation, Pasteur, by carefully controlled experiments on animals, devised a method of protective inoculation against chicken cholera and anthrax. This Pasteurian vaccine has been extensively employed in many countries, and has been the means of saving wealth to stockowners. Pasteur had continuously before him the possible application of his discoveries in the sphere of animal diseases to the alleviation of human suffering. Amongst those diseases which had particularly appealed to his imagination was the tragedy of hydrophobia. In the case of an individual bitten by a dog suffering from rabies, no remedy was available apart from local cauterisation. The patient remained in suspense for months fearing the onset of this fatal disease. Reasoning from the analogy afforded by his previous discoveries, Pasteur thought it might be possible to take advantage of the interval between the infection and the development of the symptoms in hydrophobia to produce in the person bitten a sufficient resistance to the disease to prevent its development altogether. Pasteur commenced this inquiry in 1881 in conjunction with Roux, Chamberland and Thullier (*Comptes rendus*, 1882). His first efforts were directed to the isolation of the casual agent. In this he was unsuccessful, and it has not yet been accomplished. He discovered, however, that the virus existed in the nervous system of rabid animals in a pure form, and that it became attenuated by slowly drying it for two or three weeks at a temperature of 20 deg. C. He next showed that by previously inoculating his attenuated virus under the skin of dogs, these animals did not contract the disease when subsequently bitten by rabid dogs. Pasteur had shortly before shown that the inoculation into the brain of a dog of a minute portion of the nervous system of an animal which had succumbed to virulent rabies, invariably gave rise to the disease. Nevertheless, previous treatment of a dog with his attenuated virus was able to prevent the development of the malady in this case also. Having shown that it was possible to prevent the disease by treatment, previous to the inoculation with virulent virus, he tested the influence of his method when applied during the period between the infection and the development of the disease (*Pasteur, Chamberland and Roux, Comptes rendus*, 1885). The results were entirely successful, and in 1885 Pasteur was induced to try his method upon the human subject. Of Pasteur's first 350 patients, only one died. This was a little girl horribly bitten about the head and face 37 days before she arrived in Paris. Pasteur felt constrained to attempt his treatment upon this child, although the severity and situation of the bites, and the long interval before treatment began, rendered the case hopeless. Since then anti-rabic inoculation has been employed all over the civilised world, wherever the disease has existed. There are at present 51 institutes for the carrying out of the treatment, distributed over Europe, America, Asia, and Africa. Between 1886 and 1905 more than 150,000 persons have been inoculated. The result of the treatment at the Pasteur Institute, Paris, are published each year in the "Annales de l' Institut Pasteur" under three categories.

11659. You say there are 51 institutes. Can you tell us how many there are in the United Kingdom?—None. We have the good fortune to live on an island, and it was possible to get rid of hydrophobia by muzzling the dogs.

Those three categories are:—(a) Persons bitten by dogs, etc., proved to be suffering from rabies by animal experiment; (b) Persons bitten by dogs, etc., certified by veterinary surgeons to have rabies; (c) Persons bitten by dogs, etc., suspected to have rabies. The number of persons treated at Paris, and the mortality since the introduction of the treatment is given below:—

Year.	Cases Treated.	Deaths.	Mortality per cent.
1886	2,671	25	0·94
1887	1,770	14	0·79
1888	1,622	9	0·55
1889	1,830	7	0·38
1890	1,540	6	0·32
1891	1,559	4	0·25
1892	1,790	4	0·22
1893	1,648	6	0·36
1894	1,387	7	0·50
1895	1,520	5	0·33
1896	1,308	4	0·30
1897	1,521	6	0·39
1898	1,465	3	0·20
1899	1,614	4	0·25
1900	1,420	4	0·35
1901	1,321	6	0·38
1902	1,105	2	0·18
1903	628	2	0·32
1904	755	3	0·39
1905	727	3	0·41

The figures for the various other anti-rabic institutions are available, and the results are in most cases equally satisfactory. In the 150,000 persons treated in different parts of the world the mortality has been less than 1 per cent., and in most institutes less than ½ per cent.* Rabies is a fatal disease, but it is impossible to estimate exactly how far persons bitten by animals known, or suspected to have been suffering from rabies, are liable to develop the disease. The reason why this cannot be done is that the circumstances, situation, and nature of the bites vary so greatly in different cases. I have gathered together all the reliable information I could get to form an estimate. Bouley, in an official inquiry into the history of 320 cases made under the Second Empire, found that 40 per cent. of the persons bitten contracted the disease. Leblanc, 1878-1883, head of the sanitary department of the Prefecture of Police in Paris, concluded from an examination of 515 cases that it was 16 per cent.; Faber (Wurtemberg), from 145 cases, 20 per cent.; Werner (Vienna), (1879-1886), from 429 cases, 11.8 per cent.; and Hogyes (Buda-Pesth), from 470—9.3 per cent. That was the case

* *The average mortality of the 150,000 cases indiscriminately collected by myself from all the sources readily accessible to me is ·5 per cent.—C. J. M.*

when I prepared my statement; but including later details Hogyes (Buda-Pesth) concluded from 855 cases that it was 13.9 per cent. If all the cases are added up together, and the number of deaths, the average comes to 17.9 per cent. as the estimated mortality when bitten by a rabid dog. That estimate is based upon 2,264 cases.

11660. I thought these were percentages of the persons bitten who had contracted the disease. Is this last figure the average mortality?—Yes. I have added the number of cases observed by each man together, and the number of deaths returned by each man.

11661. (*Sir John McFadyean.*) Of persons untreated?—Yes, this is of persons untreated.

(*Chairman.*) It is not quite clear. You begin by saying that Bouley, in an official inquiry into the history of 320 cases made under the Second Empire, found 40 per cent. of the persons bitten contracted the disease.

(*Sir John McFadyean.*) They all died.

11662. (*Chairman.*) It does not say so. That is assumed?—In the paragraph before I stated that rabies is a fatal disease.

11663. (*Sir John McFadyean.*) You might say "invariably"?—I will put, if you think it is stronger, "invariably fatal."

11664. (*Mr. Tomkinson.*) Rabies in the dog?—No rabies in man.

11665. Do you not call it hydrophobia?—If you like I will call it hydrophobia—hydrophobia is an invariably fatal disease in man.

11666. But dogs do not have hydrophobia; the dog has rabies?—Rabies is one name for the disease, and hydrophobia is another.

11667. Is it correct to use the word hydrophobia in the case of a dog?—I think so, certainly.

11668. I thought not. I thought the dog did not have the fear of water.

11669. (*Sir William Collins.*) Do all these figures refer to the period prior to inoculation?—No; some figures are collected later; but they are all of cases which have not undergone treatment.

11670. But your figures in the Table start with the year 1886?—Yes.

11671. Is that what you regard as the commencement of the inoculation period?—Yes; but everybody does not undergo treatment for rabies even now.

11672. Would you be so good as to answer that question? Do you regard 1886 as the period from which the inoculation method was introduced?—Certainly.

11673. Do the figures which you have just given us in regard to the number of cases that were bitten and attacked relate to the pre-inoculation period?—Not entirely.

11674. Do all except those that you have just added with regard to Buda-Pesth?—No, not entirely.

11675. It seems desirable to separate those, because there may be a question whether they are all of the pre-inoculation period or whether you are adding some cases now which though not treated belong to the post-inoculation period?—In the case of Buda-Pesth that is so.

11676. Then will you be so good as to indicate in what cases you are dealing with the post-inoculation period?—I am not certain off-hand about Faber's at Wurtemberg; but I believe those were of pre-inoculation date.

11677. Then are there any except the additional cases which you have added from Buda-Pesth, which were of the post-inoculation period?—I am not sure about Faber's, without looking the thing up again.

11678. That is the only exception?—Obviously for the others I put the dates in

11679. I gathered from the dates that you were purposely obtaining cases which were pre-inoculation cases; then when you added the Buda-Pesth cases I wondered whether they related to post or to pre-inoculation. I understand now that they relate to post-inoculation?—Yes, but untreated.

11680. (*Sir John McFadyean.*) I suppose you really took all the statistics that you could find on that subject?—Yes.

11681. You did not select them because they were of the pre-inoculation period?—No.

11682. There have been no records made of those of Bouley and others?—No.

11683. You could not find any in the literature to the same extent?—No.

11684. Are you sure that the Pasteur treatment only began in 1886. It would be rather extraordinary if in the first year's treatment 2,671 persons were treated. Were not those the first published statistics merely?—Yes, you are right; I have previously stated that Pasteur commenced to treat patients in 1885. The return for 1886 includes the year before, too.

11685. (*Sir William Collins.*) But you state the mortality since the introduction of the treatment began with the year 1886?—Yes, that is the first year for which the returns were published and are available.

11686. (*Sir Mackenzie Chalmers.*) But still they are untreated cases?—Yes.

11687. Does it make any difference whether they were bitten before or after the invention, as long as they were not treated?—I imagine not.

11688. I do not know. It might?—I see no reason why it should.

16689. There is just this point, that the more severe cases might be treated, and the untreated cases would be the more doubtful cases?—That might be so, of course. But that will be in favour of my argument.

11690. I know?—I can only deal with the figures as they are available.

11691. (*Sir William Collins.*) And it might not be so?—It might not be so.

11692. (*Sir John McFadyean.*) There is just one other question I should like to ask you. I should like to be quite clear whether these statistics relate to people who were bitten merely by dogs suspected of rabies; because many returns distinguish between persons bitten by dogs suspected of rabies and those bitten by dogs experimentally proved to have been rabid or certified by a veterinary surgeon to have been rabid. The older statistics were not experimentally proved. They were on the opinion of the veterinary surgeon. The most careful statistics, so far as I can judge, are the last ones from Buda-Pesth, from Hoygés. He was the director of one of the biggest Pasteur Institutes in the world, which is situated in Buda-Pesth. And in Hungary hydrophobia is particularly important as a disease.

11693. (*Sir William Collins.*) But would the figures which appear in your statement be correct, that of the 470 case of Hogyes an attack rate of 9.3 per cent. was observed?—That was in the first 470 cases.

11694. Would you give us separately what the additional cases are which you now add which produce an attack rate of 13.9 per cent. in the total?—I cannot do it now.

11695. It will complete the statement?—Yes.

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

10 July 1907

In searching the literature in order to comply with the request of the Commissioner, I have discovered further figures relating to the mortality amongst persons bitten by dogs judged to have been suffering from rabies and not treated by the Pasteurian inoculations. The list giving date and place of observations and source of information is as follows:

Figures collected by.	Locality.	Date.	Number of Cases.	Number of Deaths.	Mortality (per cent.)	Source of Information.
Faber	Wurtemberg	1846	145	28	20	Hogyés article "Lyssa" Nothnagel's Spezielle Pathologie u. Therapie Bd. V. T. 5. p. 829.
Bouley	France	1860–70	320	128	40	Life of Pasteur. Valerie-Radot English translation, p. 267.
Leblanc	Department of Seine.	1878–1883	515	81	16	Menetrier, article "La rage" Maladies Communes a l'homme et aux animaux, Paris, 1906.
Werner, Vienna General Hospital	Vienna	1879–1886	429	44	10·3	Menetrier, article "La rage" Maladies Communes a l'homme et aux animaux, Paris, 1906.
Hogyés	Hungary (Official enquiry, Minister of the Interior)	1885–1888	470	44	9·3	Hogyés *loc. cit. supra.*
Hogyes	Hungary (Official enquiry, Minister of the Interior)	1890–1895	985	147	14·9	Hogyés *loc. cit. supra.*
Kurimoto	Nagasaki	1892	67	21	31·3	Kurimoto. Virchow's, Arch. 1899. Bd. 158. p. 148.
Kurimoto	Nagasaki	1893	145	15	10·3	Kurimoto. Virchow's, Arch. 1899. Bd. 158. p. 148.
Kurimoto	Nagasaki	1894	51	9	17·6	Kurimoto. Virchow's, Arch. 1899. Bd. 158. p. 148.

Total cases	3,127
Total deaths	517
Average mortality (per cent.)	16·5

I should like to interject that I have not selected these figures; they are simply all that are available to me for basing a judgment upon as to what the chance of death is if you are bitten by a mad dog. The average of the above is 17 per cent., and is the best estimate that I can arrive at. Assuming this as correct, and taking the mortality of patients treated as high as 1 per cent., the method of Pasteur has in 20 years saved upwards of 25,245 persons from the horrible disease of hydrophobia, and all the attendant suffering to their friends and relations, as well as relieving 148,500 persons of the awful suspense for six months, after having been bitten by a dog suspected of rabies.

11696 (*Chairman.*) You come next to serum therapeutics in connection with experiments on animals?—Many organisms, and notably those of diphtheria and tetanus, exercise their harmful influence by the secretion of a soluble poison or toxin, which is absorbed from the seat of infection and circulated in the body of the infected animal. One of the means of defence against the invasion of such organisms which is possessed by the animal body, is the capacity to manufacture and set free in the blood stream substances which combine with the toxins, and so render them inert. By habituating a large animal, such as a horse, to the action of the toxin in increasing quantities, some cells or fluids of its body can be thereby stimulated to produce antitoxins, which are then thrown into the blood stream. These antitoxins, when they have reached a sufficient strength, may be employed as a remedy for the disease in man or animals. Von Behring must be regarded as the founder of serum therapeutics. In 1890 he, with Kitasato (*loc. cit.*), showed that the blood serum of an animal, which had been immunised against tetanus, was capable, when injected into other animals, of protecting them, not only against poisoning by the tetanus toxin, but also against infection with living tetanus bacilli. He also proved that under certain conditions a curative action could be demonstrated in animals which already presented symptoms of tetanus infection. Similar though less striking results were described in the case of diphtheria. By showing that the horse reacted to repeated and increasing injections of diphtheria toxin, by manufacturing and circulating in its blood such quantities of antitoxin that a few cubic centimetres of their serum was possessed of sufficient curative power to be useful in the treatment of diphtheria in the human subject, Roux (*loc. cit.*) and Ehrtich first brought the subject from the experimental to the practical stage.

11697. How are the antitoxins prepared?—For the preparation of antitoxins on a large scale the horse is the animal now almost exclusively used. The horse can be suitably immunised against tetanus, diphtheria, and many other diseases and intoxications. In the case of tetanus, diphtheria, and dysentery the sera obtained attain to a very high antitoxic value.

11698. What precautions are taken in the selection of the horses for the preparation of antitoxin?—The horses are selected by a skilled veterinary surgeon. They must be free from all signs and symptoms of disease. Every horse is tested for latent glanders with mallein, and even a suspicion of a reaction is regarded as a sufficient basis for the rejection of the animal. If the animal has satisfactorily passed the test, he is received into the establishment, but is isolated and kept under observation for some time. Having passed through this period of probation, the animal is admitted into the stables, and the process of immunisation is commenced. During the process the animal is kept under the strictest observation—his temperature is duly registered, and the greatest possible care is taken in regard to his comfort and feeding.

11699. (*Sir William Church.*) Ought you not to qualify that statement by saying where these precautions are taken? It is rather a bold thing to say that they are taken everywhere. You have no means of knowing how strictly the precautions are carried out, except in certain establishments?—I know that these precautions are taken in our own institute; and I think I can safely say that they are taken in the other places where sera are made in this country—that is in Burroughes and Wellcome's.

11700. (*Chairman.*) Is that from what has been told you?—No; I have seen the way they work.

11701. You have visited their place?—Yes.

11702. (*Sir William Church.*) Would it not be safer to say that in this country the precautions are taken?

11703. (*Chairman.*) You mean in this country; you do not mean all over the world?—I am not aware of all over the world.

11704. At any rate, we had better confine ourselves to this country, because that is all we have to inquire into.

11705. (*Dr. Wilson.*) May I ask, do you use mallein after the horse is bled, for the production of serum? You always use it before; but do you ever use it while the horse is in the institute for experiment?—No. The mallein test is performed before the horse comes to us by the veterinary surgeon.

11706. What would be the effect of using it if used after the horse has been experimented on, after the toxin has been used for a horse that has been bled for some time?—I do not think there would be any effect.

11707. (*Chairman.*) At any rate, in your evidence you speak with confidence about your own institute?—Certainly.

11708. And as to other institutes in this country, I understand it to be your belief, from personal observation, that the process is carried out strictly there in the same way?—Certainly.

11709. Will you describe the process of immunisation?—The animal is treated with increasing doses of the particular poison. The toxins are injected subcutaneously, intramuscularly, or intravenously. At first either very minute doses of weak toxins, or toxins which have been modified by chemical agents, or in others ways, are employed. In the case of tetanus, in the early stages the toxin is usually modified by being treated with iodine. The first injection of the toxin may be followed by swelling at the site of inoculation, loss of appetite, general malaise, and rise of temperature. When these have passed off the animal receives a second rather larger injection, and in this way the quantity of toxin is increased until, within a few months, the horse is capable of tolerating many thousand multiples of what would be a lethal dose if given as a first injection. When the serum has reached the strength suitable for clinical use, blood is withdrawn from time to time by venesection. All the processes connected with immunisation are carried out under the strictest antisepsis.

11710. What precautions are employed in preparing the different sera?—The vessels containing the sterile blood are removed into a small isolated building used for this purpose only. The serum, when it has separated from the clot, is decanted into sterilised vessels, the usual bacteriological precautions being taken to prevent the admission of extraneous germs. To the serum thus obtained 0.2 to 0.3 per cent. carbolic acid is added. As a final precaution the serum is passed through a Berkefeld filter. It is then in a condition to be put into the small phials in which it is sent out for use. Before this is done, however, it is subjected to the following tests:—1. For sterility. It must be germ-free. 2. For absence of toxicity. 3. For antitoxic value. This much reach a required standard. The last two tests are carried out on small animals. The serum is also kept for a certain time, during which the horse remains under observation; if during this time the animal shows any signs of illness the serum is thrown away. It must be clearly understood that antitoxin is a substance which circulates in the blood of immunised animals, and which has been elaborated by the animal body. It has the property of rendering inert the particular poisons with which the animals were treated. It is a chemical substance which neutralises these poisons. Antitoxins are produced when a variety of poisons (all, however, of a complex nature) are introduced into an animal in suitable quantities. This property of stimulating the productions of antitoxins by the animal body is not confined to the poisons produced by the organisms of disease. Snake poisons, most ferments, and several vegetable poisons also give rise to the production of anti-bodies, which neutralise the particular poison injected. Antitoxins exert no influence upon the disease germs themselves, bnt only upon their products; the bacillus of diphtheria grows excellently well in diphtheria antitoxin. Unfortunately, the useful application of antitoxic serum-therapy is at present limited to a comparatively few diseases. The most important of these are diphtheria, tetanus, and epidemic dysentery. The value of serum-therapy in snake bite is limited, owing to the fact that the horse will not manufacture and store in its blood anti-venom beyond a certain amount. Once a certain concentration of antitoxin is reached the animal ceases to react in this way to further injections of venom. Moreover, a different antitoxin is required for nearly every species of snake, which imposes practical difficulties in the way of this treatment.

11711. You have prepared, I think, various tables showing the curative value of diphtheria antitoxin?—At the Medical Congress at Buda-Pesth in 1894 Roux communicated the results of the treatment with antitoxin of 300 cases of diphtheria in the Paris Hospital. The mortality of those treated with antitoxin was 24 per cent., as against 60 per cent. in the non-treated. In another hospital in Paris, where antitoxin was not yet used the mortality was 80 per cent. The experimental and clinical data, and favourable statistics brought forward by Roux, led to the trial of this method of treatment for diphtheria in all civilised countries. Diphtheria antitoxin came into use in England in 1895, and immediately a fall in the case mortality in this disease was noticed in those institutions where it was administered. I give some instances of the case mortality from diphtheria before and after the employment of the antitoxic treatment:—

PARIS HOSPITAL (HERICOURT, 1899).

Year.	Case mortality per cent.	
1893	45	
1894*	31	
1895	12	Average 14 per cent.
1896	15·2	
1897	13·2	
1898	14·5

1900	—	12·01
1901	—	12·5
1902	—	11·0
1903	—	9·7
1904	—	10·1
1905	—	8·3

* Commencement of the Antitoxin period.

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

10 July 1907.

CASE MORTALITY OF DIPHTHERIA FOR THE COUNTY OF LONDON. Calculated from the curves in Report of the Public Health Committee, L.C.C., 1904.

Year.	Per cent.
1892	21·6
1893	24·9
1894	23·2
1895 (Antitoxin introduced)	20·4
1896	19·9
1897	16·6
1898	15·0
1899	13·3
1900	12·1
1901	11·6
1902	10·8
1903	10·0
1904	10·0

CASE mortality from Diphtheria in 31 of the largest English towns from 1894 to 1904. (Armstrong, 33rd Annual Report of the M.O.H. Newcastle-upon-Tyne for 1905. Appendix E).

	Per cent.
1894	30·5
1895	33·1
1896	31·3
1897	25·1
1898	25·4
1899	25·2
1900	22·7
1901	22·0
1902	20·8
1903	17·7
1904	18·0

In the County of London a large proportion (65 per cent.) of cases of diphtheria are removed to the Metropolitan Fever Hospitals, where nearly every case is adequately treated with antitoxin.

In the provincial towns the proportion of antitoxin-treated cases to total cases is, I believe, considerably less.

CASE mortality in New York City from Diphtheria from 1891 to 1899. (Billings, New York Medical Journal, 1900).

Year.	Cases.	Deaths.	Mortality per cent.
1891	5,346	1,970	36·7
1892	5,184	2,196	40·6
1893	7,021	2,558	36·4
1894	9,641	2,870	29·7
1895 *	10,353	1,976	19·1
1896 †	11,399	1,763	15·4
1897	10,896	1,590	4·6
1898	7,593	923	12·2
1899	8,240	1,087	13·1

* Antitoxin introduced.
† Use of Antitoxin became general.

VIENNA.—Siegert Jahrbuch for Kinderheilkunde, 1902.

4,894 cases of diphtheria.

Year.	Mortality per cent.
1892–4	41
1895–7	20

BUDA-PESTH.—St. Ladislaus Hospital (Gertoczy, Wiener Klinische Rundschau, 1896).

Year.	Number of cases.	Mortality per cent.
1893	213	48·8
1894	227	44·9
1895*	401	19·9

* Commenced using Antitoxin.

RUSSIA.—St. Petersburgh Hospital, Rauchfuss. (XII. International Medical Congress, Moscow, 1897. Centralb. f. Bakt. Vol. 25.)

Year.	Cases.	Mortality per cent.
1870–4	304	59·5
1875–9	610	48·5
1880–4	1,425	58·1
1885–9	735	55·2
1890–4	792	55·2
1895–6*	801	22·7

* Commenced using Antitoxin.

THE results for 51 Russian Provinces for 1895 and 1896 (Rauchfuss *loc. cit.* were as follows:—

—	Number.	Mortality per cent.
Cases treated with Antitoxin	44,631	14·6
Cases not so treated	6,507	34·1

Rosenthal (*Medical Press and Circular*, 1900, *II.*, *p.* 293) collected the records of 132,548 cases of diphtheria treated with serum during the years 1894-9, and compared them with 183.256 collected from similar sources before the introduction of serum treatment. The results were as follows:—132,256 cases before serum treatment, mortality 38.4 per cent.; 132,548 cases treated with serum, mortality 14.6 per cent.

11712. Where did Roux collect those statistics?—From Europe and America. That is simply collecting together all available statistics from various countries.

11713. You have some general conclusions which you draw from those statistics?—In drawing conclusions from statistical data of this kind it is obvious that other factors may have to be examined and taken into account as well as serum or no serum. The incidence of a disease like diphtheria is not uniform. It occurs in waves. In certain years it is more prevalent than in others, and no doubt the severity of the disease also varies somewhat in different periods. Another factor which will undoubtedly have modified the case mortality of diphtheria is the adoption of a more accurate method of diagnosing the disease by bacteriological examination. This will most certainly have led to the wider recognition of the disease in mild and atypical cases, and therefore to the inclusion in the statistical data of a number of less severe cases of the disease. The influence of this factor in diminishing the case mortality cannot be directly measured. The universal decline in case mortality coincident

with the employment of a remedy based on rational lines, and capable of being experimentally demonstrated to certainly prevent infection or cure the disease in animals, is, however, highly significant. Moreover, in the early experience in Paris and in that in Russian provinces, quoted above, the mortality of treated and untreated cases at the same time and under similar conditions can be compared. The result is just the same, viz., a case mortality of less than half amongst cases treated with serum.

11714. Then you give particulars as to the mortality from diphtheria per 100,000 of the population living, in relation to the employment of antitoxin?—The employment of a remedy of any value will be a factor in diminishing the death-rate of a disease per 100,000 of the population living. The influence of this factor will be proportionate to the value of the remedy and to the extent to which it is employed. Other factors, however, which must be taken into account, are the prevalence of the disease, and any variation in the severity of its type. As I have already pointed out, the prevalence of diphtheria shows considerable variation from year to year. Groups of bad diphtheria years have occurred, followed by groups of years in which the prevalence of the disease has been less. It will be obvious that if the prevalence in proportion to the total population were doubled and the type of the disease remained the same, the mortality per 100,000 would also be doubled. Again, supposing that a remedy adequately administered halved the case mortality and other factors remained stationary, the mortality per 100,000 would only be halved on condition that the remedy were administered in sufficient amount in every case. If both factors were varying at the same time the result due to the one might be masked by the other. For this reason it is impossible to draw conclusions regarding the value of anti-toxin from general mortality figures alone. I think in previous evidence a question was asked about Hull, as regards the greatly increased mortality from diphtheria in Hull during the last few years, notwithstanding the introduction of the antitoxin. I have the figures for those Hull cases, and they show that the increased mortality is due to increased prevalence. The case mortality for the whole of the cases notified, according to the returns afforded me by the Medical Officer of Health for Hull, remains substantially the same or slightly lower during the last few years than what it was before the antitoxin period. There is, however, a substantial improvement in the mortality of cases treated in hospital where antitoxin was used to a large extent.

11715. (*Sir Mackenzie Chalmers.*) The case mortality of persons treated?—Yes.

11716. (*Dr. Wilson.*) The death-rate from the disease per 1,000 of the population has gone up?—The death-rate has gone up. But then they have had an increased number of cases. And I would like to insist that the antitoxin does not prevent the spread of the disease.

11717. It is used as a prophylactic?—It merely cures the patient.

11718. (*Chairman.*) The individual patient?—Yes.

11719. (*Dr. Wilson.*) But it does cure them all, if so many die?—It does not cure them all, but they do not all get it in sufficient amount.

11720. (*Sir Mackenzie Chalmers.*) A great many are not treated?—No, the average amount the cases must have had in Hull is an extremely small amount, and can be estimated, because they supplied antitoxin free of cost to the profession for their cases, and the amount employed was only sufficient, if equally distributed over those cases, to supply—I am speaking roughly—somewhere between 2,000 and 3,000 units per case. That is found inadequate for treating diphtheria, by the experience of the Metropolitan Asylums Board, who give 20,000 units per case.

11721. (*Dr. Wilson.*) But in early days was not even 2,000 units considered to be a large dose?—Yes. Of recent years the dose of anti-toxin which has been given has steadily risen, and with the increase in dose that has been given the case mortality has come down, as shown in all the figures everywhere.

11722. (*Colonel Lockwood.*) You say that 20,000 units are given now generally?—By the Metropolitan Asylums Board; that is their average.

11723. (*Dr. Wilson.*) For slight and severe cases?—At once, in every case directly it comes in within the first 48 hours.

11724. (*Sir Mackenzie Chalmers.*) Even if it is of several days duration?—Yes, unless it is moribund they always give anti-toxin at the Metropolitan Asylums Board hospitals.

11725. (*Chairman.*) Your original observation was tending to point out the unreliability, to a certain extent, of statistics?—Of the general mortality statistics. The case mortality statistics are perfectly reliable.

11726. (*Sir William Church.*) You did not mean the Commission to infer that they only used anti-toxin in doses of 2,000 units at Hull, but that the total supply of anti-toxin to Hull would only afford 2,000 units instead of 20,000?—Yes. Of course that is the most I can say.

11727. (*Sir John McFadyean.*) Which may mean that those who received adequate doses were only 10 per cent. of those treated at all?—Possibly. I can put those figures in evidence if you like to have them.

11728. (*Chairman.*) Which figures?—The Hull figures. It did not seem to me that Mr. Power was able to give you the answer to the question you asked him. That led me to communicate with the Medical Officer of Health for Hull.

11729. Perhaps you will furnish those figures, and add them to your evidence?—I will.

DIPHTHERIA.

City and County of Kingston-upon-Hull.

Average Case Mortality before antitoxin used -	16·2	22·8
" after " " -	12·4	13·7

Use of Serum commenced in November, 1901.

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

10 July 1907.

11730. You go on to distinguish between diphtheria and the laryngeal cases which, you say, are in the nature of diphtheria. Will you tell the Commission what is the effect of the serum treatment upon the mortality of laryngeal cases?—In a certain proportion of cases the local inflammation of diphtheria, which commonly commences in the throat or nose, extends to the larynx and trachea. This extension increases the gravity of the case, both owing to the larger surface involved, and to the frequent interference with the entrance of air through the narrow orifice in the larynx. To prevent suffocation laryngeal cases commonly require tracheotomy or intubation. The mortality of laryngeal cases has always been much higher than the mortality of those in which the local manifestation of the disease was confined to the nose or throat. In testing the effect of antitoxic treatment upon laryngeal diphtheria there is therefore no question of the inclusion of an unusual proportion of mild cases, so that the mortality of laryngeal cases before or after the introduction of the treatment may safely be compared, and any improvement in the death rate placed to the credit of the antitoxin. Statistics of cases of diphtheria requiring tracheotomy or intubation have, in recent years, been carefully kept by most hospitals. In 8,927 cases collected by Goodall ("British Medical Journal," 1899, volume i., page 197), from hospital records in different countries before 1894, the mortality was 71.6 per cent. With the introduction of antitoxin there was a marked fall in the mortality of cases of diphtheria requiring tracheotomy. In a series of 2,374 cases collected by the same author from similar sources, but in which antitoxin was employed, the mortality was 36.6, or approximately one-half. The same order of improvement occurred in all the principal hospitals of Europe and America in which antitoxin was administered. With the object of coming to a conclusion regarding the curative value of diphtheria antitoxin, the German Health Office (Arbeiten aus dem Kaiserlichen Gesundheitsamte, 1897, 254) obtained returns of diphtheria cases from all the hospitals in the Empire from April, 1895, to March, 1898. Amongst these were 2,041 cases in children up to five years of age, in which tracheotomy had to be resorted to. Of these 778 died; a mortality of 33.6 per cent. The German health authorities compare this mortality with that of tracheotomy cases in children's hospitals in Germany, previous to the introduction of antitoxin, which, according to the statistics of Baginsky, Hirsch, Herz, Gläser, and Feer, varied from 58.4 to 86 per cent., depending upon the age of the children.

11731. Are these cases in the report of the German Health Office cases in which antitoxin had been used?—In the first series of cases antitoxin was used with a mortality of 33 per cent.

11732. When you say returns of diphtheria cases from all the hospitals, does that imply that they were diphtheria cases which had been treated in all cases with antitoxin?—Yes, the treatment was general in hospitals in Germany within those years.

11733. Then you give some results obtained by the antitoxin treatment in tables, showing the influence of early or late administration of antitoxin upon the case mortality from diphtheria?—Data regarding this question have been collected by numerous authorities and the total figures amount to upwards of 20,000 cases.

The Results obtained by Antitoxin Treatment, according to the period after the onset of the disease at which the injection is given (*Dieudonné Schutzimpfung u. Serumtherapie*, 1900.)

Eight thousand and three cases of bacterially-verified Diphtheria treated with Antitoxin by the Chicago Health Department between 1895 and 1905. (Biennial Report of Department of Health, Chicago, 1904-5, p. 137.)

Day of Disease	1st.	2nd.	3rd.	4th.	Later.
Number of Cases	608	2,063	2,802	1,496	1,034
Cases of Mortality per cent.	·32	1·66	3·64	11·03	21·08

From the above records it is clear that those cases in which antitoxin was administered on the first day have the lowest mortality, and that the death rate rapidly rises as the period between the onset of the disease and administration of the serum increases. This is exactly what happens in animal experiments. If antitoxin be administered to an animal on the same day as it is injected with a fatal dose of diphtheria bacilli, 100 per cent. can be saved. If on the day after a large percentage of treated animals recover. If on the third day only a small percentage; and after the third day antitoxin is unable to prevent death—that is in animals. In other words, antitoxin is a remedy definitely known to be proportionately more effective the earlier it is administered, and the experience quoted above, derived from a wide source, shows that this is the case when the serum is administered to children, just as was to be expected from animal experiments If antitoxin were a remedy of no value, whether it were administered on the first or fifth day of the disease would be immaterial.

11734. What is the dangerous date in diphtheria? At what days would you expect in a bad case, in an average case, say, a crisis?—On which day would death take place, do you mean?

11735. Yes?—They may die any time after the second or third day, in very bad cases.

11736. What is the effect of antitoxin upon the incidence of diphtheria paralysis?—The incidence of paralysis in cases of diphtheria treated in the hospitals of the Metropolitan Asylums Board has risen about 6 per cent. since antitoxin was introduced. This was to be expected, from experimental knowledge of the action of diphtheria poison and of the influence of antitoxin upon an animal which had been either injected with this toxin or inoculated with the bacilli. If antitoxin be given to an animal in sufficient quantity and sufficiently early in the disease, both the acute symptoms and the paralysis, which may occur about three weeks later, are prevented. On the other hand, when the dose of antitoxin is not quite adequate the acute symptoms may be prevented, but the late paralysis may still supervene. Reasoning from analogy, it would seem probable that the increased percentage of paralysis is due to a considerable number of cases which would otherwise have died of acute poisoning, being saved by late or insufficient administration of antitoxin. This supposition is supported by the facts adduced in the following table, indicating the proportion of paralysis which occurred amongst patients treated with antitoxin upon the first, second, third, fourth, and fifth days of the disease respectively.

Day of Disease upon which Antitoxin was first injected.	Total number of Cases.	Total number of cases of Paralysis.	Percentage incidence of Paralysis.	Number of severe cases of Paralysis not fatal.	Number of fatal cases of Paralysis.
First	69	4	5·7	0	0
Second	277	28	10·1	1	0
Third	340	53	15·5	5	3
Fourth	323	61	18·8	8	7
Fifth, and later	571	147	25·7	28	8
Total	1,580	293	18·5	42	18

11737. Then you give a summary of the facts?—The foregoing facts relating to the influence of antitoxin in the treatment of diphtheria may be briefly summarised as follows:—(1) Diphtheria can be cured with certainty in animals by treatment with antitoxin. (2) The earlier the treatment is applied to an animal the less the quantity required and more certain the cure, and if the administration of antitoxin is delayed beyond a certain time the treatment is ineffectual. Those are the facts as regards animals. (3) A reduction of case mortality of diphtheria to one-third or one-half occurred universally coincidently with the introduction of the antitoxin treatment. (4) In many places a corresponding diminution in mortality in proportion to population occurred; but in some countries this has been masked by a simultaneous increase in the prevalence of the disease. (5) A similar fall in case mortality amongst the severest forms of diphtheria, viz., those necessitating tracheotomy, has been universally experienced, so that the apparent beneficial results of serum treatment cannot be explained by the supposition that after 1895 a milder form of the disease was suddenly and universally encountered. The beneficial results of serum treatment are greater, the earlier in the course of the disease the treatment is applied, and after the fourth or fifth day the administration of anti-toxin produces little or no influence upon the case mortality. This is absolutely in accord with what was known of antitoxin from the results of experiments upon animals.

11738. Do you attribute the discovery of the serum and the efficiency of it and the way to use it, to experiments on animals?—Entirely.

11739. Then you have something to say as regards the prophylactic action of diphtheria antitoxin?—The use of antitoxin as a remedial agent does not materially diminish the spread of the disease, for an individual remains infective for weeks, or sometimes months after convalescence. With the object of stamping out epidemics of diphtheria, it can, however, be employed as a prophylactic measure with great advantage. As previously mentioned the shorter the interval between the inoculation of an animal with diphtheria bacilli or diphtheria toxin and the treatment with anti-toxin the less is required to prevent a fatal issue. When the antitoxin is administered before the bacilli or toxin the amount of the former required is still further diminished, and a complete protection can be obtained. This prophylactic use of serum can be advantageously employed to prevent the spread of the disease in schools and institutions, and so readily suppress outbreaks of the disease. Hitherto, in England, diphtheria antitoxin has not been much used as a prophylactic, though in certain outbreaks, such as those at Cambridge and Chesterton, it was employed with considerable success (*Cobbett, J. of Hygiene, Vol. I.*). In France, Germany, and America, however, it is commonly employed with this object, and very valuable results have been obtained in this direction. The following experience occurred in Heubner's clinic (*Lohr. Jahrbuch f. Kinderheil kunde Bd.* 43, *Ht* 1, *and Slawyk, Die Therapie der Gegenwart*, 1899). From 1895 onwards prophylactic injections were given every three weeks to all the patients, and the outbreaks of diphtheria which had formerly regularly occurred in the wards, came to an end. In October, 1897, this precautionary measure was stopped in a wing not used for infectious cases, and in November cases of house infection broke out in this department. A general prophylactic inoculation was again employed, and the occurrence of cases completely ceased. Netter (Bull. de l'acad de med. Paris, March, 1902), principal health officer for Paris, reports the following instance:—In the presence of an epidemic of diphtheria in Paris among 491 children exposed to infection who did not receive protective injections, 88 contracted the disease; while

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

10 July 1907.

of 502 children, who had been similarly exposed and were given protective injections, only 13 became infected. Of these 7 developed the disease within 24 hours, and 6 more than a month after the injections. Since the immunity does not begin for 24 hours and passes off in approximately three weeks, these figures strongly support the prophylactic value of the remedy. The preventative action of antitoxin is extensively taken advantage of in America. Biggs (New York Med. Journ., 1900, lxxi., p. 234) states that out of 3,109 children to whom antitoxin was administered only 9 acquired diphtheria; and Park (Journ. Amer. Med. Assoc., 1900, i., p. 902) records 6,506 cases of immunisation, among which 28 developed the disease within 24 hours, that is before the protection was effective, while only 274 were attacked after this limit of time.

11740. You now come to tetanus antitoxin as a curative agent?—It is possible to obtain tetanus antitoxin of extraordinary preventive power, as tested experimentally by injecting the serum previously to the toxin. The experimental results are satisfactory when the two are mixed together at the time of injection; but as a curative agent, in practice its value is far less than that of the corresponding antitoxin for diphtheria, because the disease is usually only discovered after serious lesions of the nervous system have already been produced, upon which, unfortunately, the antitoxin can exert little influence. The injection of antitoxin can neutralise toxin circulating in the blood, and combine with any toxin which may be formed after its injection, but it cannot restore damage done to the nervous elements, although it can prevent nervous elements from being attacked. Koehler (*Münchner Med* 12. *Wochschr.*, 1893), dealing with the statistics of ninety-six cases treated by antitoxin, found the death-rate to be 30.4 per cent., which is certainly much below the normal death-rate, viz., 86 per cent. On the other hand, Steuer (*Centralbl. f. d. Grenzgebiete d. Chir. u. Med.*, 1900), from his statistics, could demonstrate no improvement over cases treated without antitoxin.

11741. (*Sir William Collins.*) One observer showed a reduction of 50 per cent., and the other showed none?—That is so.

11742. (*Chairman.*) Have you any suggestion as to how that could arise?—Different dosage possibly. Unfortunately the damage is done before you know that the person has got tetanus.

11743. You mean it has got too late?—Yes.

11744. Then it may be from that or it may be from the proper dose not being administered?—Yes; it is not very hopeful under any circumstances.

11745. What is not very hopeful?—The antitoxin treatment of a case of tetanus which has developed.

11746. What time after the injury would you say was the time you expect it to develop?—It may be anything from a few days to months; it is not of immediate onset. The most acute cases develop most rapidly.

11747. Do you mean that if a person has a bad fall and scrapes all the skin off his hand in a dirty place it would take weeks to develop?—Yes. I am not sure of the shortest time that has ever been recorded, but certainly it is unusual for the symptoms to occur in less than a week.

11748. (*Sir John McFadyean.*) The usual period after inoculation is about a week, is it not, in animals?—Yes.

11749. (*Chairman.*) Then what have you to tell us with regard to the prophylactic action of the tetanus antitoxin?—Whatever doubts may be entertained of the value of this antitoxin as a curative agent—as a prophylactic its power is fully established. In veterinary practice, where it has been used under test conditions, it has proved infallible. The bacillus of tetanus is common in dung, and hence on the skin of horses. A considerable mortality from tetanus occurs in veterinary surgery, owing to the entrance of the bacillus into wounds, especially in castrations, which from the situation of the wound are particularly liable to be contaminated. Nocard has collected the results of the experience of prophylactic injections gained by 63 veterinary surgeons during a period of 22 months.

11750. Does that mean that the tetanus bacillus may be swallowed with impunity? You say it is common in dung. I suppose it has been swallowed by the horse?—Yes, swallowed in the hay and food, and it usually lives quite comfortably in its intestine.

11751. And it is not injurious in passing through the human body?—No, not unless it gets in through any abrasion. Certain cases apparently arise in that way from abrasions in the alimentary canal of horses. 2,700 cases, both operative and traumatic, were selected for preventive inoculation from those in which by experience they knew that tetanus was most likely to occur. Not one of these 2,700 animals contracted tetanus; whereas, in the practice of the same veterinary surgeons, during the same period, but not so treated, 259 cases of tetanus occurred (*Nocard, Comptes rendus du Congrès de Moscou*, 1897, *t. vi.*, *p.* 244).

11752. (*Sir William Collins.*) Perhaps you will add the reference in cases where you do not give the authority. In some cases you do, and in some you do not?—I will, where I can do so. I can nearly always give the reference to the original, but sometimes I have to depend upon the collected statistics. The originals would be very troublesome.

11753. Then in that case perhaps you will give the reference to the collected?—Yes.

11754. (*Sir Mackenzie Chalmers.*) And the collectors?—Yes. In case of severe wounds in man, such as compound fractures, where there has been much soiling of the wound, and especially if earth has found its way into the depths of the wound, a prophylactic injection of tetanus antitoxin is advantageously employed. Herhold ("Deutsch Med. Woch," 1901, page 479), who was surgeon to the German contingent on the expedition to Pekin, at first lost several patients by tetanus. Afterwards he used prophylactic injections in all cases of crushed wounds, contaminated with dirt, and no more cases of the disease occurred.

11755. (*Chairman.*) Then you mention dysentery antitoxin. I do not think we have heard of dysentery antitoxin before?—Epidemic dysentery is an infectious disease, which is more particularly liable to assume serious proportions when individuals are crowded together in gaols, asylums, or camps. It is in war especially that dysentery becomes a formidable disease, both on account of the high death rate and of the number of men thrown out of action, often for prolonged periods. Knaak (Die Krankheiten, in Kriege, Leipzig, 1900) states that in the American War of Secession, 1861-1864, there occurred 259,071 cases of acute dysentery, with 5,576 deaths; and of chronic dysentery 28,451 cases, with 3,855 deaths. In the Franco-Prussian War of 1870-1871 there were 38,652 cases (49 per thousand) and of these 2,380 died—62 per cent. of those affected. In addition there were 223 cases among officers, etc., with 25 deaths. The bacillus of bacterial dysentery was first isolated by Shiga, in Japan (centralb f. Bakt, 1898). Kruse found the same bacillus in an outbreak of dysentery in South Germany (Deutsch Med. Woch, 1900-1901), and Flexner in Manilla (Centralb f. Bakt, 1901). The bacillus is pathogenic for the guinea-pig and rabbit. In these animals the bacillus itself, or the poison obtained by growing it in broth, produces dysenteric diarrhœa, severe nervous symptoms, paralysis, and death within a few hours or days, according to dose. In the intestines of these animals morbid changes, similar to those occurring in man, have been observed.

11756. Then as to serum therapy in this connection?—Shiga (*Deutsch Med. Wochschr.*, 1901) first immunised horses against the dysentery bacillus, and employed the serum as a therapeutic agent in man. Kruse (*Deutsch Med. Wochschr.*, 1903, *p.* 49) obtained a similar serum by using the bacillus isolated by him in Germany, and Rosenthal (*Centralbl. f. Bakt*, 1904, *p.* 463), Todd (*Brit. Med. Journ.*, 1903, *J. of Hygiene*, 1904, *p.* 480), and others have added to the knowledge of the subject.

11757. What are the properties of the serum?—Anti-dysentery serum possesses preventive and curative properties when employed on animals, inoculated either with the living bacillus or its toxins. All the pathogenic effects referred to as occurring in experimental animals can be prevented or cured.

11758. Have any results been obtained in the case of man?—No extensive data as to the value of anti-dysentery serum as a therapeutic agent in man are as yet available, but so far as it has been used the results recorded have been of a very promising character. Shiga (*loc. cit. supra*) used his serum on 298

cases, and obtained a reduction in the death rate to one-third of the rate in cases not treated by serum, the death rate in cases receiving only serum treatment was 10.8 per cent., and in 2,599 cases, treated by other means, 35.4 per cent. Kruse treated 100 cases with good results. Of 19 patients under 10 years one died, which is equal to a death rate of 5 per cent., the usual mortality in cases of this age being from 13 per cent. to 20 per cent. The injection of the serum was followed by a rapid reduction in the number of stools, and by the improvement in the general condition. Similar results were obtained at Moscow by Rosenthal (Centralb f. Bakt, 1904), in 157 cases treated with serum. The death rate was 4.5 per cent., compared with 10.11 per cent. in other hospitals during the same epidemic. When the serum was used in the first three days recovery took place in one or two days. Rosenthal's serum was employed in the Russo-Japanese War. Koreutchewsky (Bull. l' Inst. Pasteur, 1905) treated 70 cases, and found the treatment very efficacious. The painful symptoms were controlled as by a narcotic. Barikan (quoted by Vaillard and Dopter) treated 59 cases in Manchuria, with one death. Vaillard and Dopler (*Ann. l'Inst. Pasteur*, 1906) treated 96 cases, all of a severe type, with one death.

Cases of moderate severity, 50; deaths, 0.
Severe cases, 18; deaths 0.
Grave cases, 24; deaths, 0.
Extremely grave, 4; deaths, 1.

These authors found, like other observers, that after the use of the serum there occurred a diminution in the frequency of the stools. The painful symptoms, such as spasms and colic, were ameliorated.

11759. I gather that this antitoxin has not been tested nearly as much as the previous ones for diphtheria and tetanus?—That is so.

11760. I understand that you consider the antitoxin tetanus is a perfect remedy if applied in the right dose at the right time?—Perhaps I might explain a little more fully. If you injected a person with tetanus, it is my belief that in man, as is the case in animals, if you gave him a dose of tetanus serum the next day he would certainly not get tetanus.

11761. That is what I meant. You look upon it as a certain remedy if applied very promptly?—Yes, if it is applied as a precaution. You cannot tell that a person is going to have tetanus every time he gets a wound and soils his fingers. In most cases he will not.

11762. I quite understand the difficulty. It may not be a case of negligence in not giving it to him. But at the same time, if it were given him you say it would save him?—Certainly, I think so.

11763. With regard to diphtheria, do you say the same thing?—My own belief is that if a child could be treated with the diphtheria antitoxin in an adequate amount and sufficiently early in the disease the mortality would be nil. The moment you knew that the child had diphtheria, if you could treat him with antitoxin the mortality would be nil. That opinion has also been stated by the Medical Officer of Health of Chicago from his experience of the disease in that city, where they distribute diphtheria antitoxin free to every doctor, provided that he afterwards fills up a form to say that his patient cannot afford to purchase it.

11764. As to dysentery, you cannot speak with the same confidence, I understand—No, but from the experiments on animals I regard the dysentery antitoxin as for practical purposes coming after the diphtheria antitoxin. In practical value it will, I think, make a good second to the diphtheria antitoxin.

11765. And you have warning that there is dysentery much more promptly than you have in the seeds of tetanus?—Yes, before you know that a person has got tetanus the damage is unfortunately done.

11766. (*Sir William Collins.*) Did you say that the mortality in Chicago had been reduced to nil?—No, I said that the opinion which I have just expressed that if you could take a child with diphtheria sufficiently early and adequately treat it with antitoxin, the mortality would be nil, coincides with that of the Medical Officer of Health for Chicago from his experience in that city.

11767. Can you tell us how far that result had been achieved in Chicago?—I can give you the statistics of the general mortality in Chicago. Unfortunately, I have not available the case mortality statistics in Chicago.*

11768. (*Sir Mackenzie Chalmers.*) May I put it in this way to see if I understand it: According to your belief, if every contact, if every person who comes in contact, and is therefore liable to infection, received a proper dose, you would have no development of diphtheria in contacts?—That is also my belief, but that it not what I was expressing before.

11769. It comes to the same thing, does it not?—Quite so.

11770. (*Sir John McFadyean.*) What you mean really is, that if, at the moment the first lesions are visible in the throat, the child got 20,000 units, there would be no mortality from diphtheria?—That is so.

11771. (*Dr. Wilson.*) In spite of the severity of the type?—Yes.

11772. (*Sir Mackenzie Chalmers.*) What is the incubation period of diphtheria?—About ten days.

11773. (*Sir John McFadyean.*) I suppose that has been experimentally proved to be not true for the tetanus antitoxin?—Yes.

11774. You quote Nocard's observations here that he collected, but I do not know whether you are acquainted with another set of experiments in which he infected animals deliberately, and then gave them anti-tetanus serum at intervals afterwards, and found practically that no recoveries took place when the first dose of the serum was given on the onset of symptoms?—Yes, I am familiar with those observations.

11775. Is it the fact that all those who were treated before the onset of the symptoms recovered?—I cannot say the whole of them. So far as regards some of those that were treated just before the onset of symptoms, there was I believe a small mortality amongst them.

11776. (*Dr. Gaskell.*) What do you mean by being treated on the first day. What is the first day of diphtheria?—The first day is the first day that the disease is recognised.

11777. (*Sir Mackenzie Chalmers.*) By the appearance of the false membrane?—By a combination. I imagine that in most of these cases the first day in the Metropolitan Asylums Board Reports refers to the first day that the disease is recognised by the presence of the bacilli in the throat and by some symptoms of illness, such as sore throat or slight malaise.

11778. (*Sir William Collins.*) Does not the statement which you have just made to the Commission amount to this: That in your opinion every death from diphtheria is preventible?—Only under ideal circumstances.

11779. (*Dr. Wilson.*) And by this serum?—By the serum.

11780. (*Sir Mackenzie Chalmers.*) If every contact was treated you would have no development of the disease in any one?—I believe not; not if it was adequately treated.

11781. (*Sir John McFadyean.*) I suppose part of the ideal circumstances would be at least a daily inspection of the throat of every young child. I mean in the family?—Yes.

11782. (*Dr. Wilson.*) But you admit that in a great many healthy persons you find the bacillus?—Yes, occasionally.

11783. How about those?—I do not quite understand your question.

11784. You have admitted that in the throats of apparently healthy persons (they may be in a diphtheria house or not) you do find the bacillus?—Yes.

11785. Would you inject these?—If they are not ill?

11786. If they are not ill?—Certainly—if you want to stop the outbreak.

11787. What about the patients who have had the disease in whose throats the bacillus may be detected

* *The data asked for were already given in answer to Q. 11733 in the table showing the mortality from diphtheria in 8,000 cases treated in Chicago on different dates of the disease, where it may be seen that of 608 cases treated on the first day of the disease the mortality was ·32 per cent.—C. J. M.*

Mr. C. J. Martin, M.B., D.Sc F.R.S.

10 July 1907.

months afterwards as you say?—It is no good injecting them.

11788. But you hold that they are in an infectious state?—They are in an infective state; they can infect other people.

11789. And can be kept away from work?—Unfortunately they have to be.

11790. No, I think you would put a stop to the employment of a great many men if that could be done. I think you must go by the physical symptoms and not the bacteriological. If you go in for the bacteriological test out and out you would have to confuse a great many people?—That is so. If you test convalescents and contacts bacteriologically you will find a great many people in apparent health who are carrying about the diphtheria bacilli. That is how the disease is spread.

11791. That is an assumption?—It is my opinion, of course.

11792. (*Chairman.*) We will go on to the next question. You were going on to speak about vaccines against plague and typhoid fever. What have you to say with regard to them?—The discovery by Pasteur, that animals could be protected against chicken cholera and splenic fever by inoculation with attenuated cultures of the organisms which cause the diseases, and the practical value of this process in counteracting the ravages of these diseases has already been mentioned. The inoculation of mankind with living attenuated cultures, according to the Pasteurian method has been made use of in the case of cholera, but the apprehension that at any moment the virulence of attenuated organisms might possibly become enhanced has prevented the general adoption of this method of protective inoculation in the case of human beings. In 1888 Gamaleia (*Ann. l'Inst. Pasteur*, 1888, 1889) found that guinea pigs and pigeons could be protected against infection with an organism (vibrio metschnikovi) by the previous inoculation of killed cultures of this vibrio. Gamaleia had found this microbe to be responsible for a disease of poultry in Odessa. It also kills guinea pigs and pigeons. This was an important discovery, as it showed that to produce protection it was not essential to infect with the living microbe, but that some degree of immunity could be induced by the inoculation of the chemical products contained in the substance of the dead organisms. Subsequently the principle discovered by Gamaleia was by experiments on animals, extended to other diseases, *e.g.*, cholera, typhoid (Brieger and Wasserman, *Zeitschr. f. Hyg. Bd.* 12, *and Deutche Med. Wch.*, 1892; Pfeiffer, *Zeitschr. f. Hygiene, Bd.* 21, 1896) and plague (Yersin). In 1895 plague broke out in Bombay and spread throughout the city, and extended to neighbouring places. The general sanitary measures employed proved powerless to prevent the spread of the disease. Haffkine therefore turned his attention to the problem of preventive inoculation against plague in the hope of arriving at a useful method which could be applied upon a large scale to man. After numerous experiments with cultures of the plague bacillus which had been killed by a variety of means, Haffkine decided upon a broth culture of the organism sterilised by heating to 65 deg. C. Having tested the vaccine by innoculating first himself and then the personnel of his laboratory, the first extensive trial of the efficacy of this vaccine was made in January, 1897, upon the inmates of the Byculla Jail, where plague had broken out (*Statistics of inoculations with Haffkine's antiplague vaccine*, 1897-1900. *Bannerman—Gov. Central Press Bombay*, 1900). The submission to inoculation was voluntary. The jail contained 337 adults of both sexes, who were not obviously infected with plague. 154 offered themselves for inoculation. Three of these were, however, in the incubation stage of plague, for they developed plague the same evening. For the purpose of arrivng at an estimate of the value of the preventive inoculation these persons in the incubating stage of the disease must be eliminated from the calculation, as also many cases amongst the uninoculated, who also developed plague upon the day the injections were made, leaving 177 uninoculated and 151 inoculated. The result of this experiment was as follows:—

	Number of Persons.	Cases of Plague.	Deaths.
Uninoculated -	177	12	6
Inoculated - -	151	2	0

In December, 1897, an outbreak of plague occurred in another jail in Bombay (Umkardi) thus affording a further opportunity of testing the efficacy of Haffkine's vaccine, under conditions as favourable for the formation of a judgment as it is possible to obtain in connection with human diseases.

	Number of Persons.	Cases of Plague.	Deaths.
Uninoculated -	127	10	6
Inoculated - -	147	3	0

Another opportunity for testing the efficiency of Haffkine's vaccine occurred in the village of Undhera. The whole population of this village was assembled in family groups, and the intention was to inoculate every alternate person. The total number of inoculated persons was 513, and uninoculated 437. The larger number of inoculated was owing to the insistence of some individuals to participate in the possible advantage of inoculation. The epidemic lasted 42 days, and the result was as follows:—

	Number of Persons.	Deaths.
Uninoculated - - - - -	437	26
Inoculated - - - - -	513	3

On the strength of the favourable results of the above experiments Haffkine's method of inoculation was officially adopted by the Government of India, and the arrangements made for the manufacture of vaccine on a large scale. During the plague season 1902-3, 505,398 persons were inoculated in the Punjab alone. (Report on plague and inoculation in the Punjab from October 1st, 1902, to September 30th, 1903.) The official report gives details concerning the villages of 12 districts in which the proportion of inoculated persons was greatest. The number of inoculated in these 12 districts was 224,428, and the uninoculated, as estimated from the total population, 639,600. The number of cases and deaths from plague were as follows:—

	Number of Persons.	Cases.	Deaths.	Cases per cent.	Case Mortality per cent.
Inoculated - - - - - -	224,428	3,393	814	1·5	23·9
Uninoculated - - - - -	639,600	49,430	29,733	7·7	60·1

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

10 July 1907.

In the case of the district of Amritsar (Browning-Smith. Report on plague and inoculations in the Amritsar district, 1902-3, "Indian Medical Gazette," 1904) the inoculations and subsequent observations were all made by one individul, and as these show evidence of having been conducted with particular care, they are worth quoting.

	Number of Persons.	Cases.	Deaths.	Cases per cent.	Case Mortality per cent.
Inoculated	30,839	572	150	1·21	26·2
Uninoculated	130,927	11,233	7,883	8·58	70·2

The value of inoculation against plague is undoubted. According to the less favourable of the above figures the chances of a subsequent infection are reduced to one-fifth by this means, and the chances of recovery are two and a half times as great as in the case of the uninoculated. In other words, the mortality has been reduced to one-twelfth by inoculation.

11793. You now come to anti-typhoid vaccination?—Typhoid fever is a disease to which our soldiers are particularly liable, especially those stationed in warm climates. In India the loss to the British Army from deaths alone amounts to half a battalion a year, apart from the pecuniary loss to the State through sickness and invaliding. In war the loss is much more serious; more men being often placed *hors de combat* through this cause than by the bullets of the enemy. Consequently any practicable means whereby the incidence of typhoid fever amongst troops can be reduced is of the utmost importance to the British Army. The subcutaneous injection of minute quantities of killed typhoid bacilli in animals—guinea-pigs or rabbits—protects them against a subsequent fatal dose of the living bacilli. The immunity is greater when three or four such injections, separated by an interval of 10 to 14 days, are made, than with a single injection. A method of preparing a vaccine against typhoid fever was devised by Wright and Semple in 1896. They satisfied themselves of the innocuousness of their vaccine by experiments—first upon themselves, and subsequently upon their friends. The first trial of protective inoculation against typhoid fever was made in October, 1897, at the Kent County Asylum, where there was an outbreak of the disease. (The figures quoted in par. 11793 to 11799 are taken from "The Practitioner," March, 1904.) The treatment was offered to the nurses and attendants of the Asylum, and 84 out of 200 accepted the offer. Four cases of typhoid occurred in the uninoculated, but none among the inoculated. The figures were inadequate to enable one to form any opinion regarding the value of inoculation, but were sufficient to show the innocence of the method, and to justify more extended trials. The first anti-typhoid inoculations on a large scale were made amongst British troops in India (Bangalore, Rawul Pindi, Lucknow), when the Plague Commission, of which Professor Wright was a member, was in India, November, 1898, to March, 1899. These inoculations were voluntary, at private cost, and without official sanction; though the original proposal for them, in 1897, had come from the Indian Government. The results of these early Indian inoculations were as follows:—

Number under Observation.	Cases.	Deaths.	Percentage of Cases.	Percentage of Deaths.
Inoculated 2,835	27	5	0·95	0·2
Uninoculated 8,460	213	23	2·5	0·34

On 25th May, 1899, the Indian Government made application to the Secretary of State for India that the inoculations should be sanctioned, and should be made at the public cost. The application contained the following:—"The anti-typhoid inoculations have been, we believe, on a sufficiently large scale to show the actual value of the treatment, while the results appear to afford satisfactory proof that the inoculations, when properly carried out, afford an immunity equal to or greater than that obtained by a person who has undergone an attack of the disease; further, the operation is one which does not cause any risk to health."

11794. (*Sir William Collins.*) You do not give the case mortality in those Indian cases. I see in the inoculated there were 27 cases with 5 deaths, that is about 1 in 5. Then in the uninoculated 213 cases and 23 deaths; that is about 1 in 9, is it not?—Yes; I have not put the case mortality down.

11795. You have given it in so many figures, that I thought you might have added it there?—I have not done the arithmetic, you mean. It shall be done. Sanction for anti-typhoid vaccination having been given, a number of men from several regiments were inoculated. The regiment in which the largest number of men were inoculated was the 15th Hussars, which remained in India. The incidence of typhoid in this regiment from the 22nd October, 1899, to 22nd October, 1900, is given below:—

	Strength.	Inoculated.	Cases.	Deaths.	Not Inoculated.	Cases.	Deaths.
Officers	22	19	0	0	3	0	0
N.C.O. and men	481	317	2	1	164	11	6
Women	36	24	0	0	12	0	0

From which it is seen that the incidence of typhoid amongst the uninoculated was 5.8 per cent., and amongst the inoculated 0.55 per cent., or less than one-tenth.

11796. Where is the reference to that published? Is it in "The Health of the Army" Annual Reports?—Those statistics were published in the medical papers, "Lancet" or "British Medical Journal," and were collected together in "The Practitioner," March, 1904.

11797. Would they be in some official publications?—I do not know whether they were in an official publication. The Army Medical Department supplied Wright, while typhoid inoculation was going on with the figures, which he published from time to time in the "Lancet," I think.

11798. I do not think they appear in the annual Blue Book, entitled "The Health of the Army," do they?—I do not think so.

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

10 July 1907.

11799. (*Chairman.*) You proceed to give the results of anti-typhoid inoculation amongst British troops during the South African War?—The statistics concerning the campaign in South Africa, which have been collected together by the Army Medical Department, indicate a substantial diminution both of the incidence and deaths from typhoid fever amongst the inoculated. The following instances are taken from these reports:—

GARRISON OF LADYSMITH.

——	Number.	Cases.	Deaths.	Per cent. Incidence.	Case Mortality per cent.
Uninoculated - - - - -	10,529	1,489	329	14·14	22·1
Inoculated - - - - -	1,705	35	8	2·05	20·3

MANCHESTER REGIMENT, WINBURG.

——	Number.	Cases.	Deaths.	Per cent. Incidence.	Case Mortality per cent.
Uninoculated - - - - -	547	23	7	4·2	30·4
Inoculated - - - - -	200	3	0	1·5	0·0

7TH HUSSARS, SOUTH AFRICA.

——	Number.	Cases.	Deaths.	Per cent. Incidence.	Case Mortality per cent.
Uninoculated - - - -	244	20	3	8·2	15·0
Inoculated - - - - -	307	7	0	2·9	0·0

Those are the extracted ones. There are a number of other figures collected. I chose those which seemed to give the clearest idea and were best capable of comparison between inoculated and uninoculated.

11800. (*Sir William Collins.*) Where are they published?—They are all published in "The Lancet."

11801. Is there no official publication of them?—I think not at present.

11802. (*Chairman.*) Is not the Army Medical Department an official body; do they not officially publish it?—I am sure that these figures have not been officially published; because when that Committee of Inquiry into Anti-Typhoid Inoculation was called together, we were supplied with a copy of "The Practitioner," March 1904, in which Wright had collected all these cases, and which were certified to by the statistical officer to the Army Medical Department as being correct. If they had had an official publication containing these figures they would obviously have placed it before us.

11803. At any rate, you have described what the source of them is?—Yes. More recently a carefully conducted test has been carried out under the auspices of the Anti-Typhoid Inoculation Committee, appointed by the Secretary of State for War. (An account of this outbreak was published in the Journal of the R.A.M.C., May, 1907.) In August and September, 1905, a proportion of the 17th Lancers, whose total strength was 490 men and 24 officers and wives, were inoculated with anti-typhoid vaccine. This regiment embarked for India on September 6th, and proceeded to Meerut, where they went into the camp. The number of inoculated was 150, 127 of whom were inoculated on two occasions; 14 days elapsed between the two inoculations. In October, whilst the regiment was still in camp, enteric fever broke out, and 46 cases occurred. Of these 45 were amongst the uninoculated and 1 amongst the inoculated. The men, both inoculated and uninoculated, were all mixed up together in the camp and exposed to the same chances of infection. The value of anti-typhoid inoculation can no longer be regarded as doubtful, and considerable effort is being made by the Commander-in-Chief in India to secure the inoculation of as large a proportion as possible of the British Army in India.

11804. (*Dr. Wilson.*) That is not Wright's antitoxin?—It is essentially the same. The dose is different; it is much smaller. On experience it was found advisable to diminish the dose; it was as effective, and gave rise to less symptoms of soreness.

11805. (*Sir William Collins.*) Has that Committee reported?—No, it has made an interim report only.

11806. (*Chairman.*) Are these statistics taken from the interim report?—These figures of the 17th Lancers have been published in the Royal Army Medical Corps Journal.

11807. (*Sir William Collins.*) Have they been published in any Parliamentary Paper?—I do not think so.

11808. Not the interim report?—What became of the interim report I do not know. It went to the Army Council. Whether they presented it as a Parliamentary Paper, I do not know.

11809. Is the final report ready?—No; the investigation is still going on. This was an attempt to get an experiment that should be carefully controlled; about half the persons were inoculated, and about half uninoculated, and a special medical officer was sent out to watch them and to diagnose every case, so as to make sure that it was really typhoid. We had done that in the previous years, but we cannot ensure that the draft will go to a neighbourhood where there is any typhoid or any opportunities of contracting typhoid; so that, having made preparation for a test of this kind, one is never sure whether there will be any opportunity for its being carried out. In the case of the 17th Lancers they went straight away to Meerut, and encountered an epidemic of typhoid.

11810. (*Sir John McFadyean.*) I should like to ask whether, in view of the clearness of that result, you think it will be a moral proceeding to repeat that—that is to say, for the whole of the men to be sent out to have the advantage to be derived from this vaccination?—The morality question rests with the War Office. Our reference is to obtain information.

11811. (*Dr. Wilson.*) Vaccination is voluntary, of course?—Yes.

11812. Is there any inducement given to the men?—No.

11813. (*Chairman.*) You said as regards this anti-typhoid inoculation that, so far as the experiments go, you think they show very valuable results?—Yes, I think so.

11814. (*Sir William Collins.*) Has any order been issued by the Commander-in-Chief in India with reference to this?—He issued instructions that he would like as many men vaccinated as possible. There has been no order to say that men must be vaccinated. I doubt whether that is in his power, or whether it would be discreet for him to do so, even if he wanted to.

11815. But an order has been issued recently?—I can only tell you that a telegram came home from the Commander-in-Chief, saying that he would wish as many men coming out to India to be inoculated as possible; but that order did not come to the Committee.

11816. That is what you mean by a considerable effort being made by the Commander-in-Chief in India to secure the inoculation of as large a proportion as possible of the British Army in India?—Yes.

11817. (*Chairman.*) Now, you come to the importance of animal experiments in providing a pure food and water supply for the community. Those experiments for that purpose are conducted by various public bodies, are they not?—Yes.

11818. A certain number of public bodies all over the country?—Yes, public bodies are the great vivisectors in this country.

11819. I do not know that that would be accepted exactly as a doctrine by everybody—that they are the great vivisectors, but they are the great persons for making experiments on animals?—Yes.

11820. And you consider, I understand, that these experiments are necessary and of the highest value to the community?—Yes. Bacteriological methods are now largely employed as an aid in securing for the community a pure food and water supply. Animal experiments are necessary in many of these examinations, and many others would be impossible, but for knowledge previously acquired from experiments on animals. These methods are used not only to trace the origin and spread of outbreaks of disease due to contaminated food and water which may occur, but are constantly employed by municipal and other health authorities to test the purity of meat, milk, and water which is supplied to the public. To begin with milk, cheese and butter. In the examination of these products for tubercle bacilli, diphtheria bacilli, the Malta fever coccus, typhoid bacilli and allied organisms, animal experiments are had recourse to. The testing of dairy cattle with tuberculin may also be cited as a method utilised to secure a milk supply free from the infection of tuberculosis. In the case of meat, animal experiments are employed to discover the presence of anthrax bacilli and tubercle bacilli. In tinned meats and sausage poisoning the recognition that outbreaks of food poisoning (so-called ptomaine poisoning) are due to the bacillus enteritidis of Gaertner, and the bacillus botulismus, Ermengen, has been of use in indicating preventible dangers in connection with the consumption of certain foodstuffs, particularly those arising from the utilisation of infected meat for the manufacture of pies and sausages and for canning purposes. This knowledge depends entirely upon animal experiments. Since the causation of these outbreaks of food poisoning was understood sanitary inspectors have been alert to obviate this danger, and suspected carcases or preserved foodstuffs are submitted to bacteriological examination, and, if necessary, condemned. In the case of trichinosis, the relationship of this disease to the presence of the parasite trichina spiralis in pork and hams, and the consequent necessity for the examination of the carcases of pigs for the presence of the parasite was directly due to animal experiment. Water is examined for typhoid, anthrax and cholera bacilli and other organisms indicating pollution, such as bacillus coli communis, the recognition of all of which is either directly due to or based on animal experiments.

11821. Then you state the reasons why the varieties of animals employed in scientific experiments should not be restricted?—The following are, in my opinion, very strong reasons why the variety of animals employed for scientific experiments should not be restricted, and particularly why dogs should not be excluded from use for this purpose. (I.) Diseases peculiar to these animals, such as distemper and epidemic jaundice (piroplasmosis) require investigation both in the interest of possessors of these animals and of dogs themselves. (II.) One case at least is known, and this is a very important one, in which dog and man harbour two stages of the same parasite ecchinoccus or hydatids. This parasite is not responsible for any great amount of damage in Great Britain, but in some pastoral countries, notably Australia and Iceland, the proportion of the rural population which becomes infected with hydatid cysts is very considerable. In Iceland it has been estimated by the chief medical officer that one-seventh of the entire population were affected with echinococcus. It is also responsible for a similar cystic disease in sheep. In Australia the disease is very prevalent amongst the pastoral population, and I do not think I am exaggerating when I say that in at least 1-20th of the cases operated upon for tumours a hydatid cyst is discovered. The life history of the echinococcus occurs in two stages. One stage is a cyst which occurs in man, sheep or ox, and occupies almost any situation in the body, but is more commonly found in the liver, lungs, brain or bones. This cyst often reaches the size of a man's head. The other stage is a small tapeworm a quarter of an inch in length, which inhabits the intestine of the dog. This small worm is the sexual stage, and produces quantities of microspic eggs. These are swallowed by man or beast in drinking water which has been contaminated with the excreta of infected dogs. The eggs hatch in the alimentary canal of man, ox or sheep, and the embryo emerges and finds its way to various situations where it forms a cyst. The causal relationship of a minute worm in the intestine of the dog to a gelatinous cyst containing a gallon of fluid in the chest of a man, could, in this case, only have been ascertained by experiments upon the dog. (III.) Diseases common to man and dog have been fruitfully studied upon the latter, *e.g.*, rabies and ankylostoma. (a.) Pasteur's investigations upon rabies which led to the discovery of a means of preventing the occurrence of this disease in persons infected by mad dogs, were entirely conducted upon these animals, and could not have been arrived at otherwise, for the dog was the only other available animal in which the symptons and clinical course of the disease were at that time recognised. (b.) Ankylostoma or miner's worm is a disease seriously affecting the health of miners in many parts of Europe and Great Britain. It is due to multitudes of small parasites which attach themselves to the intestinal wall and suck the blood of their host. Until recently the way in which man became infected with these parasites was not understood. As the worms are found in the small intestine it was naturally presumed that the eggs were in some way introduced by the mouth, either in drinking water or food. All attempts to stay the extension of this disease by attention to the food and water were, however, without avail. In 1904 Loos (*Brit. Med. Assoc.*, 1904, *Mining Jl.*, *Aug.* 6, 1904), of Cairo, succeeded in demonstrating the precise channel through which these parasites affect an entrance into the human body, and succeed in establishing themselves in the alimentary canal. These experiments were made upon dogs. The ova of ankylostoma pass out in the dejecta of infected individuals. The ova hatch in the fæces and active small embryonic worms emerge. These, when placed on the skin of a dog were found to burrow through the epidermis, and were tracked into the small veins and lymphatics of the neighbourhood. Through either course they were carried by the blood stream to the venous side of the heart, and thence into the capillaries of the lungs, where they became impacted. Then they forced their way into the air cells of the lungs, and upwards into the small air-tubes, giving rise at the same time to a certain amount of catarrhal exudation. This exudation being swept upwards by the ciliary movement of the cells lining the air-tubes, the embryos arrived, after this complicated journey in the mouth of the animal and were swallowed. This demonstration of Loos (*Centralbl. f. Bakt.*, *Vol.* 33, 1903, *p.* 339) of infection through the skin was subsequently confirmed upon man by Calmotte (*l'Ankylostomiase* (*Anémie des Mineurs*) *Biologie, clinique, traitement, &c., Paris*, 1905) in France, and Boycott (*J. of Hygiene*, 1905) in this country.

11822. In the course of that journey through the man, or through the animal, do they do no moral harm to them?—No, no appreciable harm.

Mr. C. J. Martin, M B., D.Sc., F.R.S.

10 July 1907.

11823. Then they got into the mouth, and, I suppose, passed out in the fæces ultimately?—Then they go into the intestine when swallowed, and then they develop into full-grown worms, which suck blood.

11824. And then they become mischievous?—And then they become mischievous. The dog and certain species of monkey are the only animals known to be capable of occupying the position of host to the human ankylostoma. The monkeys not being available, these facts could not have been ascertained without experiments on dogs. (IV.) A much more weighty objection is that physiology in Great Britain would be very seriously handicapped if, for any reason, dogs were not available for animal experiments. This would be a calamity, for pathology and medicine are founded upon experimental physiology, and any hindrance to the development of physiological knowledge must produce a corresponding diminution in the rate of advance of these medical sciences. I cannot better express my opinion on this subject than by quoting from the evidence given by Charles Darwin before the last Royal Commission on Vivisection: "I am convinced that to hinder the progress of physiology would be to commit a crime against humanity." I realise that physiological knowledge would not cease altogether to progress because an impediment were placed upon its development in this country, but am sufficiently patriotic to wish that my countrymen should maintain that honourable place as workers in this field of science which they at present possess. The physiologist must have access to animals of varying size. For some problems experiments upon small animals are more suitable, but many important functions of the body can only be investigated upon an animal large enough to permit of the accomplishment of the necessary experimental manipulations—e.g., the physiology of the circulation, respiration, and nervous control of the same. Physiological facts derived from experiments upon animals can only be applied to man when the mechanisms in the two cases present close similarity. In the case of investigatons upon the digestive system it is necessary that experiments be performed upon an omnivorous animal. The dog, as domesticated, is omnivorous, and can be obtained of sizes varying within a considerable range, and is, therefore, well adapted for such investigations. As well as possessing the advantages above indicated, an experimental animal must be accessible to the physiologist from the point of view of price. Monkeys and apes can, on this account, only be employed for special researches, such as those upon the nervous system, where their much greater similarity to man in regard to nervous organisation renders them preferable. Owing to the fact that dogs are not utilised as food in this part of the world there is, in our large towns, a continual supply of valueless and homeless dogs, which can be procured at a moderate price. Lastly, it is desirable that an animal be of such a character that it can be kept in health and looked after in the adjuncts of a physiological laboratory. Physiological laboratories are, as a rule, in cities and attached to universities, and not usually supplied with any stable accommodation.

11825. (*Chairman.*) Then the last head of your evidence is as to demonstrations upon living animals in teaching. That we have heard a great deal of, and, of course, it is a very important question?—The study of the structure and arrangement of dead organs and tissues, even when coupled with the best of descriptions of the functions of such organs and tissues, is inadequate to supply the student with a true conception of physiological processes. The only method with which I am acquainted whereby one is enabled to explain a fact or process is by reference to other facts or processes which are already part of the experience of the pupil. Physiological phenomena are so peculiar, and often differ so essentially from those which have already become part of the experience of the student during his study of chemistry and physics, that it is impossible to convey more than a distorted conception of most processes occurring in the animal body without some direct appeal to experience. I am confident that no one ever realised many of the most elementary physiological facts without witnessing experiments upon living animals. It is not possible, nor is it necessary, that every experiment which has contributed to present knowledge of physiology should be reproduced for the benefit of the student, for when he has seen and appreciated some few fundamental experiments it is possible to assist him to an understanding of further physiological phenomena by appealing to his previous experience. The opinion expressed above was forced upon me by my own experience as a student. I first studied physiology at a medical school, where I had no opportunity of witnessing physiological experiments. My conceptions of physiological phenomena were drawn from examination of dead animals and descriptions conveyed by word of mouth and printed books. This means of study energetically pursued enabled me to reproduce descriptions of physiolgical processes to the satisfaction of my examiners and myself. Subsequently I had the good fortune to study in the Physiological School of the University of Leipzig, and to see experiments, when I found that the conceptions which I had formed of what took place in physiological phenomena were distorted, and bore little resemblance to reality. The class of physiological experiments which it is necessary to show to students involves no suffering, as they are all conducted under anæsthesia. A mongrel which nobody will provide for, and which would otherwise be destroyed by the agency of the police, is drugged to unconsciousness, and his exit from this life is made an opportunity for the conveying of cardinal knowledge of function to the student, which knowledge cannot be attained in any other way. It has been suggested that the witnessing of physiological experiments would have a brutalising effect upon the student. I have never discovered this. When professor at Melbourne I performed from thirty to forty experiments upon living animals each year during my course of lectures. This class included six or eight young ladies. What I did notice, however, was that when confronted with experiments on animals the class became interested, earnest observers, and assumed the attitude of scientific searchers after truth.

11826. (*Dr. Wilson.*) May I take it that as Director of the Lister Institute you superintend generally the bacteriological methods of diagnosing infectious disease and the preparation of the various sera, and so on?—I have merely a general administrative supervision. I have skilled bacteriologists and experts in other departments whose special duties are of a particular nature.

11827. May I assume that the experiments on animals entailed in these methods of research and for the preparation of these preventive or curative substances are almost exclusively confined to inoculations or injections?—That is so in the Lister Institute—almost exclusively.

11828. Whenever diseased conditions are produced in animals by these experiments, do you concede that the element of pain can never be eliminated altogether?—I imagine that it is not entirely eliminated, either the element of pain or the want of feeling of well being.

11829. Discomfort?—I do not know whether it is. I certainly think that in some cases there is discomfort.

11830. And in some cases where death ensues after injections there might be a good deal of pain, of course?—In some cases there may be.

11831. Would you kindly tell me the names of the substances which you prepare as toxins and sera in the Lister Institute?—Do you mean for commercial purposes?

11832. For commercial purposes?—There is diphtheria antitoxin, tetanus antitoxin, dysentery antitoxin, and Yersin's anti-plague serum.

11833. Do they prepare any vaccine lymph at the Institute?—Yes, and vaccine lymph.

11834. All these are, as you say, prepared for sale?—They are prepared for sale.

11835. Could you give me any idea of the approximate number of doses of these preparations which are sold during the course of a year. I suppose that would not come within your knowledge?—I can ascertain it for you. I could not tell you off-hand.

11836. May I inquire how much one of these large doses of anti-diphtheritic serum costs—how much is charged for it?—These are sold to the public through our wholesale agents at the rate of 2s. 6d. for 2,000 units.

11837. So that for 20,000 units?—It would be ten half-crowns.

11838. It would be 25s. for a single dose of the anti-diphtheritic serum?—It would be ten half-crowns; that would be 25s. for the amount that is the average dose administered by the Metropolitan Asylums Board people, who have the very greatest experience in this matter.

11839. And in a case of illness of average severity, how many of these doses do you think would be given?—Not more than 20,000 units altogether.

11840. During the whole course of treatment?—Yes, certainly.

11841. What would be the initial dose then?—It might be given in three or four doses within the first 24 hours; that is the usual practice, I believe.

11842. But is it not the fact that serum is given for several days in some cases?—It may be; but that is not the best way to give serum. The best way to give serum is to get a much in as possible as soon as possible.

11843. So that it may be taken as an estimate that for an average case of diphtheria about 30s. would have to be expended in treatment with this serum?—I think so.

11844. I hope you will not consider this an invidious question, but may I inquire whether you yourself and the whole of the expert staff are paid by fixed salaries, or whether the salaries depend in any way upon the amount of these products which are sold?—No, the salaries are fixed, fortunately; because the results from the sales of these products are not very remunerative, and under any circumstances it would in no way affect the salaries of the staff. As a matter of fact they do not quite pay expenses.

11845. Although I have no doubt that the horses on the Institute farm, which are used for the production of serum, are carefully vetted as to soundness, is it not the fact that these animals do not come under the Vivisection Act at all?—They do not come under the Vivisection Act as long as we are not trying to find out anything new.

11846. Nor, of course, do any of the horses used by the large manufacturing chemists for the production of sera?—Provided they are not attempting anything in the nature of an experiment. If they are only manufacturing serum for commercial purposes they are, I understand, without the scope of the Act.

11847. But as they have to be frequently injected and repeatedly bled, and the greatest care, of course, must be taken as regards their condition of health, do not you think that they should come under Government supervision?—I see no objection at all. It seems rather an anomaly that you should be able to bleed a horse for commercial purposes without supervision and not for experimental purposes.

11848. And that would apply to the calves you use for calf lymph?—Yes, for vaccine. I gather that it was merely a question of expediency in framing the Act—the difficulty to draw the line.

11849. In the production of sera in the animals themselves do not you think that, as much depends upon the purity and standardisation of all these various sera and vaccines, all establishments of the kind should be more or less under Government control?—There is no control of it in this country. In most foreign countries, there is a Government control and an establishment for standardising such preparations. But that is apparently not the way we proceed in this country.

11850. Before dealing with the results gained from all these newer methods of prevention and cure, may I ask whether you conceive that in this country, at all events, many endemic or epidemic diseases have either been banished altogether or kept under control without having recourse to experiments on animals?—I cannot remember any just now. I think it is possible.

11851. Plague, for example—we have heard so much about that?—Yes, plague disappeared from this country for reasons we do not understand in the least.

11852. We got rid of it without any recourse to experiments on animals?—Yes.

11853. And was not leprosy also common in this country?—Yes.

11854. And coming to more recent times, has not cholera been practically banished?—Yes. I do not know that cholera was ever very common in this country.

11855. There have been several epidemics about half a century or more ago. And typhus and relapsing fever have been practically banished from this country, with the exception of a few outbreaks in poor and dirty courts?—Yes.

11856. And even typhoid fever has been vastly reduced, has it not, both as regards the mortality and prevalence?—Yes. I am not prepared to say how far the knowledge obtained by experiments on animals has not contributed to that reduction in the case of typhoid fever.

11857. But I am talking of prevalence before that time?—Yes, the prevalence had diminished before. I admit that.

11858. And even with regard to phthisis, was not the mortality from that disease reduced by half, at least, before Koch discovered his bacillus?—Yes, that is so.

11859. (*Dr. Wilson.*) And now I come to a disease to which I do not find any reference in your admirable and compendious *précis*—I mean small-pox. I presume you do not question the value of vaccination as a protective against small-pox?—No.

11860. But Jenner's great discovery that cow-pox was a modified form of small-pox was made through induction, was it not, and not through any experiments upon animals?—I think you will find that he took advantage of the fact that cow-pox existed in milch cows, and was associated with cow-pox in the milkers.

11861. (*Sir William Collins.*) Can you give the reference to that?—No, I cannot now

11862. (*Chairman.*) I thought it was only that they got pimples on their hands?—Anyhow, he took advantage of observations of conditions that were ready made. There were no experiments on animals in that case.

11863. (*Dr. Wilson.*) Though calves are now almost exclusively used for the production of lymph, vaccination until very recent years was largely carried out from arm to arm, was it not?—I believe so.

11864. And could be so carried out still if all children were believed to be healthy?—Yes.

11865. But did not Pasteur found his methods of protective inoculation on Jenner's discovery, and are not all these newer protective methods to which you refer more or less based on that discovery?—I presume that Jenner's work was quite familiar to Pasteur when he discovered that an old culture of chicken cholera was capable of conferring a certain amount of immunity; but I believe it was not due to Jenner's work that Pasteur discovered that fact. I believe it was purely accidental.

11866. But do not you think he was influenced at all by Jenner's discovery?—I should imagine that he would probably have been influenced in drawing his conclusions by his knowledge of Jenner's discovery.

11867. Is not vaccine lymph, whether it is obtained from the calf by vaccination, or from arm to arm, as in human lymph, believed to be a modified or attenuated form of the virus of small-pox?—Yes.

11868. And is not that the reason why it is used as a protection against small-pox, because it is believed to be a modified or attenuated form of the small-pox virus?—I imagine that is why Jenner first used it.

11869. And is not vaccinia, or the conditions following vaccination, whether in the cow or calf or human being, also believed to be a modified form of small-pox?—Yes.

11870. So that as one attack of small-pox renders a person immune against a subsequent attack, so vaccinia, or the conditions induced by vaccination, more or less effectually protects against small-pox, is not that so?—That is so.

11871. But is not this protective vaccine manufactured, so to speak, entirely within the tissues of the living body, and cannot be cultivated outside the body, whether it be of the calf or the child?—I am afraid I do not quite understand that question.

11872. That the virus of vaccinia, the lymph, cannot be cultivated, as you do other toxins?—That is so; it has not been cultivated.

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

10 July 1907

11873. It cannot be cultivated outside the living body. Is it not entirely produced in the tissues as in the arm under the skin?—It has not so far been cultivated outside the living body.

11874. In this respect, then, does it not differ vastly from any other vaccines you name, such as tuberculin, mallein, and Haffkine's plague vaccine or Wright's typhoid vaccine?—I will not admit that it differs vastly; it differs to the extent you mentioned—that the one has not been cultivated and the other has.

11875. And all these newer vaccines are prepared, of course by cultivating the so-called specific microbe of the disease on various organic media or substances outside the living body?—Yes.

11876. Is it not the fact that while a calf which has been successfully vaccinated is rendered completely immune against a second vaccination, the serum of successfully-vaccinated calves absolutely fails to confer any immunity at all on other calves?—I think that that is to a certain extent true, but not absolutely true. Experiments have been made showing, first, that the serum of a vaccinated animal will destroy vaccine lymph when mixed with it; and, secondly, that in some cases it has been found difficult or impossible, I believe, to successfully vaccinate an animal that has had several injections of the serum of a calf that has been vaccinated.

11877. But my question was whether it has not been proved by experiments that the serum of a successfully vaccinated calf will not protect another calf against vaccination?—Yes.

11878. Does not this fact alone, which you admit has been established, cast very logical doubts upon the protective value of the various sera you have mentioned?—I do not think so, in the least.

11879. Although it must be admitted that there is a specific virus, as I call it, for all these infectious diseases, it does not follow, does it, that the micro-organism which is characteristic of any particular infectious disease, is the actual *causa causans* of that disease?—I am afraid I do not understand the distinction.

11880. You believe that the microbe is the cause, wherever you find it?—I believe in the case of a large number of infectious diseases, many of which I have mentioned in my evidence, it is undoubted that the microbe is the essential cause of the disease.

11881. Take phthisis, for example. It is now admitted, is it not, that the tubercle bacillus is not found in the early stage of the great majority of cases of the disease?—Is not found where?

11882. In the sputum?—I do not admit it.

11883. Then is not the typhoid bacillus now found in the fæces of healthy persons?—It has been found in the fæces of healthy persons, especially in those who have suffered from typhoid and are known to have suffered from typhoid.

11884. Has it not been recently found in the jejunum, even in cases of typhoid further up the intestine?—I am not aware whether it is ever found in the jejunum or not. You can get it from the small intestine in cases *post-mortem*; but it is very difficult to isolate it.

11885. Has the typhoid bacillus ever been found in polluted air?—I should imagine not.

11886. Or even in polluted water?—It has been found in polluted water, certainly.

11887. But very rarely?—Very rarely, yes.

11888. Then as you admit that typhoid fever cannot be produced by inoculation in animals, how can it be said that the typhoid bacillus is the exciting cause of the disease? You cannot by inoculation produce typhoid fever in animals?—It is true that you cannot completely reproduce the disease by feeding with the bacillus of typhoid. The evidence so far of the typhoid bacillus being the cause of typhoid fever is not absolutely complete; but its association with the disease is so constant, and the fact that it can always be recovered from the organ of patients who have died of the disease (and, indeed, it was in the first instance discovered in the organs and not in the alimentary canal) renders it so extremely probable that it is the cause of the disease as to leave little room for doubt. And, in addition to that, you have now the evidence from agglutination and the bactericidal action of the sera of patients convalescent from typhoid fever, which is entirely specific for that organism.

11889. But is not this reaction sometimes found in respect to other diseases?—It has never been found in respect to other disease to anything like the same extent or the same dilution as for typhoid.

11890. But it has been found; so it is not an absolute test?—A slight specific reaction has been found in the serum of patients which are not known to have suffered from typhoid fever.

11891. What about para-typhoid?—The serum of para-typhoid cases reacts in a high degree to the particular para-typhoid bacillus.

11892. But there is at present a great deal of confusion between the two, is there not?—I think that confusion is being rapidly cleared up by bacteriological investigation.

11893. Now, take the bacillus of diphtheria; you have admitted that that is often found in healthy throats?—Yes.

11894. And is it not often confounded with what are called pseudo bacilli, like Hoffman's bacillus?—I do not think it is often confounded nowadays.

11895. Do you think mistakes in bacteriological examination cannot be so rarely made?—I think they are rarely made nowadays.

11896. If you inject the toxin manufactured or produced from the diphtheria bacillus into a horse, are any of the prominent symptoms of the disease, as seen in the human patient, developed in the horse?—Do you mean in the course of immunisation?

11897. Yes. You inject the cause of the disease, and you believe that you produce the disease in a modified form, do you not? You never get diphtheria; you never get the throat manifestations in the horse?—No, not when you inject it under the skin.

11898. Of course, if you are to inject any stuff into the throat it will produce irritation?—Not any stuff.

11899. I will not say any stuff; I do not mean it in any sense disrespectful to the serum—but any injurious material?—If you inject any irritant into the throat it will produce inflammatory changes.

11900. Can it be said that any of the diseased conditions produced in animals by injections of toxins derived from so-called specific microbes, bear any close resemblance as regards the incubation period, for example, and train of symptoms, as in diseases propagated by infection on the usual natural lines. Do you get the real disease with it?—You get the real disease in a modified form, owing to the fact that you inject the poison all at once instead of having to wait for it gradually to be developed and be absorbed day by day.

11901. But you are never certain that some of these induced diseases have periods of incubation as in human beings. You do not get these illustrated in animals?—If you inject a toxin directly into an animal you cannot expect to have the same period of incubation as when you infect it with a disease.

11902. But if you inject vaccine lymph into the calf you get always the period of development; that is to say, a vaccine lymph vesicle is there on a particular day after?—But I would point out that the two conditions are not analogous. In one case you are injecting a poison, in the other case you are injecting a living organism which has to grow.

11903. But in injecting animals with toxins you do not, of course, inject the organisms?—No.

11904. No bacillus has been discovered yet in small-pox?—No.

11905. Has any so-called specific microbe or micro-organism been discovered, apart from small-pox, for scarlet fever?—No.

11906. Or measles?—Measles is doubtful.

11907. In whooping cough?—There are good bacteriologists who claim to have discovered the organism responsible for whooping cough within recent years.

11908. But there is not general agreement upon it?—It is not established at present.

11909. Nor, of course, in hydrophobia has any specific microbe been discovered?—No.

11910. With regard to hydrophobia, compared with other prophylactics, does it not seem very incongruous

that Pasteur should have selected the spinal cord of an assumed infected rabbit as his vaccine against hydrophobia? That is a very singular instance, is it not, of the substance that is used?—I think I am right in saying that in the first instance Pasteur used the saliva of dogs, and subsequently used the spinal cord; and I think the train of reasoning was quite clear and logical which led him to expect that he would find the virus of hydrophobia within the nervous system.

11911. But as the virus is found in the saliva of dogs, would it not have been just as logical to try to discover it in the salivary glands, for example?—He did.

11912. And failed?—He found it unsatisfactory.

11913. Although the saliva itself contained the virus?—Yes.

11914. I see in your *précis* that you have given statistics to prove the success of the Pasteur treatment. But is it not a fact that all deaths are excluded which either occur during the treatment or within 15 days after it has been completed?—Yes, they are all excluded. May I say why?

11915. Yes; I know why?—I might put why in evidence, perhaps.

11916. Certainly. I was going to ask you has it not also been made clear by statistics that a large number of deaths have occurred after Pasteur's treatment? I cannot say how many just now, but I know that in 1898—that is nearly 10 years ago—there were over 800 fatal cases which have been collected after treatment?—I am afraid I do not quite know where I am. Am I to answer that first question?

11917. Yes, certainly. Give your reason?—The reason why they excluded all cases which occur within 15 days of the termination of the treatment was that Pasteur found that the incubation period after the direct access of virus into the central nervous system of a dog was 15 days, and he did not imagine that his treatment would be of avail when the virus had once reached the central nervous system; consequently, he never expected or claimed that it would be of any value when once that had taken place.

11918. He did claim it in the first instance, did he not? He was surprised that these deaths occurred?—I do not think he ever claimed it. Anyhow, that is why they were excluded. That was what he considered to be the limits of his treatment—that if the virus had once got into the central nervous system he did not expect that he would be able to counteract it.

11919. But was not that explanation given after deaths had occurred during treatment, and within a short period after it?—I think very likely.

11920. But this differs, then, vastly from, for example, the serum treatment in diphtheria, does it not?—It has nothing in common. The principle of that is entirely different. In the serum treatment of diphtheria the serum contains a body which neutralises the toxin of diphtheria—it combines with it chemically, and neutralises it. In the case of hydrophobia it is a vaccination. You are endeavouring to accustom the tissues of the animal to a resistance against the virus of hydrophobia by educating it first of all with a mitigated virus, and gradually increasing the severity of it. It is a process of education of the tissues of the individual. The other is a mere chemical reaction.

11921. There is no certain incubation period for hydrophobia in the human being, is there?—No. The onset of hydrophobia occurs, in the larger proportion of cases, in the second month after the infection; but it may occur in the first month, and it may occur as long as one year afterwards, and I believe cases have been recorded of even longer incubation.

11922. And when injected into animals, what is the incubation period?—It varies with the virulence of the virus injected.

11923. So that you admit, I suppose, that statistics of this description have to be very carefully scrutinised before any such Commission as this?—Satistics of every description have to be very carefully scrutinised, I find.

11924. Of course, as you have said, the disease has been effectively stamped out in this country without having recourse to Pasteur's treatment?—Certainly.

11925. Now, with regard to Haffkine's prophylactic against plague, can it be said that it has had any marked effect in stemming the spread of the disease in India?—I think the figures which I have given show that it has had a marked effect.

11926. But in a very limited number of cases compared with the millions of India?—It has not been attempted in the majority of instances.

11927. Is it, or is it not, within your knowledge that within the last few years an epidemic of plague was stamped out in Egypt without having recourse to Haffkine's vaccine or any other prophylactic?—There have been several small epidemics in Egypt, and whether Haffkine's vaccine was used or not I cannot tell. That is not the only way in which you can operate.

11928. Is not the progressive improvement of sanitary conditions the only effective basis on which prevention of the disease can be carried out?—Provided we agree as to what sanitary conditions mean, yes.

11929. Is it not the fact that before Haffkine's treatment became the vogue the mortality from the disease among the European population in India was comparatively slight?—Do you mean the case mortality or the general mortality?

11930. The general mortality?—The general mortality among the European population in India has always been slight.

11931. So that any statistics applied to Europeans with regard to the effect of Haffkine's vaccine on natives would be rather misleading, would it not? You cannot compare them exactly in the same line?—I do not know that they would be misleading. They would be a small number of figures I take it.

11932. But a vast number of Europeans did go in for it voluntarily; I think Lord Curzon himself, if I remember aright, was vaccinated?—Yes, I think so.

11933. But before treatment was introduced cases of plague were comparatively few amongst Europeans?—Yes.

11934. Now there is another point. Although the isolated groups of statistics that you give appear to show that the vaccine may possess some value, inasmuch as vaccination is voluntary, and not compulsory, would not those vaccinated, believing in the vaccine, possess, as it were, more physical resistance to the disease on account of that belief?—I see no reason to suppose that that would be the case.

11935. You do not believe in faith cure—in faith being an agent?—Yes, I do. I believe in faith being an important agent. But this is not cure; this is a question of incidence.

11936. Would they not be naturally inclined to take other reasonable precautions if they went in for the treatment?—I see no reason to suppose so.

11937. But they volunteer for the vaccination, do they not?—Yes.

11938. Would you not think that they would also be prepared to take other careful precautions?—No. On the contrary, one might imagine that those who had been vaccinated would be the most careless.

11939. But they know that a good many do not escape. That element would not come in. Have not somewhat disappointing results from the use of Haffkine's vaccine induced Dr. Klein to prepare a vaccine of his own?—Dr. Klein has, I believe, prepared a vaccine.

11940. I see that you admit that attempts to produce a serum for the cure of the disease have been disappointing; but is not Yersin's serum largely relied on in the eastern dependencies of France?—It may be so; I believe it is much more used in French territory than it is in other territory.

11941. And has not Lustig's serum also found staunch advocates?—Lustig's serum has been advocated.

11942. Now with regard to Professor Wright's anti-typhoid vaccine, was not its success in affording protection to our soldiers during the South African war seriously called in question?—It has been called in question.

11943. Were not the statistics also scrutinised by the well-known statistician, Dr. Karl Pearson?—Yes.

Mr. C. J. Martin M. B., D.Sc., F.R.S.

10 July 1907.

11944. And characterised by him as somewhat misleading?—I think he disagreed as to the extent to which they justified the conclusions that Wright had drawn from them. It was a question of the extent.

11945. But they appeared to him not to support the contention that it had acted as a protective?—No, if I remember rightly they appeared to him to be less conclusive. He was dissatisfied with the numbers and the discrepancies in certain cases. But I think Karl Pearson was taking a very high standard as to what would be required of a vaccine.

11946. He took vaccination into account in making comparisons, as I have been doing?—Yes.

11947. Is it not the fact that during the Russo-Japanese war there was an entire absence of any prevalence of typhoid fever among the Japanese troops, owing to the careful sanitary and other precautions which were taken, without the aid of any such anti-typhoid inoculation?—I have not seen any account of the amount of typhoid fever in the Russo-Japanese war amongst the Japanese troops; I cannot say.

11948. But it was very trifling, was it not?—I do not know; I have not seen any account of it.

11949. You do not know whether they used any prophylactic or not?—No.

11950. Because you have just said that they do use the anti-dysenteric serum—Shiga's serum?—Yes.

11951. I do not know whether this is within your knowledge. May I ask whether any of this anti-typhoid vaccine was used to stem the spread of typhoid during the Lincoln epidemic some two or three years ago?—Not that I am aware of.

11952. Did not Wright try it in the Maidstone epidemic?—That was the first instance in which it was tried.

11953. Are not these inoculations both with Haffkin's vaccine and with Wright's followed by somewhat painful symptoms?—I think the symptoms are quite trivial.

11954. But at the outset, from the original vaccine?—In the early stage the dosage was considerably greater than is necessary now.

11955. But how do you know about its being greater than necessary? Was not the dose lessened because of the unpleasant symptoms?—No; the dose was lessened on account of the investigations undertaken under the auspices of the Anti-typhoid Inoculation Committee.

11956. By experiments?—By experiments.

11957. Then the original experiments could not have been relied on, and were not so reliable?—It is always possible to improve things as you learn more and more about them. And, in the first instance, as I have pointed out in my evidence, Wright was suddenly confronted with the vaccination of a mass of troops in South Africa, owing to the great prevalence of typhoid fever there, and had to put a process into use which no doubt he would gladly have proceeded with more slowly and improved his methods.

11958. Would not a great deal depend upon the particular strain of bacillus that might be cultivated?—I think not.

11959. Would that apply to any serum that might be produced as regards the strain of bacillus that must be used either for producing the vaccine or the serum. Is it immaterial?—It is generally held that it is more advantageous to use a bacillus of considerable virulence. But those are points which are not definitely determined.

11960. Has not Professor Wright recently made rather a damaging pronouncement concerning the serum treatment?—I should think it is very likely.

11961. Does he not now strongly advocate treatment by vaccine and not serum, as indicated by what he calls the opsonic index?—I believe that is so.

11962. Do you think that this new departure in bacteriological treatment can ever become possible in general medical practice, even if it should be proved to be successful? Could it be possible for medical practitioners, I mean, to take this opsonic index into practice?—I think it would be difficult for busy medical practitioners. But, if it were found essential, it will always be possible to find people capable of doing it.

11963. I come now to tetanus. Is it not the fact that the treatment of tetanus by anti-tetanic serum has fallen into disrepute?—I would hardly agree with you that it has fallen into disrepute. It has not justified the expectations.

11964. But it was first tried by injecting it under the skin, subcutaneously, was it not?—If I may put it this way: although I consider that you are treating tetanus at a very late stage of the disease by the time you have got symptoms of spasms, it would still be my duty to administer the anti-toxic serum.

11965. Then would you administer it by injecting it under the skin, or under the dura mater after trephining the patient, as has been done in some cases?—I should inject it intravenously. I have done so on more than one occasion.

11966. And not under the skin or under the dura mater?—No.

11967. You referred to puerperal fever. Has not the anti-streptococcus serum treatment for puerperal fever also been more or less a failure?—It has been unsatisfactory, owing to the fact that it is highly specific, and puerperal fever is caused by a great variety of different strains of streptococci. You are never sure that the serum will be made from an animal immunised with an homologous strain.

11968. But were not great expectations held out with regard to it at first?—I cannot help that.

11969. Can it be said that though pneumonia is one of the most prevalent of diseases, the anti-pneumonic serum has in any sense become popular as a remedy?—No, I think not.

11970. Does it not appear somewhat singular that anti-tetanic serum, for example, which was first used as a remedy should recently be almost exclusively used as a prophylactic?—No; it seems to me to be perfectly clear why it should be so.

11971. Why was it not so used in the first instance? They started it as a cure, did they not, and not as a prophylactic?—They did not find out the limitations until they had used it.

11972. That is to say, they did not use it as a prophylactic until they found that it failed as a cure?—No, that is not quite so; because it was used as a prophylactic in animal experiments in the discovery of it, the working out of the process.

11973. Even as a preventive of tetanus in animals, it was not used for some time?—I think it was; I think that was one of its first virtues that was discovered—its prophylactic value.

11974. It was not used as a prophylactic in tetanus at first?—I am not aware whether that was the case in practice or not.

11975. But in spite of the statistics supporting its claims as a preventive, it does not follow, does it, that the great majority of men or animals, in which it is used, would have developed tetanus if it had not been used. You cannot say that?—If you will leave out the first part, I could understand it.

11976. Very well, I will put it in this way: that we will suppose horses or people have abrasions, and that you use this serum for all of them to prevent the disease; it does not follow, does it, that any or many of them would have had the disease if they had not been injected?—It does not follow that every horse that has abrasions will become infected with tetanus. I prefer to put it in that way, if I may.

11977. May I ask whether anti-tetanic serum was used to prevent the disease occurring among the wounded during the South African War?—Yes.

11978. To a large extent?—There were only three cases of tetanus.

11979. But was that due to the use of the serum or to clean surgery?—It was due to clean surgery.

11980. And you cannot say whether the serum was largely used or not?—Whether the serum was used in those cases or not I am unable to say.

11981. But I mean generally amongst the wounded?—I do not think so. There was a large amount of serum taken to the South African War, but I do not suppose it was used. As a matter of fact they had no tetanus except three cases, and it would not have been generally used.

11982. You point out that in the Franco-Prussian War there were ·35 per cent. cases amongst the wounded?—Yes.

11983. And that was before the days of clean surgery?—It was before they knew how tetanus was transmitted, or what its causation was.

11984. So that after all is not the chief preventive against tetanus, to ensure that wounds are washed clean and kept as clean as possible?—Yes.

11985. Now I come to the much vexed question of the serum treatment of diphtheria. Of course, the antidiphtheric serum is believed to be the most successful of all sera in treatment, is it not?—Certainly.

11986. And that is not quite a harmless product, is it?—It is not quite harmless.

11987. It produces rashes in a great many cases?—Yes.

11988. And other disagreeable symptoms?—The most disagreeable symptoms are the rashes. They keep the child awake at night.

11989. Are not medical men encouraged to use it in all suspected cases of throat illness, and not to wait for the results of the bacteriological testing for the bacillus?—I think that is quite a wise procedure.

11990. But if the bacteriological testing fails to confirm the suspicions of the medical attendant and the case does not turn out to be one of diphtheria, would you not call this somewhat haphazard treatment and scarcely fair to the patient?—No. I should consider it had been done in the best interests of the patient, for the reasons given in my evidence as regards the necessity of the earliest possible treatment by all antitoxins.

11991. If it does not turn out to be diphtheria?—No harm is done.

11992. But you admit that it causes rashes?—The patient does not die of the rashes.

11993. How long does it generally take before the medical man receives the bacteriological report, after forwarding a swab from the throat of a suspected case?—Fourteen or fifteen hours.

11994. But supposing you have to send to the country by post?—You can telegraph the result.

11995. But the swab has to be sent?—Say from 14 to 24 hours, in this country.

11996. But as there are several other bacilli closely allied to Loeffler's bacillus, can the bacteriologcial testing be regarded as absolutely reliable without having recourse to the guinea pig?—Not absolutely; but it is a near approximation to the truth, which is of great value for practical purposes.

11997. How long would it take to complete a test for injecting a guinea pig?—About four days.

11998. In relying upon the bacteriological testing, is not the medical attendant placed in a somewhat invidious position; does not the delay in waiting for the report rather militate against the chances of cure?—I have just previously stated that I thought the injection of the serum in the case of a patient that was suspected to have diphtheria was the best treatment in his interest.

11999. But then that would be dispensing with the testing altogether?—No, because you can inject one dose. The earlier you can treat with antitoxin the less is necessary. You can give a moderate dose of antitoxin and then if the diagnosis is confirmed on the morrow by bacteriological examination, you can give more. If it is not confirmed you would give no more.

12000. But then you must admit that this waiting for the report of the bacteriological testing does militate somewhat against the chances of cure?—I advise not to wait.

12001. Then the testing could be dispensed with?

12002. (*Sir Mackenzie Chalmers.*) Are there not in a great many cases well-known marks which no medical man can mistake?—Yes.

12003. When you see the false membrane and the other symptoms?—Yes.

12004. (*Dr. Wilson.*) But the false membrane does not appear within a day or two, does it?—Not as a rule.

12005. Now the success of the diphtheritic serum treatment in this country is based, is it not, mainly on the cases admitted into the London isolation hospitals before and since the introduction of the serum treatment?—No; I have given a large number of tables from many other places.

12006. I am going to refer to some of those. You have admitted, I think, that if, for example, the type of the disease had become much milder in London since the serum treatment was commenced, that would influence the statistics somewhat, would it not?—I have stated that in my evidence about it.

12007. It would lessen their value. I think you have also stated that the bacteriological testing rather tends to make the cases appear more numerous, because slight cases are notified now which would not have been notified in old days?—I have suggested that that may very possibly happen.

12008. But if the death-rate per thousand of population has gone up in spite of the antitoxin treatment during the past ten years as it has, that surely could not be regarded as a statistical result in favour of the serum treatment, could it?—It could not be regarded as a statistical result in favour or against.

12009. Granting that the serum does assist in freeing or loosening the diphtheritic membrane owing to the reaction which it produces, and its effect on the circulation and minute blood vessels under the membrane, can it be said with certainty that its after effects are so beneficial as they are believed to be? I admit that it may have an effect?—I do not know how beneficial they are believed to be.

12010. You believe that the results of the treatment are beneficial, and you gauge them by figures?—Yes.

12011. For example, in your *précis* you state that paralytic symptoms are more common now than they were before the serum treatment?—Yes.

12012. And you hold that that is an argument that severe cases survive which would have proved fatal had not the serum been used?—I suggest that that is a possible explanation.

12013. Might I not also suggest that a possible explanation may be that, admitting that the serum may possess some action in assisting in loosening the membrane, its after effects may increase the number of paralytic cases?—You may hold that opinion, Sir.

12014. But is it not as logical as the one you have mentioned?—I have adduced some reason for my opinion; you have not done so yet for yours.

12015. I will not labour this point further. Though the general death-rate from the disease has gone up, the case mortality rate in the county of London, according to the statistics which you furnish, has gone down from over 20 per cent. in the pre-antitoxin days to about 10 per cent. in the last few years. That is correct, is it not?—That is correct.

12016. I see also that you refer to the statistics collected by Dr. Armstrong, Medical Officer of Health for Newcastle, in various towns in the north, centre, and south of England. You give that table?—Yes.

12017. These statistics show, do they not, that although there has been a reduction in the case mortality rate, it is not nearly so marked as it is in London?—That is so.

12018. And you attribute this, do you not, to the fact, or to the assumption, rather, that the antitoxin was not so freely used in these other towns as in London?—I think that is a probable interpretation.

12019. But is it not the fact that almost all medical men now use the antitoxin?—I think the majority of medical men use the antitoxin. But of that I have no way of judging except by the amount of antitoxin which is sold.

12020. Now I have here a very short extract from a paper recently published, which was read at a sessional meeting of the Sanitary Institute by Dr Hibbert, who is Dr. Armstrong's deputy in Newcastle, and is also physician to the isolation hospital. In that paper he deals with the statistics which you have collected, but groups them in a different form. For example, during the five years from 1900 to 1904, in eighteen northern towns the average case mortality rate was 24·7 per cent., in five midland towns it was 15·7 per cent., and in eight southern towns 13·1 per cent.; and in London you say it is now 10 per cent.?—Yes.

12021. That table shows, does it not, that even during the years 1900 to 1904 the case mortality rate of diphtheria was even higher in the eighteen northern towns than it was in London before the serum treatment was introduced. For example, before the serum

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

10 July 1907.

treatment was commenced in London it was about 24 per cent.?—Yes, 20 to 24 per cent.

12022. And in the eighteen northern towns during these recent years, 1900 to 1904, it was as high as 24·7?—No, not quite; 18 in 1904 and 22·7 in 1900.

12023. Now he also makes these remarks in his paper:—"I may add that at the City hospital here" (of which he is physician), "where antitoxin in doses of from 6,000 to 12,000 units is given as a routine treatment, Dr. Harris and myself have not had evidence that antitoxin is the definite curative agent which it has apparently proved itself to be in the hospitals of the Metropolitan Asylums Board. There is, however, this fallacy as regards diphtheria statistics, that at least one southern town" (he does not name the town) "includes amongst its cases of diphtheria those 'contacts' in whose throats the bacillus is found, but who do not show any clinical symptoms of the disease." Does not this statement somewhat qualify your inference that the much higher case mortality in the northern towns is probably due to the fact that antitoxin is less used there. You see that they use it freely?—I am unable to say unless I have more data.

12024. I am quoting from this paper?—I am not complaining of the data that you have given me. I do not think the statement of this gentleman necessitates a modification of opinion on my part.

12025. But no medical practitioner, so far as I know, dare neglect the use of serum nowadays?—I am very glad to hear it.

12026. In country districts the parson would be down upon them, and the country squire would be asking why the serum was not used. As you quote several diphtheria statistical tables from Continental records, as well as from American records, I will now ask your opinion about some records which are given by the Medical Officer of Health of the City of Toronto, in his report for 1904, based on the diphtheria cases which were treated in the city hospital for ten years. It appears that there have all along been doubts among medical men there concerning the efficacy of serum—that is, in Toronto, and groups of unselected cases were treated in the hospital, some with antitoxin and some without, during those ten years; and this is a summary of the results for ten years. He says: "Since 1894, when the first dose of antitoxin was given at the hospital, the mortality results have almost always been unfavourable. In every year, save one, the percentage of deaths in antitoxin cases has even been higher than the ordinary hospital rate, which is of course influenced by the increased antitoxin mortality. In 1894 the figures were respectively 21·4, against 14·07, and this state of things continued without much improvement until 1902, when the antitoxin was about 1 per cent. under the gross hospital rate." Then he gives the statistics for 1903:—

	Cases	Deaths	per cent.
Total hospital admissions -	565	65	11·5
Antitoxin treatment - -	228	37	16·2
Ordinary treatment - -	337	28	8·3

But then he goes on to observe, "The statistics of the last decade, which can now be presented, embrace a sufficient number of cases on which to base a fair opinion of the value of antitoxin in hospital practice.

	Cases	Deaths	per cent.
Total hospital admissions	5,100	667	13·0
Antitoxin treatment -	1,132	181	16·0
Ordinary treatment -	3,968	486	12·2."

And then he says, "In a report of this kind any speculations as to the cause of the pronounced failure of a remedy from which so much was expected would probably be deemed out of place. A bare statement of fact is therefore presented, and this can, if necessary, be supplemented or substantiated by a large accumulation of original and classified evidence of unquestionable reliability." Do you accept that report?—Not without examination.

12027. (*Dr. Gaskell.*) Have you seen that report before?—I have not seen that report before.

12028. (*Dr. Wilson.*) You also believe that the serum is effective as a prophylactic?—Certainly.

12029. Would you recommend, then, that it should be used in every household, as they use vaccination, when a case of diphtheria crops up?—I should always use it as a prophylactic injection to any of my own children if one of them took diphtheria.

12030. But doctors do not inject themselves who attend cases of diphtheria, do they?—I imagine not.

12031. Now with regard to the anti-dysenteric serum; is that used in India, do you know; has it been taken up in India?—No, it has not been used in India to any extent.

12032. (*Mr. Tomkinson.*) How long were you in Melbourne?—Seven years.

12033. And with the exception of your experience there you have performed no experiments of a physiological kind upon animals?—Yes, I held a licence before I went out to Australia, in 1889 and 1890 in this country.

12034. I thought you said that that was the only case; perhaps I was mistaken. You there performed 30 or 40 experiments on living animals?—That was in connection with my lectures each year.

12035. And more besides?—A great many more besides.

12036. But, with the exception of that experience at Melbourne, have all your researches in the pursuit of science and discovery been confined to inoculation?—Oh, no.

12037. With regard to tetanus and hydrophobia, there is no claim that any cure of either has been discovered, once the disease has been established?—No, I make no claim.

12038. I think you include tetanus among the diseases which are occasionally cured. You say, "Unfortunately, the useful application of antitoxin serum therapy is at present limited to a comparatively few diseases; the most important of these are diphtheria, tetanus, and epidemic dysentery"?—It is usefully applied to prevent tetanus during the period prior to the development of symptoms.

12039. As a preventive, of course, I quite understand it. I thought you meant that it was usefully employed in the cure?—No; in the case of tetanus it is a prophylactic.

12040. And you claim that the use of this antitoxin or serum, or whatever is applied to either man or horses, is a prophylactic against tetanus?—Yes.

12041. I suppose you admit that that to a certain extent is guesswork?—No, I do not admit for one moment that it is guesswork. I submit that it is capable of scientific demonstration.

12042. It is a negative proof that tetanus does not follow in certain cases in which it is applied?—You are referring, I imagine, to the statistical evidence that it occurs in a certain number of wounds of a particular kind, and if you give tetanus antitoxin as a prophylactic it does not occur at all. I do not consider that that is guesswork. But, moreover, it is founded upon absolute demonstration. You can take a hundred animals and infect them with tetanus, and if you apply the prophylactic immediately not one in that 100 will develop the disease. Whereas if you take 100 similar animals and infect them with tetanus, and do not apply a prophylactic, they will all die of the disease. I call that the simplest form of scientific demonstration, apart from guesswork.

12043. (*Dr. Gaskell.*) In that case you speak of its curing disease?—It is really curing disease, because you apply the remedy after the infection, and before the manifestation of the symptoms.

12044. (*Mr. Tomkinson.*) In your *précis* you describe the treatment of a horse for antitoxin, and the effect upon the horse. You say, first of all, "It is carefully tested as being a healthy horse"; and then, "The first injection of the toxin may be followed by swelling at the site of inoculation, loss of appetite, general malaise, and rise of temperature." Have you often studied horses under this treatment?—I have seen a large number of horses under this treatment.

12045. Does the horse seem to suffer very much?—No, I think not.

12046. Is there great wasting?—Not at all. The horses compare favourably with those in anybody's stable. They are all fat and shiny.

12047. Have you seen the picture of the Khartoum dog?—I have.

12048. Do you consider that that would be the average result of certain inoculations?—It does not represent the condition of our horses.

12049. I suppose not, not from the description you have given of the horse, I am glad to hear. I wanted to know whether there was any suffering in the horse approaching the suffering that that dog had obviously had to go through?—No, nothing of the kind. There is no evidence that the horse during the process of immunisation suffers more than the man does who drinks too much the night before, say, and has a headache and general unsteadiness in the morning, and is off his feed. I should think that would put it in a simple, practical way.

12050. I see that you are strongly opposed to a limitation of the choice of animals for purposes of experiment?—Yes

12051. Because you say that dogs and monkeys, being in many respects nearest to man, are the most useful subjects for experiments?—Yes. I place particular emphasis on the accessibility of the animal for the physiologist.

12052. I suppose in all the experiments that you have performed of the minor kind, the animals have not been subject to anæsthetics?—Not in the inoculations.

12053. May I ask, are the laws regulating the practice of vivisection in the Colonies at all akin to ours?—They differ in different countries. In New South Wales, where I was for some years, there is no law.

12054. There is a law, I suppose, for the prevention of cruelty to animals?—Yes, but there is no vivisection clause in it.

12055. Then there is no immunity or permission given to vivisect?—No; it was not supposed that anybody would want to vivisect when they framed the law.

12056. And it would be a breach of the law prohibiting cruelty to animals?—No; there was nothing to prevent us performing any experiments we liked for scientific purposes in the University in New South Wales. There was no Vivisection Act.

12057. (*Sir Mackenzie Chalmers.*) There was no regulation?—There was no regulation of vivisection.

12058. (*Mr. Tomkinson.*) But there was a law for the prevention of cruelty to animals in New South Wales?—Yes. If anybody had supposed we were cruel they might have prosecuted us under that Act.

12059. (*Sir Mackenzie Chalmers.*) Nobody thought of that?—Nobody did.

12060. (*Mr. Tomkinson.*) Was there a Vivisection Act in Melbourne?—In Melbourne there was a clause in the Cruelty to Animals Act allowing the Governor in Council to give a licence to such persons as he thought advisable to perform experiments on animals; and that licence in my case included myself and every thing done in my laboratory for which I was responsible.

12061. Were you the only person to whom it was granted?—No; there were some few other persons. The pathologist and the bacteriologist and others in connection with the scientific Departments of Agriculture and Stock also held licences.

12062. Was the use of anæsthetics imposed by that licence?—Not necessarily. The licence was a comprehensive one, and in returns one had to fill in what one did.

12063. And, as a general rule, did you use anæsthetics?—Not for inoculations; always for physiological experiments.

12064. Did you find it easy, or at all events, possible, to keep the animals perfectly anæsthetised for a considerable time—as long as you wanted?—All day if one wished. There is no difficulty.

12065. (*Dr. Gaskell.*) Tetanus is a very painful disease, is it not?—I imagine so.

12066. With regard to the production of antitoxin for tetanus, is any pain connected with it?—No, not the proper production of antitoxin.

12067. (*Sir Mackenzie Chalmers.*) In the commercial production?—No.

12068. (*Dr. Gaskell.*) Would you tell us why there is no pain connected with it, because it has been put before us that there is pain connected with the production of antitoxin?—Because you never produce tetanus when you are immunising a horse.

12069. And short of producing tetanus, what is the case?—Nothing more than a slight rise in temperature and general *malaise* following each injection, which I have referred to in my evidence.

12070. I wanted to bring out simply that that applies to tetanus as well as to other things?—That is so.

12071. There is another question that I want to know about, too, and that is, what precautions are taken nowadays with respect to plague antitoxin—firstly, as to being sure that it is free from other deleterious products; and, secondly, as to standardising it. It has been said that the plague antitoxin has been out of favour in India, and would not be recommended on account of the want of precautions being taken in preparing it, and also the inefficiency of standardisation. Can you give me any information upon that subject?—The same precautions exactly are taken as with every other form of antitoxin to render it sterile and free from any contamination whatever. The reason why the plague serum is out of favour, as you phrase it, is, that it is not of very great value, unfortunately. Although it is the only rational remedy we have, it is impossible at present by injecting plague bacilli into the horse to make it respond by the manufacture of a sufficient amount of immunising bodies to be of great practical value. It is very weak compared to such sera as diphtheria and tetanus, and to that extent it is a disappointment.

12072. (*Sir Mackenzie Chalmers.*) You are referring to Yersin's serum?—Yes.

12073. (*Dr. Gaskell.*) In reality when bottles are sent out you cannot be quite sure that the standard dose put upon them is accurate. Is not that so?—I do not think there is any difficulty about that, because when you have a remedy that is too weak you give as much as you can of it.

12074. (*Sir Mackenzie Chalmers.*) You have told us that the work of the Lister Institute consists in preparing commercial sera and antitoxins. Is there any scientific work done there as well?—Yes, certainly. The preparation of the antitoxins that are of established value is only a very small part of the functions of the Institute. Practically the whole energies of the Institute are devoted to research work.

12075. How many people are working there?—I think there are about 25.

12076. Are any special lines of research going on now?—Yes, everybody is doing something or other.

12077. Merely inoculation work dealing with infective disease?—No; there is a chemical side to the Institute, where various chemical problems connected with biology are investigated.

12078. Does that involve animal experiments?—That may or may not be concerned with animal experiments. Often it is not.

12079. May I take it generally from your evidence that in your opinion research on the lines of the Institute cannot be carried on without animal experiments?—Most certainly. The Institute would have to go elsewhere if animal experiments were not permitted by law. It would have to go to one of the Colonies or America.

12080. You yourself have been on this Plague Commission, I think?—Yes.

12081. And you have been in India?—Yes.

12082. And were working there. What is the number of persons on the Plague Commission?—I think there are eight doctors.

12083. How many assistants?—I think, taking the minor assistants, it must amount to one hundred.

12084. Are all those people continually exposed to the virus of plague?—Yes, more or less.

12085. What precautions have been taken to secure them, if any?—They were inoculated at regular intervals.

12086. With Haffkine's prophylactic?—With Haffkine's prophylactic.

12087. Were they inoculated once a year?—They were inoculated more frequently than that, I think.

12088. Among your eight doctors who are continually handling this virulent material, how many cases have you had of accident?—None amongst the doctors.

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

10 July 1907.

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

10 July 1907.

12089. Yet from the nature of your experiments I suppose you are continually in contact with the poison?—Yes. They take reasonable precautions so as not to get it inside themselves.

12090. One of them, at any rate, has had some abortive attacks of plague, has he not?—One of them suffered from what is called pestis minor. I did not mention that.

12091. However, no effects followed. The prophylactic was effective?—Yes.

12092. How far was it effective among the native assistants?—To my knowledge there have been three cases of plague amongst them.

12093. Fatal or non-fatal?—They were non-fatal.

12094. Therefore amongst several hundred people in continual contact with this disease, the Haffkine vaccine has been a successful prophylactic?—I can only say that they did not die of plague.

12095. And they had every opportunity?—How far that is to be attributed to Haffkine's prophylactic can only be found out by dealing with a larger number of figures.

12096. The statistics are too small?—They are too small for me to attach importance to.

12097. Still, from your own experience, do you think it is right or superfluous to inoculate with Haffkine's vaccine these people specially exposed to the plague?—I can best answer that by saying that I have been always careful to inoculate myself.

12098. More than once?—Yes.

12099. It produces, I suppose, for two or three days a great discomfort?—Not at all. In my case it produced no discomfort, because I went about it in a gradual way, taking a very small dose in the first instance, and the next week a little more, and so on, which is the best way to immunise anybody.

12100. Just as you would a horse?—Yes, just as you would a horse; the dose was small to begin with, and gradually multiplied. I was never in the least incapacitated either in the way of appetite or my ordinary occupation. I had a slight soreness.

12101. When a strong prophylactic dose is given there is generally for two days discomfort, is there not?—Yes, but it is very seldom that it would incapacitate a European from going about his ordinary business. Occasionally it happens that a man for some reason or other is distinctly invalided, say, for 30 hours; but that is unusual.

12102. It does not take place if the inoculation is carried out gradually?—No, it does not take place then.

12103. Your experiments in India with plague have been animal experiments, of course?—The experiments have been entirely on animals.

12104. And you have as the result of those experiments discovered, at any rate, the common mode of transmission of plague?—Yes, I think so.

12105. Namely, by the rat flea, as you say?—Yes.

12106. You would hardly say that that is the only mode?—It is not the only possible mode; but the evidence adduced by the Commission is such as to lead one to regard it as the only serious mode of epidemic spread.

12107. Therefore, at any rate, you have accomplished this by your experiments—that you know the evil to be dealt with?—Yes.

12108. Though you have not yet succeeded in discovering anything like a remedy after the outset of the disease?—No, not yet. Whether it is possible to satisfactorily interfere is another question.

12109. Still is it or is it not an important step to know the means by which a disease is communicated from one person to another?—I think it is an essential step.

12110. And that you say cannot be obtained without the use of animals for experiment?—No.

12111. Incidentally, if the rat flea is the ordinary way of communicating the disease, how is it that doctors continually handling these animals in transferring the fleas from one to another, were not bitten?—I imagine they were occasionally bitten. For one thing, they wore top boots.

12112. But in combing out the fleas, to take them from one animal to another, I mean?—The animal was chloroformed and the fleas were chloroformed. Otherwise it would have been impossible to have dealt with them; the Commission would have been exterminated.

12113. But you think there must have been occasional bites, and do you attribute the immunity to the prophylactic or not?—I attribute some of the immunity to the prophylactic.

12114. (*Chairman.*) Why did you say the flea was chloroformed?—The animal and the flea. If they were getting fleas off the animal they would put the animal in a receptacle with chloroform vapour, and that quiescent sent the animal to sleep and the fleas to sleep, and one could then pick them off at one's leisure.

12115. (*Sir Mackenzie Chalmers.*) And then apply them to another animal?—The fleas recovered from the anæsthetic in a few minutes, and they could then be dealt with as wished.

12116. Is it known at all how a flea biting either an animal or a human being can deposit the plague bacillus?—It is known that the flea whilst biting commonly discharges from behind.

12117. In the process of biting?—Nearly all suctorial animals whilst sucking blood at one end discharge the contents of the intestine at the other, and in that way they can discharge infection.

12118. Then the discharge of the intestine gets on to the puncture?—Yes.

12119. And that is the mode of entry?—That is the probable mode. It itches and you rub it.

12120. It is exactly the same with an animal?—Yes, the same with an animal.

12121. (*Chairman.*) Is it the discharge that gets into the wound?—I can only say that that seems the probable way in which infection actually takes place. The fact of the soiled proboscis is not excluded, but as infection may take place as much as fifteen days after the flea has fed upon the infected animal, during which fifteen days it has been fed upon the blood of a healthy animal every day, that practically excludes the soiling of the proboscis as the means of inoculation.

12122. (*Dr. Wilson.*) Does that apply also to the mode of infection conveyed by the mosquito in malaria?—No, it is more elaborate and more perfect in the case of the mosquito; because in the malaria parasite you have two stages, one which lives in the mosquito's body, and one which lives in the blood of man. The stage that lives in the mosquito's stomach ultimately breaks up into a large number of eggs, so to speak, which get into the salivary glands of the mosquito and are directly discharged with the saliva when biting.

12123. (*Chairman.*) But that discharge which you speak of from behind is common both to the flea and the gnat?—Yes.

21124. Only it is deposited further off the wound in the one case than in the other, I suppose. The gnat's body is very perceptibly longer than the flea?—Yes.

12125. (*Sir Mackenzie Chalmers.*) The gnat actually injects the poison?—Yes.

12126. The flea merely deposits it close by?—That is what we imagine is the usual case.

12127. There is no reason for thinking that the mandible of the flea is charged with infection?—There is the reason for not thinking it that I have just mentioned—namely, that the infection will remain for fifteen days, and the flea, being fed upon a healthy animal each time, would wash its proboscis, which practically excludes this mode of infection from practical politics.

12128. By means of experiments on animals have you discovered at all the length of the prophylaxis conferred by Haffkine's vaccine?—I do not think that there are very accurate data. The Commission has not concerned itself with that problem. There is certainly some immunity left in animals, and also apparently in man after twelve months from some of the statistics which were collected by Bannerman.

12129. Can you draw any general inference from the length of prophylaxis in an animal to the length of prophylaxis in man?—Only in a rough way.

12130. Is the incubation period the same in man as in animals?—Roughly speaking, everything takes place more rapidly the smaller the animal.

12131. The guinea-pig displays plague sooner after inoculation than the monkey, for instance?—Yes, all processes take place much more rapidly in small animals, so that everything goes a little quicker.

12132. (*Chairman.*) How about the flea. What is the period of prophylaxis?—The flea does not suffer.

12133. (*Sir Mackenzie Chalmers.*) The flea takes its plague as a food?—The flea is a mere passive transmitter.

12134. Is the Commission still at work, or has it completed its work?—It has completed what it undertook to do in the first instance, and it is now resting during the hot weather. The Committee have suggested to the Government of India certain other matters which it considers it would be advisable to investigate, and has expressed its willingness to do so if it is wished.

12135. It has issued one report?—It has issued an interim report: A second will be ready to-morrow, and there will be about three others, which will be more bulky, which deal largely with epidemiological matters and the analysis of a very large amount of evidence, which takes a long time.

12136. But, in your opinion, is it still important that further experiments should be made; or do you think that experiment has done its work, and it is no longer necessary to use animals for plague experiments?—I would not say that for one moment. I do not know what may be necessary to-morrow or next month. I do not know how knowledge is going to grow.

12137. There is only one other question that I think I need trouble you with. As regards the Khartoum dog which was referred to, I imagine that people who die of trypanosomiasis would be attacked exactly the same as that dog, and look as miserable in a photograph?—Yes, the people who die of sleeping sickness very closely resemble that dog.

12138. It is not a very suffering disease in the later stages, is it?—No; but that particular trypanosomiasis was a disease of mules, which was being investigated.

12139. For the purpose of finding a cure and preventing these animals from suffering from it?—First of all for ascertaining what the disease was, and then if possible how one could best prevent it by sanitary means, or cure it if possible; and dogs were used rather than mules, as being convenient and cheap in Khartoum.

12140. The only means of eventually combating the disease being to get exact knowledge as to its nature and its mode of transmission as your first starting point?—That is the case.

TWENTY-SEVENTH DAY.

Wednesday, 17th July 1907.

PRESENT:

The Right Hon. The Viscount SELBY (*Chairman*).

Colonel The Right Hon. A. M. LOCKWOOD, C.V.O., M.P.
Sir W. S. CHURCH, Bart., K.C.B., M.D.
Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir J. MCFADYEAN, M.B.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. A. J. RAM, K.C.
Mr. W. H. GASKELL, M.D., F.R.S.
Mr. J. TOMKINSON, M.P.
Mr. G. WILSON, LL.D., M.D.
Captain C. BIGHAM, C.M.G. (*Secretary*).

Mr. C. J. MARTIN, M.B., D.SC., F.R.S., recalled; and further Examined.

Mr. C. J. Martin, 17 July 1907.

12141. (*Sir Mackenzie Chalmers.*) There was one question that I forgot to ask you last week, arising out of your plague experiments in India. If I understood you aright, your experiments established that the ordinary bubonic form, excluding the pneumonic form, is not infectious?—Our experiments did not establish that. It was established by the clinical experience of the plague in India.

12142. It is quite consistent with your experiments with respect to infecting animals, when you excluded the fleas?—Yes.

12143. It had been established before, by clinical experience, that plague is not infectious and barely contagious?—In order that there should be no misapprehension as to what is meant by the words infectious and contagious, I might say that the evidence from the experience of plague in hospitals in India and in houses in India is that it does not spread from one patient to another, provided that it is confined to the bubonic form.

12144. Your experiments with animals confirmed that?—Our conclusions, from our experiments, are consonant with that experience.

12145. You would not put it higher than that?—No.

12146. You have been a professor of physiology?—Yes.

12147. But you are yourself a medical man, holding medical degrees?—Yes.

12148. A question has been raised as to whether licences and certificates under the Act ought to be granted to people who have no medical qualifications. What is your opinion on that?—I think there is no reason whatever why those persons should be excluded, provided that they are suitable investigators.

12149. Have you the same guarantees for character and humanity in their case?—I think so.

12150. You think that persons who are what I may call pure physiologists ought to have licences?—I think the pure physiologists are quite as humane as the doctors.

12151. But have the certifying authorities the same guarantee in that case? That is rather a difficulty. Of course, in the case of a medical man, he belongs to a great profession, and you have a hold on him that you have not in the case of men belonging to no recognised profession?—I think that the certifying authorities can easily acquire the necessary information.

12152. There are, I believe, distinguished physiologists who are not medical men?—The Professor of Physiology at Cambridge is not a medical man—one of the most distinguished physiologists in this country.

12153. Generally have you any alterations that you would suggest, from your experience, in the existing law and practice?—On the whole I am content with the working of the present Act, but I would take exception to the recent action of the Home Office in not extending a licence to foreign scientists wishing to work in our laboratories.

12154. Would you kindly give us your grounds for that; it is an important question?—First of all, we were all of us indebted years ago to foreign laboratories for the hospitality they afforded us; and there is a general brotherhood amongst scientific men in Europe and America, so that if one wishes to learn something in particular one goes to the man who has devoted his life to that particular subject, and one can go to his laboratory and learn his methods and whatever he is able to teach one. That recent action of the Home Office has prevented any foreign scientist from coming to England to learn from us.

12155. (*Chairman.*) Do you think that it might lead to retaliation on the part of foreign laboratories?—No, I do not think it would lead to retaliation. I think there would be too much sympathy with our disabilities for that.

12156. (*Sir Mackenzie Chalmers.*) May I put this to you as a difficulty which the Home Office might feel? In the case of an Englishman he is well aware of the prevalent English feeling on the subject of experiments on animals, and there is certainly an idea that foreigners are less careful of animal suffering than Englishmen?—I think that difficulty could be got over by placing greater responsibilities upon the heads of laboratories.

12157. That is what I wanted to know. Can you develop that at all; can you suggest what form it should take?—The form of licence that I had in Victoria grants that in principle. That licence included the head of a laboratory and such persons as he made himself responsible for; and he returned to the Government everything.

12158. He reports everything?—He reports everything.

12159. He is responsible for the whole of the work done in his laboratory?—He takes that responsibility; the head of the laboratory must take that responsibility.

12160. You think that under those conditions there

would be no objection to granting licences to foreigners who had proved character and qualifications?—None whatever.

12161. You would make the English head of the laboratory responsible for all the work done in his laboratory, and would only allow the foreigner to work under that particular specified licensee?—I think that would get over the difficulty. In the case of my own laboratory I certainly regard myself as responsible for the carrying out of the Act.

12162. That the law is honestly and carefully observed?—Yes, in my own laboratory.

12163. Whether you are experimenting yourself or anyone is experimenting under your supervision?—Certainly.

12164. (*Sir John McFadyean.*) I want to direct your attention to Question 11924 of your evidence, given on the last day. It was put to you in the form of an affirmation, but I take it that it was intended as a question: "Of course, as you have said, the disease has been effectively stamped out in this country, without having recourse to Pasteur's treatment?"; and you in answer to that question said, "Certainly." On reading it over it seemed to me that there must have been a misunderstanding, either on the part of Dr. Wilson, in putting the question, or upon your part in assenting to it; because it appears to imply either that it had been claimed by somebody that the application of the Pasteurian treatment to human beings might be expected to have the effect of exterminating rabies in dogs; or alternatively it appears to imply that the Pasteurian treatment was never applied to people in this country who were bitten by rabid dogs. I want to know from you now whether you are prepared to answer the question "Certainly," taking it in either of those senses?—When I said "Certainly," I meant that the Pasteur treatment had nothing to do with the stamping out of rabies in dogs.

12165. But it is qualified by the expression "in this country"?—But rabies is essentially a disease of the dog, and the treatment of the men who are the victims of the dogs' bites by Pasteur's treatment will not affect the disease amongst the dogs. That is why I said "Certainly."

12166. But have you ever heard it suggested that the Pasteurian treatment, whether it is good or bad, can have any influence upon the spread of rabies or the continuance of it among dogs?—No.

12167. You would not assent to the statement that in this country people have not derived any benefit from the Pasteurian treatment?—No.

12168. Do you believe, on the contrary, that some of them have derived benefit?—Certainly.

12169. Then I want to direct your attention to a question or two on the preceding page, beginning at Question No. 11914. These questions were with regard to the reason why, in the statistics purporting to set forth the failures of the Pasteurian treatment, those cases were excluded in which the disease developed within fifteen days after the treatment had been completed; and you have given the reason which to you appears to justify the exclusion of these cases in answer to question 11917. But the question I want to ask you is this: Are the available statistics greatly affected, supposing these cases are included among the failures; or could you give us any evidence showing what the percentage is in which the disease develops in persons subjected to the Pasteurian treatment, excluding no cases at all?—If these cases were not excluded the mortality would be about doubled, or a little more than doubled, so far as I can judge. I can only remember the figures in round numbers for one Institute, but that is a large institute, and included about 30,000 cases. The mortality given in the usual way, excluding persons who have died within fifteen days of the treatment, was about 0.45 per cent., and, taking the total mortality, it was about 1 per cent. (See note after Question 12173 below.)

12170. As compared with the mortality among non-treated persons?—In the figures that I collected and gave in my evidence that mortality would appear to be about 17 per cent. I can put in the exact figures, of course, if it is wished, but that is as nearly as I can remember.

12171. I think it would be as well to calculate out the figures showing what the calculated mortality for bitten persons was?—Not for every institute, I trust.

12172. The larger the number of statistics you put in, the more convincing it will be. Probably 30,000 cases would suffice for the one institute?—Yes, I can put my hand on 30,000 cases from one institute; but to put in the total statistics for 150,000 cases would be a great labour.

12173. I think we would be content with 30,000?—From 1890 to 1905 28,033 persons underwent Pasteur anti-rabies inoculation at the Buda Pesth Pasteur Institute. (Report of the Institute, 1905, by Dr. August v. Szekeley, director Centraebl. f. Bakt. Part 1. Referate vol. 40, p. 34, 1907.) Of these 159 died during or within 15 days after the treatment and 129 subsequently. The total mortality was 1.02 per cent. and the mortality, excluding the 159 cases from the statistics, 0.46 per cent.

12174. (*Sir Mackenzie Chalmers.*) Have you statistics of the Kasauli Institute?—Not with me; but they are given in the report of the Sanitary Commissioner for India year by year.

12175. They show the number of people treated, and the number of failures, but they do not show at what date the treatment was commenced?—No, they are not at all full in that Report.

12176. (*Sir William Collins.*) The evidence which you have been so good as to give the Commission has dealt mainly with the causation and control of infectious and infective diseases, has it not? So far as our knowledge and our power in regard to them have, in your opinion, been the result of experiments upon living animals?—Yes.

12177. Do you think that in the evidence which you have given to the Commission you have had due regard to what might be called the failures as well as to the successes of bacteriology?—I have not been concerned with the failures of bacteriology. There are failures in every form of scientific inquiry.

12178. For instance, I notice on page 1 of your *précis* you tell us that Pasteur's methods have led to the discovery of the causation of most infectious diseases to which man is liable?—I think that is so.

12179. Would you tell me, for instance, in the case of scarlet fever, have we identified the cause of it?—No.

12180. Or of measles?—No.

12181. Typhus?—No.

12182. Small-pox?—No.

12183. Chicken-pox?—No.

12184. Whooping cough?—Yes, that is probably correct.

12185. Would you name the organism?—No. I will name the authors—Bordet and Gengou.

12186. Are they the only experimenters who claim to have identified an organism as the cause of whooping cough?—I should think not.

12187. Do you regard their organism as established?—No, not as yet, but as very probable.

12188. Influenza?—Yes.

12189. Do you think that is established?—I think that is established.

12190. Would you name the author who has identified the true cause of influenza?—Pfeiffer.

12191. Have other authors claimed to have established other organisms as the cause of influenza?—No doubt.

12192. Mumps?—No, I think not.

12193. You would, I suppose, hardly have the Commission believe that sanitary science did not exist before the dawn of bacteriology?—No.

12194. You would hardly put aside as worthless the work of Chadwick, and Farr, and Simpson, and Radcliffe, and Dr. Kay, and Southwood Smith, and others?—No.

12195. Have there been means of stamping out or reducing mortality from diseases whose cause has not been identified as a particular organism?—Yes.

12196. Such as typhus?—Rabies.

12197. Typhus?—Small-pox.

12198. Do you agree that typhus is one of them?—Yes.

12199. And cattle plague, for instance; was that successfully dealt with before the identification of a par-

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

17 July 1907.

ticular organism as its cause?—No organism has yet been identified as the cause of rinderpest, I presume you mean?

12200. You would dispute any contention to the contrary?—Yes.

12201. And I think you intimated, if you did not actually state, that puerperal fever, by the reforms introduced by Semelweiss, was dealt with satisfactorily as regards its prevention before the identification of any particular organism as its cause?—I endeavored to point out that it was not dealt with satisfactorily, because persons would not believe in its infectivity until they had evidence of a specific cause.

12202. Was it not claimed in Vienna so long ago as the sixties of last century that by the adoption of Semelweiss's views the mortality from puerperal fever had been reduced, if not abolished, in lying-in institutions?—Semelweiss was practically persecuted in Vienna, and driven from his post, and died in a lunatic asylum, from suicide, I believe.

12203. Quite true; and a monument in recent years has been erected to his memory in Buda Pesth?—I think so.

12204. But if you consulted a letter written by himself to the "Medical Times Gazette" in 1861, you will find that there were those who recognised the truth of his doctrine even in Austria during his lifetime?—No doubt.

12205. And before the identification of an organism as the cause of puerperal fever?—Certainly.

12206. Now as regards tubercle, was it not at one time contended by the Medical Department of the Privy Council that Dr. Burdon Sanderson had established the cause of tubercle? You quoted several authors, such as Klencke and Cohnheim, but I do not see a reference to Sir John Burdon Sanderson?—I think, if I remember rightly, that Dr. Sanderson's (as he was then) observations were in the direction of showing that tubercle was not a specific disease.

12207. That it was due to what he called the common septic ferment?—Yes. But Sir John Burdon Sanderson was mistaken, and, of course, he fully realised that later.

12208. And did not Sir John Simon, in reporting his researches to the Privy Council, state in regard to these matters that he thought they might "now be taken as settled"?—That I do not know; but if so, Sir John Simon was also mistaken.

12209. You know Koch's work on the cure of consumption?—Do you mean on the introduction of tuberculin inoculations about 15 years ago?

12210. It was a work entitled "The Cure of Consumption," translated and published in this country in 1890?—I am not familiar with that pamphlet, but I was in London at the time when Koch's treatment was being extensively applied in some of the London hospitals.

12211. It was claimed in that work that "Phthisis in the early stages can be cured with certainty by this remedy"—that is, tuberculin. Is that established?—No, that is wrong, I imagine.

12212. Is tuberculin recognised as a cure for consumption?—The revival of tuberculin as a means of treatment has occurred within recent years, and I believe is giving beneficial results under modified conditions with regard to dosage.

12213. Do you remember Koch's last statement when in this country in regard to the prevention of consumption?—Koch has made a good many statements.

12214. Did he not rather advocate what might be called the sanitary mode of prevention rather than any method of inoculation?—I think prevention is always better than cure.

12215. But was the prevention to be by the wholesale inoculation of tuberculin or by the rooting out of insanitary dwellings, in Koch's opinion?—By preventing infection by all means.

12216. The passage to which I was referring is "That above all other considerations he placed 'the domestic conditions under which the poor everywhere, but especially in great cities, have to live. It is,' he said, 'the overcrowded dwellings of the poor that we have to regard as the real breeding places of tuberculosis; it is out of them that the disease always crops up anew, and it is to the abolition of these conditions that we must first and foremost direct our attention if we wish to attack the evil at its root, and to wage war against it with effective weapons'"?—I think that is quite sound.

12217. That was in 1901; I think it was his last visit to London. I notice also in this work of Koch's on the cure of consumption that he makes this rather remarkable statement: "As regards the effect of the remedy" (tuberculin) "on human beings, it was evident at the very beginning of the experiments, that in one very important point the effect of the remedy on man is entirely different from that on the guinea pig, which is the animal usually experimented upon," and he goes on to say: "Here, again, is a fresh and conclusive proof of that most important rule for all experimentalists, though an experiment on an animal gives no certain indication of the result of the same experiment upon a human being"?—I think that is true—"no certain indication."

12218. You would agree with that opinion?—I agree with "no certain indication."

12219. Do you agree with the opinion of Koch in regard to the non-communicability of the tubercle of animals to man?—No.

12220. Did he claim to have established that as the result of experiments upon animals?—I do not see how he could establish the non-communicability of bovine tubercle to man by experiments on animals.

12221. Did he claim that the tubercle of animals could not be conveyed to man?—It was his opinion that it was anyhow an insignificant way by which human beings become infected with tubercle.

12222. Has that been disproved?—I think it has been disproved by the Royal Commissions on Tuberculosis both in England and in Germany, and by other individual workers.

12223. Has that been the result of experiments on animals?—Yes.

12224. Then the disproof has been the result of experiments on animals, in your opinion?—Experiments upon animals have been necessary to obtain data for coming to that conclusion.

12225. Did not Koch claim that it was from experiments on animals that he got the data necessary to come to his, in your opinion, erroneous conclusion?—I do not think so.

12226. Did he not use experiments upon animals in the course of his investigations?—Certainly.

12227. Have you looked into the statistics of tetanus as to whether the death rate is going up or down?—No.

12228. Do you remember Kanthack's paper with regard to tetanus; did he not collect some cases?—I do not remember it.

12229. I think you spoke in one place of the cause of syphilis having been established by experiments on animals?—Did I?

12230. Yes, on page 13 of your *précis*?—I do not think it amounts quite to the statement that you have put in my mouth.

12231. I am very anxious that you should make your own statement, and if I have put one into your mouth I apologise for having done so. Will you make your own statement? You speak of "many cases in which bacteriological diagnosis of a disease" has been arrived at by experiments on animals, and in that category you mentioned syphilis?—Yes.

12232. I was under the impression that you implied that syphilis could be diagnosed by bacteriological investigation upon animals. If I am wrong in that contention, will you be so good as to correct me?—You are quite wrong.

12233. Then, perhaps, you will state what is your contention?—The contention in that statement is that syphilis can be diagnosed by the recognition of the spirochœta pallida.

12234. Has not the spirochœta pallida been claimed as the cause of syphilis?—Yes.

12235. By Schaudin?—Schaudin himself did not claim it as the cause. He was the discoverer of it in syphilitic material. His partner, Professor Hoffman, suggested it as the cause. It has been extensively investigated by hundreds of persons in every country during the last two or three years, and has been found

to be almost invariably associated with syphilitic lesions of different kinds.

12236. Then am I right in thinking that, if not by you and possibly not by Schaudin, at any rate, by some observers, the spirochœta pallida has been claimed as the cause of syphilis?—By hundreds. And strength has been given to that claim by the fact that material containing the spirochœta pallida can be inoculated into apes and reproduce the disease.

12237. Up to a few years ago was not Lustgarten's bacillus claimed as the cause of syphilis?—Lustgarten claimed the bacillus as being the cause of syphilis, but he was mistaken and was speedily shown to be mistaken.

12238. For many years Lustgarten's bacillus was mentioned in text books as the cause of syphilis, was it not?—That may be so.

12239. You remember Mr. Watson Cheyne's remark in regard to that, in which he said, "But lately Alvarez and Favel state that they have found bacilli in the smegma taken from the healthy prepuce which stain almost in precisely the same manner as Lustgarten's bacillus and as the tubercle bacillus"?—That was one of the observations which showed that Lustgarten's contentions were not justified.

12240. Do you agree with Mr. Watson Cheyne in that statement?—Yes.

12241. You have given the figures for deaths from hydrophobia in Paris in your *précis*. Have you looked into the statistics for this country?—No, I have not looked into the statistics for this country. So far as I know, anti-rabic inoculation has never been performed in this country.

12242. But the Registrar-General for England and Wales publishes the figures of the deaths from hydrophobia?—I believe so.

12243. I have them before me from 1886 to 1905 (the same years that you give for Paris). I find (page 48), beginning with 1886, there were 2, 2, 4, 8, 4, 1, 1, 1, 2, 3, 1, 0, 1; and then since 1899, none—that is, of females—and of males for the same years (page 34), 24, 27, 10, 22, 4, 6, 5, 3, 11, 17, 7, 6, 1, 0, 0, 0, 2, 0, 0, 0. That makes 175 in the same years that you have given the figures for Paris as 124, I think. One is comparing England and Wales, of course, with Paris. Has it occurred to you to make any remark upon those figures?—I cannot see that there is any connection between those two sets of figures.

12244. Are you able to give any suggestion as to the reason why there has been hardly any fatal hydrophobia or rabies in man in this country since 1899?—I believe there has been no rabies in this country since about that time.

12245. Will you give us your opinion as to why there has been no rabies since 1899?—Because of Mr. Long's Bill to muzzle the dogs.

12246. The result of muzzling the dogs has been the abolition of rabies in dogs and the absence of hydrophobia in human beings?—Yes.

12247. I thought that would be the explanation that you would give me.

12248. (*Colonel Lockwood.*) And the restrictions on importation?—Yes, the quarantine restrictions.

12249. (*Sir William Collins.*) Are similar methods not practised in France?—No, people interested in rabies in France have urged upon the French Government to employ some such means, and have pointed to England as the great example. In Germany muzzling orders and the destruction of stray dogs is carefully carried out, and one way in which they have diminished the number of dogs of doubtful ownership was by doubling the dog tax.

12250. At any rate, in this respect this country seems to have the advantage of France?—It has the advantage of France in this respect.

12251. (*Sir John McFadyean.*) Has not Great Britain in this connection got an immense advantage through being an island? Is it possible to establish a quarantine for dogs all round the French frontier, which would be absolutely essential to securing the result we have in this country, would it not?—Yes, it would.

12252. (*Sir William Collins.*) Now, as regards the curative value of diphtheria antitoxin, I see you have given various percentages of case mortality of diphtheria apart from the use of antitoxin?—The case mortality from antitoxin varies much in different years and in different epidemics.

12253. On page 20 of your *précis* I see you give 80 per cent. in one hospital in Paris, 60 per cent. in another, and then on page 21 you give 21.6 per cent. in 1892 in London, and, as you say, there are great variations in the case mortality apart from antitoxin?—Yes, quite so.

12254. On page 23 of your *précis* you give some Russian statistics—cases treated by antitoxin, mortality 14.6 per cent; cases not so treated, 34.1 per cent. Have you looked into the figures of cases treated with and without antitoxin in London?—I do not know where to get any reliable figures that coincide in time for London. I doubt whether there are any available.

12255. The statistical report of the Metropolitan Asylums Board purports to supply them?—Coincident in time?

12256. Year by year. On page 309 of their Medical Supplement for 1906 I see cases treated with antitoxin, mortality 10.4 per cent.; cases not so treated, mortality 1.5 per cent. I thought you would desire to offer some explanation of that?—I am not aware of those figures. I have no doubt that there is a satisfactory explanation of them consistent with what I have put forth.

12257. You have given a statement on pages 23 and 24 of your *précis* as to the caution that is necessary in dealing with mortality statistics of diphtheria. Has the mode of diagnosing diphtheria changed largely since the introduction of the antitoxin treatment?—I imagine that a considerable number of cases are now diagnosed with greater certainty by bacteriological diagnosis of swabs from the throat.

12258. Prior to 1895 were any cases diagnosed in that way?—Yes.

12259. Will you give me the year prior to which no such case was diagnosed in that way?—Say 1883.

12260. When was the treatment by antitoxin and the diagnosis of it by finding the bacillus commenced?—The discovery of the bacillus was in 1882; it was established in 1882 and Roux's cases were treated in 1894.

12261. When would you say that the bacteriological mode of diagnosis was largely adopted?—As a routine practice in England about 1890—somewhere between 1890 and 1892, I imagine.

12262. And the antitoxin treatment commenced and became general in what year?—It commenced in this country about the middle of 1895.

12263. Has the introduction and the large use of bacteriological diagnosis been the means of bringing, as it were, under review a large number of cases which, prior to the use of the bacteriological diagnosis, were not called diphtheria?—I have indicated in my evidence that that is extremely probable.

12264. And that has to be taken into account in estimating the mortality?—Yes.

12265. Both case mortality and mortality per population, or not?—In estimating the case mortality.

12266. The case mortality only. Now, according to the figures published by the Metropolitan Asylums Board, the case mortality in 1888 was 59.3 per cent. for diphtheria, and then in the following years it fell to 40.7, 33.5, 30.6, 29.3, 30.4, 29.3. Those years would be prior to the antitoxin treatment, would they not?—Which was the last year?

12267. 1894—29.3?—Yes.

12268. There was a fall in the case mortality prior to the antitoxin treatment?—According to those figures, yes.

12269. And since 1894 the mortality has further declined from 22.8 down to 8.8 in 1906. I understand the point made by you, on page 23 of your *précis*, is, that if the cases of diphtheria are largely added to by the superaddition of a number of mild cases recognised by bacteriological diagnosis, that would have the effect of reducing the case mortality?—It would have that effect.

12270. Are you able to estimate the extent to which that cause is operative?—No.

12271. You yourself have written upon snake venom, have you not, in Clifford Allbut's "System of Medicine"?—Yes.

12272. I see you state there, "The mortality in persons bitten by the larger snakes of India and South America would not, from the scanty records available, appear to be more than 30 per cent."?—I may have said so

Mr. C. J. Martin, M.B., D.Sc F.R.S. 17 July 1907.

12273. The mortality in persons bitten?—May I have the date; there are two editions.

12274. 1907 is the one this has been extracted from?—That is the last edition. I may have made that statement.

12275. You also, I think, in this paper, discuss the method advocated by Sir Lauder Brunton and Major Rogers?—I have no doubt.

12276. I find this passage, "Washing the punctures with any kind of solution is of course futile. Wall also considers that the application of any disinfecting agent to an incision through the wounds is almost useless; he found that such a method sometimes succeeded after the injection of the poison with a syringe, but was without avail after the natural bite of a snake. The same difficulty will be met with in the method lately advocated by Sir L. Brunton, Sir J. Fayrer, and Major Rogers, in which it is advised that an incision be made over the punctures with a lancet-shaped blade and crystals of permanganate of potash then be rubbed in. Major Rogers found this method successful in the case of cats, but in these experiments he knew accurately the direction taken by the point of the needle. In practice we find that it will only be by chance that the permanganate reaches the poison, which may be placed deeply in the areolar tissue and at some distance from the punctures." That was your opinion in 1907, I gather?—It is my opinion now.

12277. I thought you would probably give me that answer.

12278. (*Chairman.*) When you speak of the larger snakes in India and South America and the percentage of deaths, what do you include in the larger snakes, because some of the large snakes do not kill by biting?—No, the very large snakes are not poisonous.

12279. Do you include the cobra?—Yes.

12280. The rattlesnake?—Yes, and the fer de lance.

12281. The most deadly?—Yes.

12282. (*Sir William Collins.*) You think, then, that all this washing of punctures with any kind of solution is futile?—Yes.

12283. You attach some importance to the elastic ligature and to excision of the infected part?—Yes.

12284. Do you regard that as the only useful treatment that at present can be advocated?—No, I think you can get a certain amount of usefulness by the injection of antivenin—that is a serum.

12285. Do you agree that the difficulty with regard to that is to get antivenin, which is polyvalent?—Yes.

12286. Then as regards plague, you are a member of the Committee on Plague that is now engaged on its researches, are you not?—There is a Committee and a Commission.

12287. I am afraid I cannot discriminate; will you be so good as to discriminate between the Committee and the Commission?—The Committee is an Advisory Committee appointed by the Secretary of State for India, and the work has been done by a Commission.

12288. Is it a Royal Commission?—No, a Commission.

12289. Who appointed the Commission?—The Committee.

12290. The Commission has emanated from the Committee?—Yes, the Committee have placed their work in Commission. I was in the first instance, at the request of my colleagues on the Advisory Committee, in India for eight months organising things and starting the work, so that to that extent I was a member of the Commission as well as of the Committee.

12291. There was a previous Plague Commission, was there not, in 1901, which, I think, reported?—That was a Commission to take evidence. Ours is essentially a working Commission.

12292. Have you read the report of the previous Commission?—I have read most of it at some time or other. It is several large volumes.

12293. I notice that amongst their conclusions they state: "Plague has attacked persons who have undergone inoculation as many as four times in the course of two years previous to their attack," and, again, "as many as 8 per cent. of the inoculated population may suffer from plague, as was the case in Bulsar. Many varying influences have been at work in determining the rate of attack in different places, and it is impossible to give a numerical expression for the measures of protection against attack which inoculation confers"?—That was the opinion of the Indian Plague Commission from the early records of inoculation, I imagine.

12294. Six years ago?—Yes, it is a long time ago.

12295. I think you investigated, or had something to do with the investigation, with regard to certain untoward results which followed the use of Haffkine's vaccine at Malkowal?—There were certain questions of scientific fact and opinion concerning that accident, which were referred to the Lister Institute.

12296. As we have had the matter mentioned, and you yourself, I think, reported upon it for the Lister Institute, perhaps you will be so good as to state the result of your inquiries as to the source of contamination of tetanus, from which, I think, 19 persons died who were vaccinated with Haffkine's material?—The expression of opinion of the Institute was, as briefly as possible, in the following words: "That the probabilities are in favour of the view that the tetanus impurity was primarily in the fluid, but that they did not feel justified in asserting this as a proved fact in view of the possibility of contamination at Malkowal."

12297. Did the conclusions of the Institute coincide with those of the Commission?—I am not quite sure what the conclusions of the Commission were. I think they substantially coincided.

12298. I have before me a report entitled "East India (Punjab) Inquiry into Deaths from Tetanus" (Cd. No. 106), which states: "With reference to the findings of the Malkowal Commission, the Institute" (that is, your Institute, the Lister Institute) "were asked to report, among other matters (1) on the comparative efficacy of the standard and the new fluids as a protection against plague; (2) on the comparative liability of each fluid to contamination; (3) on the probable origin of the tetanus virus in the Malkowal cases. Their Report on these questions reached India early in December, 1904. They summarised their conclusions as follows:—(1) The Institute sees no reason to differ from the conclusions of the Commission that the new prophylactic is not less efficacious than the old. (2) The Institute is of opinion that in the hands of more or less unskilled workers it is easier to ensure freedom from contamination by Mr. Haffkine's 'standard method' of manufacturing plague vaccine than with the 'water-agar proces' as employed by him. (3) The Institute is in entire agreement with the Commission as to the value of 0.5 per cent. carbolic acid in restraining tetanus growth when added to plague prophylactic, and its experiments emphasise still further the importance of this addition in preventing the growth and toxin formation in a vaccine which might be liable to the possibility of contamination with the spores of tetanus. (4) The conclusions of the Institute coincide with those of the Commission that in all probability the tetanus was, at the time of the inoculation, in the fluid contained in the bottle, but that it is impossible to determine at what stage in its history or in what way bottle 53N became contaminated.'" Were those the conclusions that appeared over your signature?—Yes.

12299. Then the conclusions of the Institute apparently did coincide with those of the Commission?—I think, in drafting that report, I used the word "coincide" when I should not have done. I think the Commission went a little further. The conclusions of the Institute coincided with my view of the findings of the Commission, but, as was pointed out to me afterwards, the Commission had gone a little further than we had in their views.

12300. Do you think that the inoculation with Haffkine's vaccine or any other vaccine in India is having a valuable influence in checking the spread of plague?—Very valuable.

12301. Do the figures indicate that?—I think so.

12302. I have before me a memorandum of the Royal College of Physicians, in July, 1905, on Plague, in which they say: "The total number of recorded deaths from plague in India during 1896, the first year of the present epidemic, was 30,000. In many weeks of last year, 1904, the mortality amounted to over 30,000 a week, and the total mortality from the disease for that year was 1,040,000. This year 687,705 deaths from plague were recorded for the first four months. The

mortality from plague in India has become greater in each successive year for nine years, the year 1900 excepted; and since 1896 nearly four million persons have died of the disease." From recent replies in Parliament I gather that from September, 1906, to April, 1907, 5,326,000 deaths from plague occurred, and in April, 1907, there were 314,000. Has plague ever been more prevalent in India in the memory of man than it has been during the past year?—Not that I am aware of. In reply to a question by Sir Mackenzie Chalmers, last week, I was unable to agree that the evidence that some hundred or so inoculated persons under our control in India had not suffered from plague to any extent was of any value, on account of the small number; but I have since remembered that there was a very good observation made amongst all the sweepers of the whole City of Bombay, who were being utilised in connection with our Commission to gather in dead rats every morning, and the amount came to upwards of 5,000 a week, all of which were examined for plague by the Commission.

12303. (*Sir Mackenzie Chalmers.*) 5,000 dead rats, or sweepers?—5,000 dead rats. These men were under the control of the health authorities—the municipal officer of health—they were working to assist us. The figures there, I think, are large enough to be significant. There were 7,182 inoculated sweepers, and there were 418 uninoculated sweepers. The attacks of plague were as follows:—Amongst the 7,000 inoculated, 14; amongst the 4,000 uninoculated, 28. The deaths among the 7,000 inoculated were 13, and amongst the 4,000 uninoculated 26. In other words, the percentage of attacks among the uninoculated was 6.7, and among the inoculated 1.9.

12304. (*Sir William Collins.*) What paper are you quoting?—This is from the Report of the Plague Research Laboratory for the official year ending the 31st March, 1906.

12305. Were they all housed in the same way; because I saw some reference to sweepers being housed in certain quarters, in one of the official reports?—The sweepers are a low caste people; they always live by themselves. But not altogether for the whole of Bombay. In each quarter of the town there are certain streets where the sweepers live.

12306. Are there any living in mud huts?—Not in Bombay, I imagine.

12307. (*Chairman.*) The mortality among those attacked seems to have been about the same in each case?—Yes.

12308. 26 out of 28, and 13 out of 14?—Yes.

12309. (*Mr. Tomkinson.*) Are those percentages the percentages of those attacked inoculated or not inoculated?—Yes.

12310. Not the deaths of those attacked?—No.

12311. (*Sir William Church.*) To what should you attribute the fact that Semelweiss's teaching did not spread in Europe or Holmes' in America with regard to puerperal fever?—To the natural disability of man to assimilate a new idea.

12312. That is to say, they were unable to demonstrate the cause of the spread of the disease. It was a mere theory?—Yes.

12313. Until bacteriology enabled a definite cause to be demonstrated?—That is my opinion.

12314. Sir William Collins mentioned a number of diseases to which we are liable, and on which no light has yet been thrown by bacteriology as to their cause—mumps, typhoid, measles, chicken-pox, and various others; but are any of those diseases diseases which we share in common with other animals?—That has been one of the difficulties in ascertaining their cause. In most of those cases it is impossible to communicate them to animals and make an experiment.

12315. Therefore we have been unable to study them on animals?—Yes; I think that is largely the reason why we have proceeded such a short distance.

12316. I want to ask you one or two questions about diphtheria. First of all I want to know what is your definition of paralysis? You have been good enough to furnish us with a table showing the total number of cases of paralysis, some severe, and the number of fatal cases, in answer to Question 11736?—For the purposes of that table I imagine that the slightest interference with motive power in any part of the body is regarded as a case of diphtheritic paralysis.

12317. It would include then all cases of paralysis of the palate or of the eyes?—Yes.

12318. And also of the limbs?—Certainly, the slightest difficulty in swallowing will be called a case of diphtheritic paralysis.

12319. This includes everything?—Yes.

12320. You have no means of telling us whether the number of severe cases of paralysis has increased—cases in which the limbs are paralysed?—No; the figures are very small, you see, for severe paralysis; they would not be very significant.

12321. Then how was it, as you have been taking immense labour in collecting statistics with regard to the antitoxin treatment, that you were not acquainted with the information that Dr. Wilson gave us from Toronto?—I have no doubt that had I spent more time I could have made out a much stronger case. I could, anyhow, have given much larger numbers of figures. But Dr. Wilson quoted from a report in a provincial town in Canada, and I did not look in those places for it.

12322. You were not acquainted with it?—No, I was not acquainted with it.

12323. You are not any more acquainted than the Commission are with it; therefore you do not know whether it is exactly comparable?—No.

12324. Quite apart from the statistics, which I do not wish to go into, have you ever met with any doctor who has had a large experience of diphtheria before the introduction of antitoxin, and subsequently to the introduction of antitoxin, who has not thought it of value?—No, I have never met such an one.

12325. (*Colonel Lockwood.*) We were talking about muzzling being a preventive of the disease of rabies in England. Are you aware that in France, especially in the south, muzzling is largely used?—It may be used at the present time.

12326. It has been for ten years?—Has it?

12327. And is very strongly enforced, but rabies still exists very largely, does it not, in France?—I am unable to say offhand to what extent; it varies so much from year to year. It always occurs in epidemics. If you get one rabid dog you may get a hundred; they bite one another. And then it disappears almost entirely from the neighbourhood.

12328. But it does exist in France at the present time?—Yes, it certainly exists.

12329. In reference to the answers that you gave on the question of diphtheria, you are probably aware that the diagnosis of diphtheria in country districts is extremely loose?—I imagine it is not so efficient as it is in the Metropolitan Asylums Board.

12330. Are not the medical officers of health paid so much for every case of diphtheria that they detect? Perhaps you do not know?—I do not know whether they have a notification fee now or not. If so, it would be such a very small amount that I do not imagine that it would tempt even the most impecunious medical man to increase the rate. (*Note.*—Colonel Lockwood was presumably referring to the Medical practitioner and not to the Medical Officer of Health, and I answered the question in that sense.)

12331. You are aware of the very strong feeling existing in a large section of the public against the employment of experiments on living animals?—I am.

12332. To what would you attribute that feeling?—I think it is the natural instinct of a decent-minded man; and it has to be reasoned out of him.

12333. Do you attribute it entirely to sentiment?—I attribute it to the natural disinclination that any right-minded person has to inconvenience any animal unnecessarily.

12334. But do not the medical profession, for whom I have the greatest respect, equally share in that opinion?—I think the medical profession share equally in the sentiment which I have just expressed; but they understand the usefulness and the necessity for inconveniencing animals and utilising them for our own ends.

12335. You think that the reason why there is no repugnance, if that is the right expression to use, among the medical profession to experiment upon living animals is due to a wish to benefit human nature, and that their natural sentiment is not deadened by continual experimentation?—I think not at all, any more than the sympathy of a medical man for children

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

17 July 1907.

in general is any less fine because he has to cause pain to children in the ordinary course of his occupation.

12336. You have told us in your evidence how valuable you think these experiments have been to science. Do you consider that science has suffered at all since the regulations existing at the present time have been imposed?—I do not think materially. I think a certain number of people may have wasted some of their time in correspondence; but I think no material hindrance has been imposed.

12337. Or do you think that our scientific men are less advanced than their brethren on the continent in consequence of those regulations?—No.

12338. When you answered the question with regard to the kindness of scientific men abroad in welcoming their *confrères* in their laboratories, and that we did not allow them in ours, there are some cases, are there not, of foreigners practising in England, what we may call roughly vivisection?—I believe not at the present time.

12339. There have been?—Yes, there have been. I was referring to the recent action of the Home Office, within the last few months, in refusing a licence to foreigners who come to work in our laboratories.

12340. But that only refers to the last few months?—Only to the last few months.

12341. Do you think that there are any extra measures of protection to animals that would tend to allay the state of public opinion, which, I am sure, you dislike as much as anybody? Could you not suggest to us any measure that would tend to allay that alarm that some of the public feel, and which, to the medical profession would not be repugnant?—I am unable to suggest any offhand, but I will think over the matter, and if I have any fertile suggestion to make, I will make it when I have studied Mr. Coleridge's proposed Bill.

12342. Thank you. That would be very valuable to us all. You have witnessed a good many experiments yourself?—Yes, a very large number.

12343. And in all those experiments have you never witnessed any, what we should call cruelty?—No.

12344. Much suffering?—Not much suffering.

12345. And in England, where the experiments you have witnessed are under licence, has the anæsthesia always been complete?—Yes, always.

12346. And the law strictly carried out?—And the law strictly carried out.

12347. And the carrying out of that law assisted and aided by all present?—Yes.

12348. Have you ever witnessed any levity on the part of the students?—I have had no experience with experiments before students in this country.

12349. But I will take your general answer, that you have never seen any cruelty exhibited, and that under the Act anæsthesia has always been complete?—Yes.

12350. Now, in answer to Question 12056, you stated that you had performed experiments in New South Wales, where there was no vivisection Act, and at 12060, in Melbourne, where there was a certain amount of restriction on experiments on animals?—That is so.

12351. As far as regards the progress of science in those two places, do you think there was any difference?—None whatever. I can take no exception to the form of the licence which I held in Melbourne; I think it was only right and proper.

12352. You see my reason, naturally, for asking. You do not think that the regulations imposed in Melbourne have any deterrent effect upon the advance of science?—None whatever; they were not in the least irksome.

12353. They existed?—They existed.

12354. (*Dr. Wilson.*) Have you yourself had any experience in the treatment of diphtheria?—Not a great experience.

12355. But you have had some?—Yes.

12356. And do you still adhere to that view which you expressed so strongly at the last sitting of the Commission, that if a patient sickening for diphtheria receives an adequate dose of antitoxin the case will not prove fatal, no matter of what intensity the infection may be?—Most emphatically. And I would point out that when asked by Sir William Collins whether I could supply any data from the figures at Chicago to substantiate that view, I said that I was unable to do so; but I find on looking through my evidence that those figures had already been supplied. 8,000 cases of bacteriologically verified diphtheria treated with antitoxin by the Chicago Health Department between 1895 and 1905 were cited, in which the mortality of 608 cases treated on the first day was reduced to 0.32 per cent; and just above that table was given the experience of the Brook Hospital of the Metropolitan Asylums Board for the years 1897 to 1902, in which the mortality of all cases treated on the first day was during all those years nil.

12357. (*Sir William Collins.*) Does the first day mean that the bacillus has been found and the invasion of symptoms, but no membrane in the throat?—It means that the patient is taken into hospital within 24 hours of the discovery of the disease.

12358. What does the discovery of the disease consist of?—It may mean a sore throat, which is certified to by a doctor, but in the majority of cases it would be a bacteriological examination nowadays.

12359. But would there be a false membrane in any or many of the cases on the first day of the disease?—No.

12360. Scarcely any?—Very few.

12361. (*Dr. Wilson.*) You admit that there are great errors of diagnosis without a false membrane?—No, I do not admit that. I admit that there are great errors in the clinical diagnosis of diphtheria, but I do not think that the errors of bacteriological diagnosis amount to more than 10 per cent. By "bacteriological diagnosis" in this sense I mean the examination of the growth obtained from the throat on one occasion.

12362. (*Sir Mackenzie Chalmers.*) May I call your attention to the paragraph in Sir James Thornton's pamphlet, "The Principal Claims on behalf of Vivisection," about Pasteur's anti-rabic inoculations, and ask you whether you have any observations that you wish to make upon it?—(*After referring.*) No, I have really no observations to make upon it. I have no doubt that Professor Billroth and Professor von Frisch may have expressed that opinion in early days. The Pasteurian treatment was not very popular in Germany when it was first introduced, owing to a good many reasons.

12363. There is no date given to Professor Billroth's opinion?—No, but I do not think Professor Billroth would have expressed that opinion recently.

12364. Is there any known or authenticated case in which it has been shown that the anti-rabic inoculation has itself created hydrophobia?—I am not aware of any.

12365. In the case of experiments on animals is rabies ever produced by inoculation in an unbitten animal?—Do you mean that should one take the cord straight out of a rabic animal and inject it under the skin of another animal would it give him rabies?

12366. No; what I meant was this: If you take the actual inoculations used for human beings, do the inoculations used for human beings, if inoculated into an animal, produce rabies?—If the animal is treated as human beings are treated it does not get rabies.

12367. That has been tried and tested?—It was, of course, tried a large number of times before Pasteur ever attempted it upon mankind.

12368. Then with the intensity of the treatment gradually increasing, does the same conclusion apply?—Yes.

12369. I was asking the question in reference to the fact that there certainly has been a fear that by undergoing the Pasteur treatment people may contract rabies?—I think that fear is unfounded. I gather that you wish to know whether there is a possibility, however remote, that by undergoing the Pasteur treatment, especially in its intensified form, a person might get hydrophobia who had not been infected by a dog?

12370. Yes?—There is a possibility, but it is extremely remote.

12371. (*Dr. Gaskell.*) Is it not the fact that the intensified form of treatment has been practically given up?—No; on the contrary, the intensified form of treatment is much more generally used now than it used to be, especially in Russia; they have had more confidence, and have realised more and more that the danger which Sir Mackenzie Chalmers has referred to is less and less.

12372. (*Sir Mackenzie Chalmers.*) Should you have any hesitation yourself in recommending anyone who

had been bitten to undergo the treatment?—None whatever.

12373. (*Mr. Ram.*) May I ask you one question with regard to what you said about the use of tuberculin? You said, as I gathered, that it was used, that doubts were cast upon it as to whether it was effective, and now there has been an increase in its use, with a modification of the dose?—That is so.

12374. What led to the re-introduction of it, or the re-use of it?—It was due to methods of ascertaining the action of tuberculin which were discovered by Wright, owing to which he found that the effect of a dose of 1-1000th of what used to be given in the early days was equally efficacious, and that the large doses were rather detrimental.

12375. Is Professor Wright now using it largely?—Extensively; nearly all the hospitals in London seem to me to be using it.

12376. Have you had any experience yourself of the results from its use?—My opinion on that would not be valuable, because I have not followed the cases. I have seen a series of cases one day and another series of cases another day. That is a question for the clinician.

Mr. C. J. Martin, M.B., D.Sc., F.R.S.

17 July 1907.

12377. Is it now claimed by Professor Wright that an absolute cure can be effected after there is undoubted tubercle by this treatment?—In the case of some forms of tubercle I believe that Professor Wright holds that opinion strongly.

12378. I think one of the witnesses told us it was being used in the case of tubercle in the bladder, which cannot, of course, be got at. Do you know any such case as that?—Yes, I have seen several cases of tuberculosis of the bladder and urinary apparatus.

12379. Treated in this method?—Treated in this method.

12380. Have you ever known of any case which has been believed to be an absolute cure?—Yes, but whether it was entirely due to tuberculin I am unable to say. I am not in a position to say. It can only be judged by large figures.

12381. (*Sir William Collins.*) Do you assert of your own knowledge that tuberculin cures consumption?—I have not, yet.

12382. I ask: Do you assert of your own knowledge that tuberculin cures consumption?—I am unable to assert that. I think, like all things in medicine, there are limitations to almost all our endeavours.

Mr. Dudley Wilmot Buxton, M.D., B.S., M.R.C.P., called in; and Examined.

12383. (*Chairman.*) You are a Doctor of Medicine and Past President of the Society of Anæsthetists?—I am.

12384. And you are Consulting Anæsthetist to the National Hospital for Paralysis and Epilepsy in Queen Square?—Yes.

12385. And you are Anæsthetist and Lecturer on Anæsthetics in University College Hospital?—I am.

12386. You have had a very large experience in the study and administration of anæsthetics?—Yes, very large.

12387. Anæsthetics, I suppose, were already used when you began your studies?—Yes.

12388. But since then it has been necessary to study them very carefully, and in the course of that study to make use of experiments upon animals?—That is so.

12389. We have had a good deal of controversial evidence as to the amount of sensation to pain which there is in animals under certain circumstances, under certain classes of anæsthetics, and under certain strengths of dose in application, and we should be very glad of your assistance in giving us information on those points, if you will. I think in your *précis*, which you have kindly sent us, you go very shortly and clearly into these matters. You say that anæsthesia is marked by progressive effects divided into degrees of narcosis upon the nervous system?—Yes.

12390. Will you explain that to us in your own way, especially with reference to the stages at which sensation of pain is lost, and more particularly with regard to the symptoms which occur during narcosis, and explain how far those may be ascertained to be symptomatic of pain or not?—Sensation in the first degree is *ab initio* deadened; in the second degree it is materially lessened; and in the third degree there is absolutely no sensation of pain. In the first degree I should say the sensation was very much lessened, in the second degree still more lessened, and in the third degree and after absolutely lost.

12391. How do you define the three degrees?—The degrees are roughly defined in this way. The first degree is generally from the commencement of the inhalation until the loss of conscious, voluntary movement; in the second degree there is movement, but it is not controlled by the higher perceptive centres.

12392. Is there sensation to pain in both those degrees?—There is some sensation to pain in the first degree, and less, but still some, in the second. I am now speaking of the induction period. Then the third degree is marked by the loss of all movement. The only movements which can obtain at the end of the second degree (all the degrees verge into one another) and in the third degree, are due to reflex excitation, and are not in any way connected with the higher perceptive centres.

12393. Are they accompanied by any sensation of pain?—Absolutely none.

Mr. D. W. Buxton, M.D. B.S., M.R.C.P

12394. Is that third degree what is sometimes called surgical anæsthesia?—Yes.

12395. Does that denote the amount of anæsthesia which any surgeon would insist upon in performing a serious painful operation?—Yes.

12396. To take a very familiar example, if you were administering an anæsthetic to a patient who was going to have a tooth extracted, would you go to the second degree or the third degree?—To the third.

12397. Whatever anæsthetic you are using, I suppose the third degree would have to be reached?—That is so. It is more difficult to discriminate the degrees under nitrous oxide (or laughing gas) than it is with chloroform, because the whole thing is so quick.

12398. But that is what you aim at?—You aim at complete anæsthesia, the third degree.

12399. You do not signal to the operator that he can begin until you consider that you have arrived at that condition?—That is so.

12400. Do you say that third degree would affect even the reflex movements?—Some of the reflex movements will persist, but not the superficial ones.

12401. Would you give us a precise definition of what you include in reflex movements. We have had the phrase used very often, but I do not know that anyone has precisely defined it?—A reflex movement, as I understand it, is a movement which is associated with stimulation of the nerve, the nerve travelling from the periphery, from the skin or the mucous membrane, to the spinal cord.

12402. You call that the afferent nerve?—Yes. It thus communicates with the centre of the spinal cord and then by an efferent, along an efferent nerve, it communicates with the muscle and produces contraction. In the chain of communication the higher perceptive centres are not included.

12403. You mean that that reflex movement travels from a nerve, along a nerve to the spinal cord and back again to the extreme of another nerve?—Yes, the muscular nerve.

12404. But it does not cause sensation to the spinal cord and the brain?—No.

12405. There is no sensation of pain in the brain?—No.

12406. It will produce movement although it does not produce pain?—That is so.

12407. Is that a common incident in operation under anæsthesia?—In certain operations, yes.

12408. Does the amount of movement depend upon the amount of pain which would be given by the operation?—No.

Mr. D. W. Buxton, M.D., B.S., M.R.C.P

17 July 1907

12409. Does it depend upon the locality of the operation?—It depends upon the locality entirely.

12410. And in some operations, I suppose, you may almost rely upon it that, however satisfactorily you have arrived at the third degree, there will be reflex movements?—That is so.

12411. And that to a certain extent you can judge beforehand whether there will be any?—Yes.

12412. We have had witnesses before us who have described movements which some of them have considered to be reflex movements, while others have suggested that they were movements indicating pain in the animal. Have you seen that evidence?—I think I have read most of the evidence; I have read all that has been published, at any rate.

12413. I am afraid that I have not gone through it in view of your evidence sufficiently to put specific cases to you, but perhaps some other members of the Commission may do. At any rate, what you have said to me is a general account of what reflex movement you may expect without necessarily indicating pain?—Yes.

12414. Are you able to ascertain with any certainty, and if so, will you tell us by what means, when that surgical anæsthesia has been reached?—The sign that one relies upon mainly is the loss of the eye reflex, the conjunctival reflex. If I touch my eye it blinks. In the third degree if I lift the lid and touch the eye there is no blinking, the normal conjunctival reflex.

12415. We have heard, for instance, of corneal reflexes being seen, and they have been referred to as being evidence that pain was felt. What do you say as to that?—I say that it is not true.

12416. You say that that is no indication that pain is felt?—I do.

12417. Have you seen that corneal reflex happen when there has been complete surgical anæsthesia?—Yes, certainly.

12418. Have you said all that you wish to say as to how you ascertain when the third degree is reached?—I gave you the salient sign by which it is usually recognised; one would depend not only upon that but upon various other signs. In watching the muscular system, for example, in most cases the muscular system will show rigidity at first, and having passed through that rigidity will become flaccid. Then one would know by that that the patient had gone through the second and passed into the third degree.

12419. Has a skilled anæsthetist any difficulty whatever in assuring himself that perfect insensibility to pain has been reached?—None at all.

12420. There are plenty of symptoms by which he can make himself quite sure?—Yes.

12421. Does the difficulty of arriving at that stage differ according to the kind of anæsthetic that is used, or do you ascertain it by the same means in the case of every anæsthetic?—No, it differs slightly. For example, in nitrous oxide one would judge by the breathing and not by the eye. In the case of chloroform and ether you judge mainly by the eye.

12422. (*Sir Mackenzie Chalmers.*) The eye of the patient or your own eye?—The eye of the patient.

12423. (*Chairman.*) Nitrous oxide is what we call laughing gas?—Yes.

12425. It is only given to human patients?—Yes. cept in special researches undertaken to elucidate the physiological action of that agent.

12425. It is only given to human pitients?—Yes.

12426. You have to watch also that respiration is not interfered with, have you not?—Yes, very closely.

12427. And the necessity for that differs very much according to the anæsthetic employed?—Yes.

12428. Which are the anæsthetics that most affect the respiration?—Chloroform and all the volatile anæsthetics.

12429. Is it always safe to use chloroform as an anæsthetic?—It depends upon the method which you adopt. In many cases it is not at all safe. If you adopt a regulating method, and know the percentage and the danger of using a high percentage of vapour—if you can keep your percentage of vapour below 2 per cent., you may give chloroform with impunity. If you give above 2 per cent. or give it by a method which does not enable you to regulate your percentage, you are treading upon dangerous ground.

12430. And you can mix chloroform with something else, I suppose, which will diminish the danger to respiration?—That is one way of getting a lower percentage.

12431. I think there has been some confusion in some of the evidence before us as to the use of the term light anæsthesia. It has been spoken of by some witnesses—I do not think by professional witnesses, but others—as if it meant something less than complete anæsthesia. Would you explain what the term means as employed by skilled workers?—We mean by light anæsthesia that the patient has been put through the third degree, has been completely anæsthetised, and then the depth of the anæsthesia has been lessened, so that he has been absolutely anæsthetised, and then we find that by giving a smaller quantity later on he remains absolutely anæsthetised and yet he is actually perhaps in the second degree of anæsthesia for a long operation. It is extremely important in long operations to limit the amount of anæsthetic that is given. Light anæsthesia has, of course, to be clearly distinguished from incomplete anæsthesia, where the patient has never been completely anæsthetised. In one case you have the blood at a certain degree of saturation; in the other case you have an irregular distribution of chloroform or other anæsthetic, and the patient has never been completely anæsthetised; he is always hovering between consciousness and unconsciousness.

12432. But in all operations do I rightly understand that if you are to avoid pain you must begin, at any rate, by bringing the patient to the state of what you call surgical anæsthesia?—Yes, that is so.

12433. If it is a long operation, I understand that you rather lighten the amount of anæsthesia as compared with what you would do if it was a short operation?—That is my meaning.

12434. And when it is so lightened under those circumstances, it is your business as an anæsthetist to see that it is never reduced below the condition in which the patient is free from pain?—Yes.

12435. And can that be done consistently with what you have described as light anæsthesia?—Absolutely.

12436. There is no doubt about it?—None at all.

12437. If you spoke of incomplete anæsthesia, I suppose it would mean that the patient was not necessarily free from pain?—Yes.

12438. You use the terms complete and incomplete with reference to pain?—Yes.

12439. Is there any difference, and, if so, will you explain it to us, in the method of operation of anæsthetics upon man and upon the lower animals?—None.

12440. Do you note their condition of insensibility and the degree of it in the same way with animals as you would with man?—Always.

12441. And are the dangers of particular anæsthetics the same with animals, or do they differ according to different animals?—I should say that the danger was practically the same. Animals perhaps die more frequently because they may not have been so carefully watched.

12442. That is to say, they may not have been so carefully watched as regards the amount of stress put upon them?—Yes, the amount of dosage employed.

12443. But if they die of excessive anæsthesia, that of course does not involve pain?—No.

12444. It may involve death, but not pain?—That is so; it is a negation of pain.

12445. Are animals subject to the same stress upon respiration as mankind are?—Yes.

12446. And do they die in the same way that human beings would if they had too much anæsthetic?—Yes.

12447. Will you tell us what are the general anæsthetics that are used in surgical practice?—Nitrous oxide, chloroform, and ether are very common. Chloride of methyl is used occasionally, chloride of ethyl more frequently; bromide of ethyl has been used, and scopolamine; and for local anæsthesia strovaine, eucaine, cocaine, and others of that nature.

12448. Morphin?—Morphin is seldom used in the ordinary sense of an anæsthetic by itself. It has been used largely with chloroform and with ether, but it is not very commonly used now owing to its action upon the respiratory centres. In working with a volatile anæsthetic you limit within a short time the effect of

your drug. Having once injected your morphin, you lose control of the action of your drug, and its action may go on, and your patient may succumb; you have no means of preventing it. You can remove your chloroform; you cannot remove your morphin.

12449. Are morphia and morphin the same?—Yes.

12450. Are morphin and chloroform used together?—They have been used together; they are less used now than formerly.

12451. And chloroform and ether are used together?—Yes, they are, as a mixture. And the A.C.E. mixture is used, which was invented by Harley. Then alcohol and chloroform, the mixture 1 in 10, invented by Professor Schäfer, has been recently used, and a mixture of chloroform and ether which has also been introduced is largely used, and a very large number of mixtures containing different proportions of ether and chloroform. Petroleum ether was used in a mixture or solution with sulphuric ether and chloroform some years ago. The number of mixtures is very large.

12452. Are these mixtures that you make use of governed by the length of the operation or the particular condition of the patient, or the particular choice and fancy of the operator?—They are largely governed, I think, by the choice of the anæsthetist. He would, of course, be regulated by the necessity of the operation and the patient; he would examine his patient, and he would be familiar with the requirements of the operation, and he would make his choice upon that.

12453. Then, besides those anæsthetics which you have mentioned, are there other drugs which are not generally spoken of as anæsthetics, but are soporifics, which, however, will be anæsthetic in their operation if enough of them is used?—Yes.

12454. Is there any advantage in using a strong dose of an ordinary soporific instead of an anæsthetic?—None as a rule in surgery.

12455. You generally use an anæsthetic if you want to operate?—Practically always.

12456. There is no object in using a soporific?—None whatever.

12457. Have the use and the action of anæsthetics been ascertained largely by means of experiments upon living animals?—Certainly.

12458. By testing them upon animals?—Yes.

12459. I think you have already explained to us that if you apply too strong a dose to an animal you may kill it, but you kill it without pain?—Yes.

12460. Therefore, you are not so afraid of testing it strongly upon an animal as you would be, naturally, of testing it upon a human being?—That is so.

12461. (*Colonel Lockwood.*) Have you witnessed many experiments upon living animals under the Act?—A large number.

12462. Is the same care taken as to the degree of anæsthesia of which you have been speaking in the case of animals which are undergoing severe operations as in the case of human beings?—I should say certainly.

12463. And you invariably wait for the same degree of insensibility?—I always do.

12464. And the various precautions to insure that degree being reached which are used with reference to human beings you have always, so far as you are acquainted, seen used for animals?—Yes, you would adopt the same criteria.

12465. That you have always adopted?—Yes.

12466. That is to say, the anæsthesia has always been complete before these severe operations which are performed under licence are begun?—Certainly.

12467. And where, under the licence, the animal is required to be killed before recovery from anæsthesia takes place, that has always been carried out?—Yes, in my experience.

12468. I mean so far as your experience goes?—That is so.

12469. You have never witnessed anything to the contrary?—No.

12470. How many kinds of anæsthetics are used, or is it always the ordinary A.C.E. mixture that is used for animals?—No; it differs a great deal. Sometimes the A.C.E. is used, sometimes chloroform, sometimes ether.

12471. But always chloroform in some form or another?—Sometimes chloroform, sometimes ether.

12472. But always one of those two or the mixture?—Yes.

12473. Not opium, we will say?—Morphia has been used—not in my own experience.

12474. In your opinion is morphia a complete anæsthetic?—Quite.

12475. For severe operations?—Certainly.

12476. No pain would be present?—Not if you had a sufficient dose of it.

12477. Are you acquainted with the general provisions of the Act under which these experiments are carried out?—I am.

12478. Are you of opinion that they sufficiently guard animals from suffering?—Yes, I think that occasionally animals are unnecessarily killed.

12479. You mean under the provisions of the Act?—Yes.

12480. You think that they might safely be allowed to recover?—Certainly.

12481. That instead of adding extra precautions to those under the Act you would be in favour of relaxing some of them?—In that sense, certainly. I think that animals are sometimes extinguished when they might live long and have a happy life.

12482. You mean rather a happy life in the cause of science, not for their comfort?—Possibly for their own comfort.

12483. But you are talking, I presume, more of the scientific life?—Perhaps it is more a side issue, but I mean to say that in cases where an operation has been performed, it not being one to give the animal inconvenience afterwards, it seems a pity that it should be killed.

12484. Therefore, you are not prepared to assist us in any way by suggesting any further restrictions?—No.

12485. You think that the Act goes plenty far enough as regards the animals and the prevention of cruelty on the part of operators?—I think so. I think the well-being of the animals is quite safeguarded.

12486. You have never seen any cruelty in any work that you have witnessed?—Never.

12487. Nor have you seen an animal struggling or crying?—I have seen reflex movements. I have never seen conscious movements.

12488. (*Sir William Church.*) Have you had much experience in giving anæsthetics and seeing anæsthetics administered to animals other than man?—I have actually done it very many times to animals.

12489. We have been told by several witnesses that dogs are particularly difficult to keep under anæsthetics. Is that your experience?—Certainly not.

12490. There is no difficulty in keeping a dog for several hours under anæsthetics?—Not if you understand your business.

12491. We have also been told that it requires a very skilled anæsthetist to anæsthetise a dog. Is that so?—That would depend entirely upon the apparatus employed.

12492. Perhaps you would describe to the Commission the ordinary way in which a dog is anæsthetised for physiological purposes?—There, again, that must depend very largely upon the laboratory and upon what the purpose of the operation is. I should say that the most common method was by means of a Woulff bottle, allowing the air to pass over the surface of the chloroform.

12493. That would be a case in which the trachea is opened for a very prolonged experiment?—Yes.

12494. What is the ordinary way of anæsthetising a dog in a physiological laboratory?—By means of tow or lint with the anæsthetic poured upon it.

12495. Either by means of a mask, the animal being held under the mask, or by placing the dog in a basket with the anæsthetic?—Yes.

12496. And in your opinion is any special skill or knowledge required for anæsthetising a dog in order to produce anæsthesia?—No, I think not. Of course, an inexpert person may produce an overdose by giving too much. I do not think he is likely to err on the other side.

Mr. D. W. Burton, M.D., B.S., M.R.C.P.

17 July 1907.

12497. And in the case of those prolonged experiments in which it is necessary to administer an anæsthetic through a tracheotomy tube, do you think that there is any difficulty in regulating the dose of the anæsthetic?—None whatever.

12498. It is quite easy to regulate the dose of the anæsthetic in proportion to the air supplied to the animal?—Quite.

12499. Therefore, if the dose of anæsthetic was insufficient, the dose of air would be insufficient, and the animal would die?—That is so.

12500. That is your opinion?—That is my opinion.

12501. Have you any experience of administering morphia to dogs before you commence or as soon as you commence administering the chloroform, giving the two together?—I have no personal experience.

12502. Perhaps, then, you would not like to state before the Commission whether or not it is true that subsequent to the injection of morphia a lighter and less amount of chloroform is required?—I can certainly state that, because I have frequently employed morphia in the human subject before other drugs, such as chloroform or ether or scopolamine, and I have always found the amount of general anæsthetic required extremely small when morphia is given beforehand. The same, of course, would obtain in the case of the lower animals.

12503. Is it a common practice in human patients to administer a small dose of morphia subsequently to the chloroform?—Yes, it is very common.

12504. The purpose of it being what?—To keep the patient quiet and to prevent their having any subsequent pain, and to ensure sleep and rest.

12505. Just to keep them quiet?—Yes.

12506. Can you tell the Commission anything about the action of morphia upon dogs apart from chloroform?—I do not think, really, my evidence would be of much value upon the point.

12507. Have you any experience of administering opium, in the form of tincture of opium, to dogs?—No.

12508. You would not like to say what would be the effect of injecting a drachm of opium into the veins of a dog?—No.

12509. Would it be subject to pain?—No.

12510. Taking your division of the effects of chloroform into three degrees——?—I only got so far as the third; there are five degrees really.

12511. I think you said the first degree was until loss of control of voluntary movement?—Yes.

12512. The second degree was when the movements were not controlled voluntarily?—Yes.

12513. And the third degree was that of complete surgical anæsthesia?—Yes.

12514. In labour cases chloroform is frequently used, is it not?—Yes.

12515. Which degree of anæsthesia do you produce then?—The second, for alleviation of pain; not, of course, in a midwifery case necessitating a surgical operation.

12516. I am speaking of natural labour, of course, not labour in which surgical aid has to be rendered?—That would be the second degree. If any operation has to be performed it would be the third degree.

12517. We have heard a great deal of the value of different terms here which I think have been used without, perhaps, due consideration. You would consider incomplete anæsthesia any form in which voluntary movement remains?—Yes.

12518. But would you consider it a condition of incomplete anæsthesia in which uncontrolled movements occurred?—Oh, no.

12519. Is incomplete anæsthesia a term that is used often by anæsthetists?—Yes, I think so.

12520. And would it, in your mind, be equivalent to the term which has also been used before us of light anæsthesia?—No.

12521. It would be something less than light anæsthesia?—Yes, in a way it is quite a different thing. Light anæsthesia is complete anæsthesia; light narcosis is complete anæsthesia.

12522. You would include light anæsthesia under complete anæsthesia?—Yes.

12523. It has also been put before us by a witness here that, short of the abolition of the corneal reflex, you cannot have anæsthesia. Is that so, in your opinion?—I do not admit that.

12524. Is that belief held by any competent chloroformist?—I believe not.

12525. Reflex movements, which are of very different natures, can be called forth, can they not? Reflex movements of various sorts can be obtained in very different stages of anæsthesia?—That is so.

12526. That is to say, there are certain parts of the body which, when stimulated, produce reflex movements in what one might call a deep state of anæsthesia?—Certainly.

12527. That is in a state of anæsthesia so complete that all muscular action almost is lost?—All voluntary muscular action?

12528. I meant all voluntary muscular action?—Yes.

12529. Is so deep an anæsthesia as that a condition which is often called for in surgical operations on man—I mean, absolute abolition of all movement?—No, you cannot do that unless you kill your patient.

12530. But it is often done, is it not, in physiological operations upon animals for the sake of abolition of all movement?—If you have artificial respiration carried on, of course.

12531. Therefore, the fact that occasionally reflex movements may be seen in animals which are being operated upon by physiologists or research workers is no proof that they are not completely anæsthetic, although it is a proof that they are not in the profoundest condition of anæsthesia?—That is so.

12532. (*Sir William Collins.*) Do you hold a vivisection licence yourself?—Yes.

12533. Have you held it for long?—For a good many years.

12534. What form of licence is it?—The ordinary form of licence.

12535. You have no certificate?—No certificate.

12536. You hold it with a view to investigating the action of anæsthetics?—Quite so.

12537. And no pain would occur in any of your experiments?—None.

12538. Are there still some problems in connection with anæsthetics which require elucidation?—I am sorry to say there are.

12539. Should I be right in thinking that the discovery of anæsthetics was not due to experiments on animals?—The actual discovery of anæsthesia was not. Our knowledge of the precise action of anæsthesia is entirely due to such experiments.

12540. Is our knowledge of the precise action of anæsthesia complete to-day?—Not complete. Our knowledge of very few subjects is complete.

12541. Have you witnessed any surgical operation of any magnitude upon a human subject under morphia as the only anæsthetic?—I have never seen any.

12542. Would you advise it?—Certainly not.

12543. You have used, and other witnesses have used the terms, apparently discriminating between them, of light anæsthesia, incomplete anæsthesia, and complete anæsthesia?—Yes.

12544. Would it be troubling you too much if I asked you to give us a definition of each of those three terms now?—Complete anæsthesia is that degree of narcosis where there is no pain felt. Incomplete anæsthesia is that degree of narcosis where pain is felt. Light anæsthesia is complete anæsthesia. You have complete anæsthesia in profound narcosis; or you may have complete anæsthesia with light narcosis. That is as near as I can get to a definition.

12545. So far as I can gather, the appeal in each case is to pain as the differentia?—Yes.

12546. Can you suggest any other test, not subjective, but objective, by which the three varieties could be discriminated?—I have already mentioned various ocular phenomena that guide one as to whether there is pain or not pain, which would direct the anæsthetist's attention to the presence or absence of pain—the ocular phenomena and purposive movement.

12547. Is the conjunctival reflex present in complete anæsthesia?—Conjunctival reflex is absent. It may be very sluggish in very light anæsthesia; it is not brisk. In incomplete anæsthesia it will be fairly brisk.

12548. Then there is a stage of anæsthesia, I understand from you, in which the corneal reflex is present, and even brisk, and yet there is insensibility to pain?—By the corneal reflex, do I rightly understand you to mean the conjunctival reflex?

12549. I meant to use the conjunctival reflex all through, if you make a distinction?—I do.

12550. Will you tell us what the distinction is?—If you touch the conjunctiva you may get blinking. If you produce the condition of narcosis you get very little, hardly any movement of the eye, on touching the conjunctiva. If you touch the cornea you do get movement.

12551. Strictly speaking, the conjunctiva extends over the cornea, does it not?—Yes, I am speaking of pressing upon the border of the eye lid.

12552. Do I rightly understand that there is a period, in your opinion, in which the corneal and conjunctival reflexes are present, and yet there is insensibility to pain?—The patient, having been in complete anæsthesia, the normal conjunctival reflex may, during the continuance of the operation, be known to pass into a condition where there is slight reaction to touching the conjunctiva, and yet be absolutely free from pain.

12553. Is that condition one of a narrow margin which it is difficult to maintain?—Fairly narrow.

12554. Then in regard to the induction period, as you happily termed it, should I be wrong in thinking that the same period might occur—that is to say, absence of pain with presence of corneal and conjunctival reflexes?—I take it that that just in passing from the second to the third degree, when the conjunctival reflex is very sluggish, when the eyeball is almost fixed, there follows a period of absolute freedom from pain.

12555. Would that be a wider or a narrower margin than the period subsequent to induction?—Narrower.

12556. And more difficult, therefore, to maintain?—Yes.

12557. Have you studied the influence of morphia upon different varieties of the lower animals?—No.

12558. Should I be right in thinking that it differs in its action in the frog from its action in the dog?—No, I do not think so.

12559. Have you studied the physiological influence of curare at all as to whether it be an anæsthetic or not?—Only as a reader of literature. I have never worked with curare.

12560. Do you care to give the Commission your opinion on the subject?—Certainly, if they wish it. I can only go by what I have read. I know there is a case reported of curare poisoning, where the patient expressed himself as not having been conscious of any pain while the surgical operation was being performed. That is the case of Mr. Joseph White, of Nottingham.

12561. Do you conclude from that that curare is an anæsthetic?—That is my impression. I believe the general consensus of opinion is that it is an anæsthetic.

12562. Was that the opinion of Claude Bernard?—No; but a good deal of water has flown under London Bridge since Claude Bernard's day. In fact, we know more about it.

12563. Do you think the restriction in the Act which is at present operative, whereby curare is not held to be an anæsthetic, is erroneous?—No; I think if there is any doubt it is better to have the restriction.

12564. Do you think there is a doubt?—I think there is doubt in the minds of some people.

12565. Have you any doubt in your own mind?—I have an open mind upon the question. I do not know enough about it.

12566. Is the same apparatus used for giving anæsthetics to the lower animals as is employed for man?—What apparatus are you referring to?

12567. You referred to the Wolff's bottle?—We have a very similar apparatus, the Junker apparatus. The principle is very much the same; you pump air through.

12568. (*Sir Mackenzie Chalmers.*) You told Sir William Church just now that you would not recommend morphia as an anæsthetic in the case of human beings. Is that because you doubt its anæsthetic power, or because it has other deleterious effects?—Because it has other deleterious effects.

12569. And in a sufficient dose to produce anæsthesia would it be dangerous to life?—I think so.

12570. When you have been experimenting on animals with anæsthetics, what is the nature of the operations you have had to employ?—Taking blood pressures, examining the action of the heart, and examining the action of respiration.

12571. In all your experiments the animal is killed before it recovers consciousness?—Yes.

12572. Have you seen other people as well as yourself experiment?—Yes.

12573. You said, in reply to Colonel Lockwood, that you had never seen any cruelty. May I put it rather more fully, and ask you: Have you ever seen any carelessness in relation to experiments on animals which has tended to increase suffering?—No, I cannot say that I ever have.

12574. So far as your own personal experience goes, the experiments have always been carefully carried out, and the anæsthesia has been carefully maintained?—Yes.

12575. Do I rightly understand, as regards the administration of general anæsthetics like chloroform, that the sense of pain from the beginning of the administration is gradually dulled, or does it go by stages?—It is gradually dulled. The division into degrees is an artificial one. There is a progressive downward curve of loss of sensation.

12576. So that, with what you would call incomplete anæsthesia, you would have a dull sense of pain, but still some sense of pain?—In some particular animals you might have no sensation; in other more sensitive animals you might have considerable sensation.

12577. Has your attention been called at all to some experiments that were performed by Dr. Crile on surgical shock?—I am aware of Crile's experiments in book form.

12578. May I put this to you? Dr. Crile in his work on surgical shock mentions certain experiments which he performed under what he called incomplete anæsthesia. He was then asked whether those animals suffered any pain or not, and his reply was: "Certainly not; they suffered no pain," although the term that he used was incomplete anæsthesia. What should you say to that?—I should think that probably he used the expression, incomplete anæsthesia, somewhat loosely.

12579. In the sense in which you would use light anæsthesia?—Yes, I should imagine so. Even that would depend very much upon how near complete anæsthesia his incomplete anæsthesia was. He probably meant that he had not got the condition where the animal had completely lost the conjunctival reflex and the eyeball had not become fixed, and so on.

12580. But, nevertheless, it might have reached the stage that you call complete surgical anæsthesia?—Yes, but not if it was incomplete anæsthesia.

12581. He called it incomplete anæsthesia, but said that the animal suffered no pain. Could those statements be reconciled if he was using the term in the same sense that you do?—I do not think he could.

12582. You think he was using the term incomplete anæsthesia (if his statement is correct that the animal suffered no pain) in a different sense from that in which you use it?—Yes.

12583. You told us that you had read the evidence already given before the Commission, I think?—I have read the two Blue Books which have been published.

12584. Are there any comments that you wish to make on any part of that evidence?—I merely came here prepared to answer questions.

12585. Have you seen the evidence of Miss Lind-af-Hageby?—I was reading it while I was waiting to come in here. Yes, I have read some of it.

12586. Where were your experiments performed—at what laboratory?—University College, London.

12587. The same building in which she witnessed certain experiments?—Yes.

12588. Have you read her account in the "Shambles

Mr. D. W. Buxton, M.D., B.S., M.R.C.P.

17 July 1907.

of Science" or in her evidence here of certain movements and cries which she perceived in animals that were being used for demonstration?—I read it in the evidence before this Commission.

12589. Can you form any opinion as to whether they were merely reflex movements, which she misinterpreted, or whether the animals were actually incompletely anæsthetised?—The impression left upon my mind is that she had mistaken reflex movements for movements due to sensation of pain.

12590. In the case of an unskilled person seeing demonstrations of that kind would it be easy to mistake reflex movements for purposive movements, accompanied by pain?—Extremely easy. I have known surgeons to mistake reflex movements for movements of pain.

12591. In ordinary surgical operations, do you mean?—Yes.

12592. You have administered anæsthetics in a great many thousand cases, have you not?—Very many thousands.

12593. In any considerable proportion of cases do you get either movements, or even cries, from a patient that you are satisfied is insensible to pain?—According to the area of the operation you certainly get reflex movements not infrequently. You get cries from patients quite infrequently, but it does occur. One can recognise them by the character of the sound—the absolute difference from articulate speech.

12594. It would only be a skilled person who would recognise the distinction between such cries and a cry of pain?—Yes.

12595. I suppose it is a nervous action?—It is a rush of air through the glottis. I can quite understand a person not familiar with the thing being taken in by it.

12596. Would you get such a cry in the same cases in which you get strong reflex movement, or would they be different cases?—Quite similar cases.

12597. Would it be specially in rectum surgery?—It is very common in rectum surgery. You may get an ascending action of the diaphragm, the air forced out by the diaphragm, when you get what is spoken of as the rectum crowing; the patient makes a curious crowing sound.

12598. Were any of these experiments which Miss Hageby describes such as would be likely to give rise to reflex movements?—I am afraid that I do not remember what the particular experiments were.

12599. (*Dr. Gaskell.*) Have you any definite opinion as to where these different anæsthetics act—on what part of the central nervous system?—I take it that they act upon the whole central nervous system.

12600. Do they act equally, do you think, on the whole central nervous system?—In the case of the general anæsthetics, chloroform, ether, and such like things, I should think their action was one gradually extending from the higher centres downwards if you push it far enough.

12601. That is to say, in your opinion the anæsthetic acts on the higher centres first?—Yes.

12602. Most thoroughly, I mean?—Yes.

12603. The highest centres of all you call the cerebral hemispheres?—Yes.

12604. Would you consider that the anæsthetic action of the drug affected the cells in the cerebral hemispheres distinctly earlier than those in the spinal cord?—I have no doubt of it.

12605. Have you a definite opinion at all where pain is located in the central nervous system?—The perception of pain is in the higher centres.

12606. Do you think that an animal or person deprived of the cerebral hemispheres can feel pain?—No.

12607. You feel sure, for instance, that there would be no pain felt in the spinal cord?—Absolutely none.

12608. When you spoke of reflex action to Lord Selby you mentioned only the spinal cord. I presume that you would allow that reflex actions of the same kind would exist above the spinal cord?—Of course. I only referred to spinal cord reflexes by way of explanation.

12609. So that if the cerebral hemisphere were removed you might still get by reflex action cries?—Yes.

12610. And movements apparently of pain?—Certainly.

12611. Still, in your opinion, there would be no pain?—No.

12612. Do you think that it is very difficult to distinguish between an animal which is making struggles owing to feeling pain, and an animal which is making struggles through these lower centres reflexively. Does it require experience to be able to distinguish that?—Distinctly, I think so.

12613. But, in your own experience of vivisection experiments, you have never felt any difficulty in distinguishing that in an animal?—None of my own knowledge.

12614. For instance, a cry would not be sufficient to enable you to judge whether there was pain?—Certainly not, neither cry nor movement.

12615. Then with respect to such a light anæsthetic or anæsthesia as is given by laughing gas, is it not the experience in giving laughing gas for a dentist that the patient cries often out and struggles?—Very commonly.

12616. And even goes so far as to hit the dentist in the eye?—Yes, I have known it happen.

12617. So have I. Is that a sign of pain?—No.

12618. On seeing that yourself, would you be able to say that the patient was not suffering pain?—Certainly.

12619. And the patient afterwards says he has felt nothing?—Yes.

12620. Have you ever seen any cases of complete consciousness under an anæsthetic, and yet no pain?—I never have; they have been recorded, but I have never seen it.

12621. I once saw Sir George Murray Humphrey give bichloride of methylene to a patient in a hospital, who came round, and I chatted with him during the whole time of the operation. You have never seen a case like that?—No. I have seen cases recorded; I have never seen them myself.

12622. May I take it that in your opinion most definitely a comparatively small, what you would call not a very deep anæsthesia is requisite, and yet you may be sure that the animal does not suffer pain, pain goes first?—Yes.

12623. It goes very early?—Yes, certainly.

12624. You spoke of being able to regulate with certainty the dose of anæsthetics by means of Woulff's bottle, the respiration of it?—Yes.

12625. Could you feel certain that even if that animal had curare by the same method of regulation of the bottle, that animal was all the time completely anæsthetised, using chloroform and ether?—Certainly, with the air passing through, I say so.

12626. You know the case of Bayliss v. Coleridge?—Yes.

12627. In your opinion in that case was there any doubt whatever about the animal being completely anæsthetised?—I have no doubt whatever.

12628. And there is no reason for us to take it, that that is a mode which would give no certainty that the animal was not suffering pain?—Certainly not.

12629. There is only one other question I want to ask you. Have you any experience of urethane?—None.

12630. You cannot give us any advice upon that?—I am sorry I cannot.

12631. (*Sir Mackenzie Chalmers.*) Have you ever experimented yourself with a local anæsthetic on an animal?—Not on a lower animal. I have experimented, that is to say, I have employed it on man.

12632. At present local anæsthetics are not used. They certainly would not be authorised under licences for experiments on the lower animals?—I do not think they are. I have no doubt that local anæsthetics do produce complete loss of pain.

12633. What sort of severe operations have you seen done without pain by means of local anæsthetics?—The removal of breast, tumours of breasts, the radical cure for hernia, removal of testicle, removal of lower parts of the rectum, and amputation of fingers.

12634. Under local anæsthesia?—Yes, you inject it.

12635. By cocaine or eucaine?—Or strovaine.

12636. Is that a new anæsthetic?—Yes.

12637. Have you actually discussed with a patient how far there was no sensation of pain?—Yes.

12638. Or dull sensation?—Yes.

12639. What has been the result?—In most cases they have felt no pain at all. Occasionally they have experienced discomfort.

12640. (*Dr. Gaskell.*) Do you consider that the pulse gives you any indication whatever as to whether the anæsthetic is sufficiently deep to prevent pain?—No.

12641. You could not judge by that at all?—No.

12642. (*Mr. Tomkinson.*) With regard to morphia, morphia, I suppose, was a substance well known, and was discovered long before chloroform?—Yes, opium was known.

12643. It was never used, was it, as an anæsthetic?—Opium was used.

12644. But not to any material extent for deadening pain, was it, in operations?—I believe so. I believe that in the pre-anæsthetic days opium was largely used.

12645. In operations?—In operations, to lessen the sensation of pain.

12646. I thought I had often seen descriptions of the terrors of the operating room?—I daresay. It was not universally used.

12647. I mean, when entirely relieved by any anæsthetic, and consequently the wonderful blessing to mankind of the discovery of chloroform as a real anæsthetic?—I never said it was universally used. I believe it was used in some cases.

12648. Do you hold that persons under the influence of morphia, or insensible, say, from alcohol—that is to say, insensible in the way of taking care of themselves, apparently in a profound sleep—are not subject to pain if they are cut?—I have no doubt of it, that they are not sensible to pain.

12649. You say that the value of anæsthetics has been discovered by experiments on living animals?—The properties of anæsthetics, I said.

12650. How is that specially so, more than experience of the use of it for human beings. You have to rely upon what human beings tell you as to their insensibility to pain afterwards surely, more than anything an animal can tell you?—You can examine the patients' hearts, you see; you cannot open their chests and examine the action of chloroform on the heart, nor can you examine their brain, nor can you examine the spinal cord. With an animal you can discover the action of chloroform or of ether, and you can tell what dose is dangerous, and what dose is not dangerous—whether it affects respiration or whether it affects circulation or other things.

12651. In physiological experiments on dogs, of which you have seen a great many, they are all strapped down first of all, are they not, before the chloroform is administered?—No, certainly not.

12652. Is there not some difficulty in administering it? The dogs struggle against it?—They are in a box; you can put them into a box.

12653. The dog struggles, I presume, to get out of the box?—No, it generally lies down and goes to sleep.

12654. Not at first. In the early stages does it not struggle or bite the box?—As a rule, my experience is that the dog turns round once or twice and goes to sleep.

12655. And then is it strapped down?—Yes, when it is unconscious, and tied on a board.

12656. That, you say, is to prevent reflex action?—No, I did not say anything of the sort.

12657. What is the object?—To keep them in the position required for the operation. In general anæsthesia for man, we strap the man up for operating on his anus. We do not do it to keep him still. We want him in a particular position there, therefore we tie him there, the same as with the dog.

12658. I forget whether you said that you had often seen or administered curare?—I have not.

12659. Do you approve of it?—In what sense do you mean?

12660. Do you think there is danger in it as a paralysing element, and thereby to some extent depriving the animal of the power of showing consciousness in the event of sensibility returning?—I do not think there is any danger, because it is always employed with chloroform or morphia—with some competent anæsthetic. I should not employ it myself alone, because I am not sufficiently satisfied of its action.

Mr. D. W. Buxton, M.D., B.S., M.R.C.P. 17 July 1907.

12661. And in your experience it has not been necessary; you have hardly ever used it?—That is so.

12662. Allusion has been made to Dr. Crile's experiments; you have read of them, I suppose?—Yes, I have.

12663. They were of a tremendous nature, many of them?—Yes.

12664. Do you think there was not danger, in such shocks as that being administered to an animal, of pain being felt, even through the anæsthetic?—None. I think an anæsthetic would be absolutely of no use if you could not safeguard human beings and animals from the possibility of any shock, however severe, making itself felt through the anæsthesia; it would cease to be an anæsthetic. An anæsthetic, to be an anæsthetic, must be capable of preventing pain of any character or kind. By shock, you mean sensation of pain.

12665. In at least one of those operations it was admitted that the dog did show signs of feeling and of pain?—Then it did not have enough anæsthetic.

12666. Exactly; the anæsthesia was imperfect. I think a burner was applied to the dog's nose; it had attempted to struggle as far as possible, and it did show distinct signs of consciousness and pain. You have seen experiments on frogs, have you not?—Many.

12667. Are they anæsthetised?—They are pithed.

12668. Always?—Certainly.

12669. Does that mean the severance of the brain from the body?—Yes, from the cord.

12670. And does it absolutely preclude sensation?—Absolutely.

12671. Is that the case with other cold-blooded animals, too, which are operated upon?—If you destroy the higher brain they no longer can feel pain.

12672. Is pithing resorted to in the case of all cold-blooded animals?—The only cold-blooded animals I have pithed have been frogs.

12673. They are the only cold-blooded animals on which you have seen operations?—I think I may say so.

12674. (*Dr. Wilson.*) But even with pithed frogs it has been contended here that they do exhibit purposive movements. For example, they can reproduce the species—so it has been stated by witnesses. Would that modify your opinion as to whether all possibility of pain is banished by pithing?—Not in the slightest.

12675. Then with regard to these prolonged operations on human beings under chloroform, when slight anæsthesia is maintained towards the close of the operation, have you not to be very careful about varying the dose?—You have always to be careful in giving chloroform to a human being.

12676. You could not keep up a continuous dose as you would through Woulff's bottle?—Certainly you can.

12677. With safety you can do that?—Yes, certainly.

12678. In anæsthetising animals, no matter how severe or prolonged the operation, do you think there is no difficulty at all in maintaining absolute anæsthesia throughout?—I have no doubt of it whatever.

12679. But can there be absolute assurance that there is no pain?—I have no doubt whatever.

12680. In those deaths which sometimes take place during severe operations on the human subject is it not sometimes difficult to tell whether death is due to the anæsthetic or to the shock of the operation while the patient is on the operating table under a severe operation?—You have to decide that upon the merits of each case really. I do not think I can answer generally. I might go so far as to say that I should think you can soon tell. You really have to decide the case upon its own merits.

12681. You believe complete narcosis, of course, is complete anæsthesia, that with narcotics you can induce complete anæsthesia?—Yes, I do.

12682. You have been asked about morphia, and you stated about eucaine, and also urethane; have you any experience with regard to paraldehyde as an anæsthetic?—None.

Mr. D. W. Burton M.D., B.S., M.R.C.P.

17 July 1907.

12683. Do you think it could be used for anæsthetising animals?—I have no idea. I have no knowledge of it.

12684. Have you ever anæsthetised animals for operations on account of disease or accident?—Yes, I have.

12685. And do you observe the same rules then as are applicable to human beings?—Yes, quite.

12686. But not exactly the same rules as are followed in a physiological laboratory?—Probably it is done in a more formal manner. I spoke about a dog being put into a box. On occasions when I have had to chloroform a valuable dog, or the dog of a friend, I have not put it into a box; I have put it on a table, patted it, and given it chloroform, which it has inhaled, and gone off without any sign of discomfort or fear.

12687. You would not think it necessary to use Woullf's bottle?—I should think it was very convenient to use a Woullf's bottle, but not necessary.

12688. (*Sir William Church.*) I should like to ask you one question, because I think, perhaps, some of the public and some of the Commission may not put a right interpretation upon the illustrations, which show the boards that animals are strapped upon for some of these operations. That is to keep them not quiet, but to keep them in a special position in order that the necessary operation can be performed, is it not?—Quite.

12689. It is equivalent to the fact that even still, for a large number of operations for men, it is found that it is advisable to strap the patient into a certain position before the operation begins?—That is so.

12690. Then from your experience you tell us that that is a necessity which very frequently arises in the practice of human surgery?—Certainly.

TWENTY-EIGHTH DAY.

Wednesday, 24th July 1907.

PRESENT:

The Right Hon. The Viscount SELBY (*Chairman*).

Colonel the Right Hon. A. M. LOCKWOOD, C.V.O., M.P.
Sir W. S. CHURCH, Bart., K.C.B., M.D.
Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. A. J. RAM, K.C.
Mr. W. H. GASKELL, M.D., F.R.S.
Mr. J. TOMKINSON, M.P.,
Mr. G. WILSON, LL.D., M.D.
Captain C. BIGHAM, C.M.G. (*Secretary*).

The Right Hon. Sir JOHN FLETCHER MOULTON, called in; and Examined.

12691. (*Chairman.*) You are a Member of the Privy Council, a Fellow of the Royal Society, and a Lord Justice of Appeal?—I am.

12692. For many years you have taken an interest in the progress of curative science?—Yes, I have taken a very keen interest in it both from the scientific side and also from what is called the ethical side. Having been a politician, and realising that the public take to themselves the right and the duty of controlling everything that goes on in the kingdom, I have realised for many years that the question which this Commission is directed to consider would come on in some form or other in the way of an inquiry; that, in other words, the justification for scientific research in connection with curative science would be examined. As I have in many other things observed, the advance of science takes the workers in science more and more beyond the ken of the ordinary public, and their work grows to be little understood and much misunderstood; and I have felt that, as in many other cases, the need would come for interpreters between those who are carrying on scientific research and the public, in order to explain and justify their work. The consequence is that I have considered the subject very much from the very point of view from which this Commission has to consider it. I have come, many years ago, to a very deep conviction upon it, and therefore I am glad to have the opportunity of putting before this Commission the reason for the faith that is in me.

12693. You say that you have taken great interest in the subject for a long time, and I believe you have very closely watched what has been going on with reference to it on both sides?—Yes, I have watched it very closely on both sides. Of course, you quite understand that so far as the scientific side is concerned, though I am qualified to judge of the scientific results and of the evidence for them, I am as an outsider immeasurably less qualified to speak with authority on the scientific points themselves than are some of those whom you have had before you; but, on the other hand, I think that with regard to the scientific methods and with regard to the bearing and meaning of the results upon the subject of this Commission, I am, as a close observer from outside——

12694. A highly qualified observer, I may say for you?—I am qualified to give some assistance to the Commission.

12695. In your long experience at the Bar, before you went on to the Bench, you were specially interested and employed in matters that dealt with questions of scientific investigation of all kinds?—Yes; I have had, I think, unrivalled experience in being what I have described as an interpreter between those who are doing the pioneer work in science and the people who have to judge of the results of their work; and it is, perhaps, more from that standpoint than from any other that I desired to put my views before the Commission with regard to this question.

Sir J. F. Moulton.
24 July 1907.

12696. In your view, I understand, the real issue raised by the agitation against experiments on animals is, whether or not curative science shall be studied experimentally or whether it shall become a purely observational science?—Yes. I think that in the controversy a great deal has been lost by looking at it in too narrow a light. It is not a question of vivisection—that is to say, the performing of cutting experiments on living animals; that is a mere nickname, a mere catch phrase which was originally invented, I have not the slightest doubt, for purposes of prejudice. I am not saying that with any desire to find fault. One always likes to get a name which expresses one's own point of view without further explanation; but it is a most imperfect representative of the real issue. The real issue is whether curative science is to be an observational science or whether it is to be an experimental science, and, as I shall hope to show this Commission, the importance of the decision of that issue is impossible to be exaggerated. But I shall deal with that a little later on, after I have dealt shortly with the grounds of the opposition to its being an experimental science.

12697. You have something to say, I think, on how far the opposition is based on humanitarian grounds?—Yes, the opposition purports to be based on the principle that we are bound to regard the sufferings of animals, and that the avoidance of the suffering of animals is a motive which ought to influence every man with a conscience. It is a consequence, no doubt, of a change which has come over the views of mankind decidedly in the right direction. Of old, cruelty was thought nothing of, whether it was to men or animals. You cannot read the history of the world down to, say, the seventeenth century, without feeling that there was an extraordinary callousness to suffering of every kind. A great change from that time has been passing over the world. First, there came the regard for the sufferings of men, and cruelty towards men gradually passed out of favour; and now the thought of human suffering and the desire to avoid it is one of the most unquestioned and influential motives that guide the action of mankind. Presently there followed on that the extension of the feeling to the sufferings of animals, and there is no doubt that now, with the best part of

Sir J. F. Moulton.

24 July 1907.

humanity, sympathy for the sufferings of animals and the desire to lessen those sufferings are most influential motives of action. Now that appears to me all in the right direction, and so far as my opinion goes it is not only not contested by either party to this controversy, but both of them would in words accept it as a duty to lessen so far as possible the sufferings of animals as well as of men. I do not wish to be misunderstood when I talk about the sufferings of animals in the same breath, as it were, with the sufferings of men. I must therefore point out a very broad distinction between the two, which must be borne in mind if we are to come to right conclusions in this matter. The sufferings of animals are substantially physical only. The sufferings of men are not solely physical. Almost as important a factor in that suffering is mental suffering, arising partly from a man's relations to society—that is to say, that death or sickness will cause pain and suffering and trouble and misery to those who are intimately connected with the man, and partly in the individual himself. He is capable of feeling anxiety, regret, dread, and many other things which are of the most serious importance in measuring human suffering, but which are practically absent from animal suffering. I do not say this in any way to detract what I have said about the importance of avoiding and preventing, so far as we can, animal suffering; it is only that we may keep true our ideas of what suffering is, and to do that, one must bear in mind the broad distinction I have just mentioned.

12698. You mean that if a man and an animal have each to be subjected to a serious operation under anæsthetics, the whole of the pain and suffering that the animal experiences after it is properly anæsthetised and dies under the anæsthetic, is covered by the anæsthetic?—Yes.

12699. And it has not suffering before or after?—No.

12700. But in the case of a man, he has the suffering of anticipation, thinking of the future, of those who belong to him, and if he dies he has the suffering of his family. If he survives, he has suffering from that again, which may amount also to disablement and loss of some of his functions?—Yes, that is a very striking example of the difference, and it brings out one other point which you must also bear in mind, and that is, our responsibility with regard to mankind as compared with our responsibility to animals. In the case of an animal, if the future is to be a future of pain we unhesitatingly kill it. No matter how certainly the future must be a future of pain in a man, we must by universal acceptance keep him alive. Therefore in deciding on our duty to men and animals we have to realise that no matter what be the consequences we have no right to decide with regard to man as to whether it is better to terminate his sufferings or not. If you take the case of a man with some terrible disease over him which may perhaps be cured by an operation, he has the terror of the uncertainty of the cure. The operation is fortunately under anæsthetics, and he does not feel it, but afterwards there may come an only partial cure, and a painful life ahead of it. Not one of those elements exists in the case of the animal. The animal, if the pain is going to be greater than the value of life, is put out of the way painlessly. So that we must remember that distinction, because it is not permissible in a serious inquiry like this to shut our eyes to any truth. There is no safe side on which one may lean in the way of exaggeration in the examination of a question like this, and although you are going to be loyal to the duty of lessening the pain of animals, you must not mistake the relative position of pain with them and pain with us.

12701. You admit that there is a responsibility on everyone who operates on animals to avoid unnecessary pain?—Oh, yes. In fact, I go further, and I think that one ought to admit as a fundamental principle that it is the duty of all men to work for diminishing pain. The diminution of the totality of pain in animals and in men ought, I think, to be a guiding motive and a prominent motive in the case of people in the position of those who are working in curative science, and also in the position of people in ordinary life; and in my opinion it is just as operative, and, if I might give my private opinion, it is far more operative in those who are connected with the curative sciences than in the people who attack them so bitterly. And it is for this reason: Because those who are dealing with the curative sciences are perpetually brought in face of pain, and it is a point of honour with them to conquer that pain and relieve it, till that aim becomes to them a kind of second nature—a kind of all-pervading motive.

12702. You are speaking rather, are you not, of the practising physician or surgeon than of one who devotes himself entirely to research?—I am; but the reason why I cite that is this, that there is an almost unanimous opinion among those who are engaged in the practical work of the curative sciences in favour of experimental research in connection with them. That support has been discounted by people saying: "Oh, those who are engaged in curative science get callous to pain." Now, in my opinion, they are more sensitive to pain, because it is perpetually appealing to them, and, if I might say so, it is the life-long foe which they are engaged in fighting. I mentioned therefore the extent to which the desire to diminish pain was present to those who are engaged in it, not so much as dealing, as you say, with those who are engaged in research, as with those who, with a full knowledge of the matter, give them their support in order to point out that that support has the very high sanction of coming from people who all their lives are fighting pain, and fighting it often at very great personal discomfort and self-sacrifice, till it has become to them, as I say, an almost all-dominant motive. The difference between the two schools is this: Those with whom I range myself, who are desirous of extending and supporting experimental research in the curative sciences, consider not only the pain that is inflicted, but they consider the pain that might be prevented, and they hold themselves responsible for permitting pain which they could stop, just as much as for inflicting pain deliberately—they look at the two together. The other school consider only inflicted pain. They think it their duty to prevent pain being inflicted, even though the infliction of pain may lead to the prevention of many times that much pain in the future.

12703. Of course, your argument, if carried out—I am not disputing it, or offering any opinion about it—would lead to this, that if anæsthetics had never been invented, you would still be justified in carrying out experiments on living animals, and inflicting the necessary pain upon them for the sake of the knowledge that would be acquired in the saving of pain in the future?—It would; but if you will allow me I will put my practical conclusions latest. I want first of all to lay down the foundation of the decision. I want to get before the Commission the fundamental principles as I view them, and to establish them, and then I propose to take the practical conclusions, when I will deal with such a matter as you have referred to.

12704. But, of course, the actual fact that anæsthetics and their use have been discovered now does not render the argument I was putting a very practical one. It is rather a logical consequence than a practical one?—Certainly; I quite understand that. Now I want the Commission to allow me to take what I may call a simile or an illustration. I am going to take a case which in my opinion exactly represents the attitude of the two rival schools; it is not connected with experiments on animals at all, and that is one of the reasons why I have chosen it. I want the Commission to understand it that I take as explaining my views, and I shall trust to bring the question which is before this Commission up to the level of this illustration. I will suppose that a ship which is plague-stricken, and has got rats on board, arrives at a port. A man with a sense of his responsibility, knowing that there is high probability that rats convey the plague, would unhesitatingly extirpate those rats, even though his only method of doing so was by putting them to a painful death, whether it was by poisoning them with phosphorus or by stifling them, or by even more painful methods. He would not hesitate; he would feel it his duty to extirpate them. Now, supposing that a person were to come and say, "I could not bear to see those poor creatures running for their lives and in danger, trying to save themselves from their relentless pursuers, and so I let as many as I could escape," I have no doubt that the person who did that would think that he acted from humane motives. But what would be the consequence? It might communicate plague not only to a town, but to a whole nation. It might bring positively measureless misery. The first man would be right, because he would look at the inflicted pain which would be to the bad side of the ledger. No one would have a right to inflict that suffering merely capriciously. But he would see beyond that pain he was inflicting—that in acting thus he was preventing an amount of pain which was beyond all measure greater than that which he was inflicting; and if he was a man to whom pain appealed, who had a heart which felt keenly suffering whether in men or animals, he would do it all the more unhesitatingly. The other man would

think only of the inflicted pain, and say, "I am too tender-hearted to inflict it." He would not consider that by not doing it he was causing preventible pain on such an enormous scale. That is typical of the struggle between the two parties. I have chosen that example, not because it is an exaggerated one, or because it is an unfair one. I have chosen it because in that case there is no veil between the act and its consequences. One can see plainly that the letting free of those infected rats might produce those consequences. But now just let me take a hypothesis. I will suppose that, instead of its bringing a plague, the killing of those rats would lead to the discovery of the antiseptic treatment. That antiseptic treatment put an end—substantially, of course, I mean—to an amount of human misery that we can scarcely realise. The suppuration of wounds, accidents leading to months of painful sickness and a recovery which was only partial, and left the people maimed, the horrors of war doubled, the deaths in war enormously increased were all consequences of sepsis — it was just as bad as a plague. Now, instead of its being a question of "either you extirpate the rats or you have the plague," it had been "either you extirpate the rats or the antiseptic method will not be discovered, and the suppuration of wounds and all the horrors which follow from that must remain in the world," you see at once that to the thoughtful man the argument in the two cases is precisely the same—"If I do not inflict this pain I permit an unmeasured amount of pain which I could prevent." In my opinion, when you once see clearly the causal connection between the pain you inflict and the diminution of pain which follows from it, it makes no difference in what way it follows. Your duty is to take that line which produces the minimum total pain, and whether the pain is inflicted pain or whether it is preventible pain which is not prevented is in my opinion one and the same thing.

12705. Supposing that you have not got an immediate prospect of preventing pain or of preventing septic conditions, but are pursuing these experiments for the purpose of acquiring knowledge that you do not possess, with the hope and belief that it will lead to some good, how do you deal with that?—You have anticipated the very next step which, in my opinion, we have to take in the examination of the subject. The reason why I gave this illustration was that I wanted to put before you by an example the criterion which I say every humane man ought to follow. It is that he ought to take that line which before his conscience he thinks will lead to the diminution of total pain, and if he is satisfied that the infliction of a certain amount of pain is the right way to diminish the total pain he is bound, from his very feelings of humanity, to take it. And now you say—and, if I might respectfully say so, quite rightly—if that is going to guide you in a matter of this kind, you must be satisfied that a man ought to realise that the practise of the experimental method is the wisest way to work for the diminution of the totality of pain. If I have brought the question to this point it is all I want to bring out of the example which I have taken. I admit that those who claim that they should inflict pain are bound to show that it is the wisest thing to do with the view to reduce the totality of pain. But I want to point out one other thing, and that is this—that a man would be bound to take the same course with regard to the rats if there was not a certainty, but a reasonable ground for thinking, that plague would follow. He would have no right to say, "It is not demonstrated; I will risk it."

12706. There is a case, of course, beyond that, where a man is making experiments upon a living animal with a view to ascertain precisely what the action of certain parts of the body is—what their functions are?—Yes.

12707. Not that he can point to any particular saving of pain or good that can be done by it, but he is doing it to acquire knowledge which he does not possess, with a philosophic belief that it will lead to the good of reducing pain?—It is a real pleasure to me to have such points put to me, for this reason—it convinces me, as indeed I knew before, that I have the honour of speaking before those who have thought very seriously over this matter, and realise the various points which arise. You will find that I shall take that point up in its proper place; because, in my opinion, it is of the greatest importance that we should face specific questions of that kind. You cannot, in this matter, come to a wise conclusion by simply dealing with vague generalities. But if you will allow me, I will take it up later, and you will find, I think, that I have put it in its logical position. Now, I said that I took that example of the plague-stricken ship, not because it was exaggerated, but because there was an obvious connection between the act and its consequences, and then I pointed out that if you could get an equally obvious connection between pain inflicted and a great discovery it would be the same thing. I said that the parallel I have taken was not unfair to either of the two parties, and I want to digress for a moment to show that I am justified in saying so. I think if you were to ask a man who had given thought to the matter, who, of all living men, had been privileged to do most to reduce pain, the answer would almost, without exception, be "Lord Lister," who introduced the antiseptic method, which has been followed now by the various aseptic and antiseptic methods which obtain all over the world. Yet I saw the other day in a paper that at an anti-vivisection meeting Lord Lister's name was mentioned, and it was greeted with shouts of "Brute." They called a "brute" the man who had done most of all living men to lessen pain. And that was, if I might say so, perfectly consistent. They knew that he had voluntarily inflicted pain in his experiments, and that was all that they looked to; and they did not realise that if their real motive, the thing which was the real spring of their action, was the desire to lessen pain, Lord Lister's name should have been the most highly honoured of all. Now, I am not speaking bitterly at all of these people, though I oppose their action so much; I only want to point out that they are acting according to the effect on their emotions of the contemplation of pain; not according to the pain itself. The prevented pain, which has made Lord Lister's name so esteemed, is not present to their minds. The inflicted pain strikes their imagination, and the consequence is that they, with the best of motives, denounce him because he is willing to inflict pain, without realising that he, who is the most capable, at any rate one of the most capable, of all men to know the ultimate result of his actions, has been doing it for the purposes of reducing suffering, and has succeeded beyond all hope. So that I am not treating those who oppose me unfairly in pointing out that they do not regard the more distant consequences of their action—they only regard the question of the immediately inflicted pain.

Now, I want to go on to what the Chairman has put to me, viz., that I must establish that experimental research is the wise mode of action if we wish to diminish pain. I start from the following fundamental facts. I say that if you look round the world, the only way in which we can diminish pain is by human action. Animals go on regardless of the pain they cause to one another. In fact, the universe is built on pain. Whole races of animals live simply by killing other races and killing them without the slightest regard to suffering. So that we must look to human action alone to diminish pain. Now, what is it that prevents our diminishing pain in the world? One feels at once that it is not the absence of desire to do it. I believe that desire is very prominently present. It is because we do not know how to do it; it is our ignorance. Take the case of doctors. Doctors are as desirous as they can possibly be of lessening suffering in the world, and yet how often they stand by the bedside and the patient goes on suffering and they can do nothing. Now, the absence of our power of diminishing pain is due to ignorance, to our not understanding two things. First, not understanding the causes which excite pain; and, secondly, not understanding the action of those causes on the organism—that is to say, how it is that those morbid causes, if I might use the phrase, produce pain? I call the first one (simply to distinguish it) the pathological factor—that is to say, what are the springs of disease; and the other is the physiological factor—that is to say, how those springs of disease cause pain in the organism; that is just a division for convenience of the knowledge which we must possess in order to be able to lessen and control pain. Let me give an example of the way in which lack of knowledge increases suffering. The discovery that the organism could, by means of anæsthetics, pass into unconsciousness without passing into death, and that all the living operations could go on equally vigorously while consciousness—that is to say, the possibility of pain—was entirely suppressed, led to the use of anæsthetics, and, as a consequence, to the diminution of suffering, both directly during operations, and indirectly in increasing the possibilities of surgery. Without the knowledge obtained from that discovery men were obliged to perform operations in the brutal method of the old surgeons, because there was no other alternative. This is only an example of the way in

Sir J. F. Moulton.

24 July 1907.

which our power is limited by our knowledge. And I wish to point out with regard to this point, that here again we have no difference of opinion. Not only the whole medical profession, but the whole public agree that doctors ought to be armed with all the knowledge of the time. There is no difference of view as to this. Every attempt is made to increase the efficiency of the education of the doctor; because we feel that by arming the doctor with the knowledge of the time we arm him as best we can with the means of diminishing pain. That, of course, is true with regard to the knowledge that has been attained during the last, let me take it, 40 years—the only years as to which I can speak; and that knowledge has been mainly due to experimental research. Therefore all must feel that this knowledge which has been obtained by experimental research is useful for the purpose of lessening pain, because we try our very best to make all those who are engaged in practical curative work masters of it. I do not think I need point out to this Commission further how all-important knowledge is where you are dealing with organisms, and you want to stop suffering.

There is one other thing I want to say, and that is this. That our inability to stop suffering, owing to absence of knowledge, is not only to be found in the case of obscure diseases. They afford striking instances of it, no doubt, and are by no means rare. I should think there are very few of us who have not seen those near to them suffer from diseases which have baffled the doctors, and whether or not they could be eased or saved was decided by whether or not the doctors could read what was the cause of the trouble. A friend of mine has just died, apparently of a painful disease, which the doctors could not touch. A *post-mortem* showed that it was only because they did not realise what the true cause of the disease was; it was one which might almost with certainty have been relieved. Such diseases may have marked symptoms, but the doctors are unable to read from those symptoms what is the cause, and therefore they cannot fight the cause. But, although these cases are striking instances of the principle, they are nothing like the most important; the most important are diseases which are quite common, of which we cannot yet find the cause, and not finding the cause all we can do is to deal with the symptoms.

12708. I think we all agree that there is a very vast field of medical knowledge yet; I think every medical man would agree to that, as well as ourselves. But really, the question is how far that knowledge can only be found in experiments upon animals?—Precisely. That, I think you will find from the *précis*, is the next point I want to mention. But I wished to put in the forefront that it is want of knowledge which prevents our diminishing suffering, because I shall trust to show to this Commission that the pole star by which we steer is knowledge. It is ignorance that hampers us. I am using the term ignorance in a sense that will not, I trust, be misunderstood. I am aware of the gigantic amount of knowledge that the present and past members of the medical profession, and those who have been engaged in research, have already accumulated, but what I mean by ignorance is the vast field of what yet may be known, but is not at present known. I desire to impress upon the Commission that that is the real cause of our impotence. Now, let me take the question of how we are to get rid of this ignorance—and here we are on firm ground. No man who knows anything of science has any doubt whatever that the right way to advance knowledge is by experiment. You can take the whole range of the sciences, and I would challenge an opponent to name one in which advance, if it has been rapid and striking, has not been through experiment. Where we are reduced to observation a science crawls. Where and in proportion as you can use experiment, the science advances rapidly. I could take any science to show that; it is much easier to show that experiment has led to advance than to find a case in which advance has been made purely by observation; because a scientific man rushes at once to experiment if he can do so. He adds, of course, the testimony of observation—that is extremely valuable for the purpose of guiding and starting his experiment; but everybody knows that each observation becomes only the nucleus, or, rather, the basis, from which you start your experiment. I was puzzling to think of some branch of science where there was only observation, and the only thing I could think of was the case of volcanoes. Now, there is not anything that has attracted human attention more, or fascinated it more, or has been on a bigger scale or more open to observation, than volcanoes; and yet we are almost in the same state of ignorance of the origin and the *modus operandi* of volcanoes as Pliny was.

12709. The difficulty is just as great now as then for anybody to go down a volcano when it is in eruption?—Precisely. In no way can you bring experiment to bear upon it. As soon as you can bring experiment to bear upon a subject you are free; but as long as you can merely observe, your progress is very slow. The reason is that experiment is like cross-examination. You can put the question you want, and Nature always answers it. She does not answer the question you meant to put; she answers the question you actually did put. She swears by the card in the most shocking manner. She does not care in the least what you meant to ask, but she does care what you asked, and she answers it with perfect truthfulness. And the consequence is, that when you adopt experiment, the great experimenter can put a question, the answer to which lets the whole secret out. I am going to give an example that I remember impressed me very deeply. I cannot tell how many years ago, but it was just about the time when it was first discovered that guinea-pigs were susceptible to tuberculosis. I heard from a friend that a doctor of his acquaintance, a practising physician, I suppose, had been troubled as to whether consumption was a communicable disease or not: I should say that the vast preponderance of opinion at that date was that it was hereditary. I remember, as all of us remember when we were young, the way in which consumption would, as it was called, go through a family, and it was thought that this was because it was in the strain. Then some bold people suggested that it was possible that it might be due to its being communicable, although probably to the ideas of that time it looked about as likely to be communicable as a spinal disease. What that doctor did was this: He took a dozen guinea-pigs, divided them into two sixes, and he let one six have the run of the wards of a consumption hospital, and the other six have the run of the wards of another hospital, just about in the same conditions of temperature; he left them there for the requisite number of weeks, whatever it was, and then he killed the whole dozen, and he found that the six which had been running in the consumption hospital had tuberculosis, and that the six that had been running in the other hospital had no trace of it.

12710. (*Chairman.*) The other was not a consumption hospital?—No, it was not.

12711. (*Sir William Collins.*) Whose experiments were those?—I cannot tell you the name of the doctor, because it was not given me, but I heard it long ago, in the early days of research upon tuberculosis, and I believe it to be true. But if it was not actually performed, it would still serve as a typical example of experiment. I have no reason to doubt that this experiment was actually performed, because the man who told me was a most intelligent man, and he told it to me at the time as having been done quite privately, by a doctor whom he knew, in order that the doctor might settle the doubt in his own mind.

12712. (*Chairman.*) You would say that it is rather an illustration than a typical example if it is not given us at first hand in some way?—You may take it simply as an illustration, although the very thing has been done, I know, by other people. Klein did it. If you remember, Klein put guinea-pigs into an air shaft which led from the wards of a consumption hospital, and found that they developed tuberculosis. But we will take it merely as an illustration. I am not basing anything on the fact. What I want to point out is this, that such an experiment would settle the question more than would twenty years of observation—I might say a century of observation—for this reason, that you had placed these similar animals under entirely similar circumstances, with the exception that in the one case, but not in the other, there were present in the immediate neighbourhood persons who were sick of the disease, and you will find as a result that in the one case they become sick, and in the other they do not. There is no question of heredity, and there is no question of the acquired disease being the consequence of different circumstances of living, of different circumstances of nutrition, or anything of that kind. The only thing that is present as a cause is the neighbourhood of the sick people in one case and not in the other. In the result the difference is disease in the one and not in the other.

12713. What was the fact that it was wanted to

discover there—whether guinea-pigs could take the complaint?—No, whether the disease was communicable from one person to another.

12714. But there are plenty of examples of people who have not tuberculosis daily frequenting hospitals and not acquiring it, are there not?—Oh, yes; but the point of the experiment was not under what circumstances was the disease communicable, but whether it was communicable at all. Just take the case of persons who are ill of spinal disease.

12715. I follow you?—Their relatives go freely among them, attend to them, and try to make their sickness as easily borne as possible. And so it undoubtedly used to be when members of a family were sick of tuberculosis. Everybody thought it was only kindness that the brothers and sisters should attend to their sick sister, and nobody thought that there was danger. But when you had found that this was a communicable disease, your duty with regard to children and other people in the presence of the disease became very different, and it was only to find out this that the experiment was tried. The experiment showed affirmatively it was communicable. That was only, of course, the first of a necessary series of experiments to show how it was communicable; but from that moment that doctor knew how great was the responsibility of allowing people to attend or be in intimate contact with one who was affected by consumption. Just try and see how you could get an equal degree of certainty from observation. You take a case where it has run through a family. Yes; but it might be that it was hereditary in the family. Then you find that in a particular place it is very largely prevalent. Yes; but that may be because, as compared with other places, the climate or soil of that place produces a predisposition to it. Neither group of cases points necessarily to communicability. Some people will be struck in one way with a series of these cases, others will be struck in another way, and there will be a perpetual conflict as to which is the true explanation. But when you take such an experiment, there is not a doubt; you cannot explain it, except that the disease is communicable. And the consequence is that you commence your further examination with the consciousness that it has been demonstrated that it can pass from the sick to the well. Now, I was very much struck—as illustrating the impossibility of arriving at these things by observation—by a piece of cross-examination by Sir Willian Collins of one of the witnesses before the Commission; it illustrated it in the most striking way. He was dealing with the result of the serum treatment of diphtheria. An appeal was made to the statistics of diphtheria hospitals in London, and the witness said: "Oh, the serum treatment is demonstrated as being a great success, because you have here the same hospital in the same place dealing for a consecutive number of years with the same population, and the statistics show a great diminution of the percentage of deaths after the introduction of the serum treatment." Sir William Collins, if I might say so, quite justifiably cross-examined on that. He will know whether I am fairly representing him, but, as I remember it, he asked are we now getting the cases earlier; is it not true that we have made such advances in the diagnosis that we know better what is diphtheria and what is not? And he went on pointing to differences in the circumstances of the earlier years and the later years as taking away from the conclusiveness of the statistics.

12716. (*Sir William Collins.*) As an element that required consideration?—Exactly, as an element that required consideration. That is perfectly fair. Statistics that are got in that way must be rightly open to that criticism. And this is the reason: You dare not let the children wait in the later years so as to make the time at which they are taken up for the purpose of treatment comparable with what it was in the earlier years, because you are bound to do for every child the best thing that you can, and the consequence is that you dare not make your experiment scientifically more perfect, because there is the paramount duty towards human life. Now, you could not have had a stronger case, *i.e.*, one in which the observational method was working under greater advantages. You had hospitals devoted to this disease alone, dealing, as I have said, with the same population, in the same place, under, as far as possible, the same circumstances; but you could not, and you dare not, and you ought not to, make the circumstances identical because of your duty to the individual. Compare that with the case I was putting forward of the guinea-pigs; I could give another and more striking example, which is the classical experiment in connection with anthrax, in which, after Pasteur had worked out the treatment by inoculation against anthrax, he took 50 sheep for his experiment; 25 of them were inoculated and 25 were left uninoculated. Then the whole of the 50 were inoculated with virulent anthrax, and within four or five days every one of the 25 that had not been inoculated died, while of the others 24 were alive, and one was shown to have died from things unconnected with anthrax. You see by these examples how in experimental research you can make the circumstances identical, and one experiment of that kind (properly repeated, so as to eliminate error) gives you a certainty that years of observation could not give. And all those years of observation have paid their toll in suffering. It is no use saying, Well, we shall learn in a few years hence, instead of learning it now. All that time there has been preventible pain, which has not been prevented because you have not known how.

Sir J. F. Moulton.
24 July 1907.

What, therefore, I want to point out is that we know that the way to acquire knowledge with certainty is by experiment; it follows from its very nature, and from our universal experience in all sciences, that this is the way in which you best acquire knowledge, because you can make each experiment answer some critical question. You can arrange matters so that you have two cases precisely similar in all respects, save that the one is without that cause present and the other is with that cause present, and the contrast gives you a light which you could not get from observing instances where you cannot eliminate other causes. The more complex the subject is, the more factors there are at work, the more essential the experimental method is; and the most complex of all phenomena are those that relate to living beings. I am sure there are those here who have made experiments in connection with life, and know from experience the truth of what I say. The number of factors at work is so large, the difficulty of isolating them is so great, that it often takes very much longer to realise how you can put the question to Nature than it does to put it, and to draw your conclusions from it when you get the answer. But the more complex the subject is, I say the more are your driven away from observation, which only gives you the total result of many causes which are varyingly present in all cases, to something which will enable you to isolate several of the causes and determine separately their effects.

12717. (*Chairman.*) That brings you, I think, to the question which I was putting to you about pure experimentation, and the justification of experiments on animals where you have no specific disease in view?—Yes. Many will think me a heretic on this point, but I have a strong view that, when you have once realised that experiment is the right way to acquire the necessary knowledge, it is a bad thing to work too directly and too consciously for practical results.

12718. When you call that a heresy, of whom are you speaking as the orthodox?—Most people say that you should only make such experiments with the direct view of some practical application for the benefit of mankind.

12719. We have had a good many witnesses before us who take what you call the heretical view?—I am delighted to find that I am not alone.

12720. As well as those who take the other view; and others who would say that you do not go far enough?—I am glad to find that I have got my comrades. You must not misunderstand me. I think that the object and the reward and the ultimate justification of research is the benefit it confers. But what I wish to urge is that it is unwholesome to keep that before your mind when you are working, at all events, in the earlier stages. May I give a parallel which I think explains and justifies this view? I take the history of alchemy. For centuries men of the highest intellectual attainments—for there can be no doubt of the ability of the men who worked at these subjects—worked hard at the transmutation of metals, and the result of those centuries has only been snippets of knowledge, if I might use such a phrase. I do not undervalue them; they gave us, I believe, some very valuable reagents, but that is practically all. And the reason was that they did not commence by working so as to get to know the nature and properties of the things on which they were working; they worked straight for a result.

Sir J. F. Moulton.

24 July 1907.

12721. For an impossible result, was it not?—It may have been an impossible result. But whether it was impossible or possible would have made very little difference if they had commenced by laying the foundation in knowledge, because, although we should not have obtained the transmutation of metals, we should have had modern chemistry some three centuries earlier than we did. But they only worked for a result.

12722. They did not care about chemistry. Their researches were not chemical researches?—Well, transmutation of metals was intended to be a chemical triumph. If I might take a parallel in curative science; this work was like the shots at specific cures for cancer—violet leaves and all that sort of thing—made by people working straight for a nostrum that will cure a disease like that, the nature of which is shrouded in such mystery.

12723. I only meant those people were fighting a particular disease which they had before them, and which was evident under their eyes, and they were seeking remedies blindly?—Yes.

12724. The other people were seeking something in the clouds altogether; they were not pursuing what you would call chemical research, although they used certain chemical experiments?—But if they had only laid a basis; if they had only worked at it as you try to reduce a fortress, by parallels, where each parallel brings you nearer to the fortress. If you attempt to take it by a rush and fail, you are no further than you were before; but if you make your parallels you are so much nearer, and that is a permanent advance. Just in the same way I think that if I were to ask any scientific man of position in the medical profession, "Where do you look for the solution of the great problem of cancer?" he would say, "I look to a gradual acquisition of knowledge about it, and the breaking up of the obstinate silence of the disease which will tell us nothing, neither its preferences nor the things it dislikes, nor its origin, nor anything." Such men do not give much heed to the investigations aimed directly at its cure, because they do not believe they will succeed. They believe that we shall have to know a great deal more about the disease itself before we know in what direction success can come. But what they do think is this, that by gradually acquiring knowledge of it, knowledge acquired quite independently of whether it is a thing we could use or not, the disease will gradually cease to be a mystery, and when it has ceased to be a mystery we shall find some weak point in its armour. Therefore I am satisfied that the wisest thing to do is to realise broadly that our ignorance of the springs of disease and the nature of the organism that suffers, are the cause of our powerlessness, and that all research which is intended to lessen our ignorance is in the right direction, and that it is in vain for us beforehand to say which will soonest lead to a beneficial result. I feel, therefore, strongly that this is the principle which, with proper regulations and restrictions, we ought to accept; and that we ought to fix our eyes on knowledge and not on immediate promise—immediate promise is likely to be delusive—and when I come to the instances by which I trust to justify the serviceability of experimental research, I think I shall be able to show that those things have sometimes reaped the richest harvest in which the promise came quite late.

12725. You think, to sum up that part of your evidence, that the experimental method is justifiable even though you have no immediate practical object in view beyond the acquiring of knowledge and the hope and belief that it will lead to some ultimate useful purpose?—Yes, you have the hope and belief that it will, and you have the certainty that it is the right way to work for it. Where you are ignorant of the evil and ignorant of how it operates, you are like a hunter who is not yet on the trail of the fox. He has to cast about in order to come upon it. Similarly, it takes a very great deal of experiment to know in which direction practical success may be looked for.

I want to say one more thing before I go to the examination of whether, as a matter of fact, the experimental method has shown itself to be of this great practical value, has thus justified its use. So strongly do I hold that what we ought to fix our eyes upon is the acquisition of knowledge and the removal of ignorance, that if I was here without being able to show a single practical result of experimental research in curative science I should give evidence in the same direction, and so far as I personally am concerned with the same confidence, for this reason: Supposing I was to go back, say, 40 years (I am not suggesting for a moment that prior to 40 years ago there was not a great deal done in research, but I take that period as including the great outburst of experimental research, beginning with the early sixties and since then) I should have all my data. I should have the fact that ignorance was vast, vaster even than now, that ignorance paralysed our power of preventing suffering, and that the right way to get rid of that ignorance was by the experimental method; and therefore, even though I could not show that we had obtained any practical results, I should say to this Commission, if it were sitting in the early sixties, that it was their duty to take care that experimental research was not hindered. The idea that you do not justify experimental research unless you can show that it has already produced practical results would make it never justifiable to commence it, and, in my eyes, it would be just about as ridiculous as to revile winter sowing because in April there were no crops. The moment when the practical results come depends upon the nature of the subject. You cannot foresee it; they may come at a burst. After long investigation which apparently leads to nothing you may suddenly find your reward.

12726. It might not have been unreasonable in Adam, but since his day there has been a very long experience of winter-sown crops?—There has been a long experience of winter crops, but what I mean is, that a man has got no business to say that because the crop has not yet come last winter's sowing has failed.

12727. It would have been an unreasonable thing in Adam?—I agree with you; but, if I may say so, I should use that in my favour; because I should say that if you look at any science you will find that theoretical investigation has always led ultimately to practical power. I could give examples in industries, but they will occur to most of those present. Investigations which have been purely scientific have almost always led to practical results, because the knowledge has been able to be used, and it has produced great results. So that, just as since Adam, we have had great experience in winter sowing, so I should say that since the days of Bacon or Newton we have had great experience in this—that you never can have an increase of knowledge in any subject bearing on practical life without its leading to increased practical power.

I want now to deal with the justification of the use of the experimental method by what it has actually performed, and I am going to ask you to allow me to confine myself to the work of the last 40 years, because that is the period which has fallen under my direct notice. I shall group it in the way I group it in my own mind in order to make out this justification. As I have said, to my mind this direct appeal to practical results is not necessary, though it is immensely helpful, to enable one to make up one's mind as to what is the right course to pursue; but it is all important in dealing with the many well-meaning persons who do not go along with me in their views with regard to it. The difference is not, I think, because there is a difference of fundamental principle—they are as loyal, probably, according to their lights, to the doctrine that we ought to do our best to lessen suffering as I am; but they have to learn that which scientific training easily teaches those who have had much to do with it, that the right way to do so is to make full use of the experimental method. I wish, therefore, to take the results of experimental work in the last 40 years, and point out how it has removed ignorance—that is to say, how it has given us knowledge and how that knowledge has become of practical value in reducing suffering.

12728. If you please?—Of course the first example which one must take is that of sepsis and the antiseptic method. If you look at the books of 40 years ago you find that the idea that sepsis in the case of open wounds was due to organisms derived from outside, was rarely held; I doubt whether it was held by any, it was certainly held by very few, and it was not put into practice in any way. And the work of those who demonstrated that sepsis was in all cases due to organisms, and where access was possible, it was almost always due to organisms coming from outside the animal attacked, gave rise to the antiseptic treatment, the value of which it is quite unnecessary

to dwell upon. It was purely the result of experimental research, and it is a triumph the practical value of which puts it at the head of all the changes in the last 40 years. But I am not going to deal with that any further than just to refer to it, because I am sure that its value and its origin are present to the mind of everyone here.

I wish chiefly to deal with the case of microbic diseases, which for reasons that will appear, I shall divide into infectious diseases and diseases communicable otherwise than by what is ordinarily called infection. If you go back 40 years you will find that these diseases were complete mysteries; they were, alas! recognised as facts, because they could not be otherwise; they were ever present with us. They were known as things which ran through a certain course, their symptoms were studied, and the doctors of that time did their best to alleviate them, no doubt, by nursing and treatment. A great number, no doubt, tried to do so also by drugs, which, I think, most authorities to-day would say were practically of little use. But the diseases themselves were, so far as their causation is concerned, perfect mysteries. Now experiment has changed that from top to bottom. The bulk of these diseases are known now to be the result of an invasion of the system by specific organisms which multiply in the system, and the disease is due to the presence and action of these foreign organisms. In fact, I do not think that I should be giving an incorrect idea of the result of the work of these 40 years if I was to say that it has revealed the fact that we live not as isolated living organisms, but that we are surrounded by and penetrated by infinitely small living things of very varied descriptions—that we are, as it were, bathed within and without in a sea of microbic life; I am using the word microbic in its broadest sense. Within us we have them permanently and probably normally; in fact, if you include the organisms which live in the blood, certainly normally. We are surrounded by them, and instead of diseases of this kind having to be looked at as due to defects or failure in normal action in the organism itself, we have grown to realise that they are the result of attacks upon the organisms by external foes.

12729. Do you regard all this state of things which you have been describing as wholly due to experiments on animals?—Absolutely. It is absolutely due to them.

12730. We have had a good deal of evidence from other witnesses on the subject, and we need not trouble you to describe the instances?—Quite so. It is difficult for me to say which is the earliest case in which this was established; but I will take one of them, because I wish to show how baseless is the idea that the work which has been done in this respect is work which has only led to doubtful or hypothetical results. I wish to show the actual and certain advance of knowledge. Then I wish to show next the way in which that is due to experimental methods. Then I wish to show the practical methods to which it has led. I will take a single example—any one will do—but I will take the example of anthrax. When Pasteur took up anthrax, it was only known as a terrible disease among cattle, leading to a vast proportion of deaths. He ascertained that it was due to an invasion of a particular microbe, which is known as the microbe of anthrax, which multiplied with infinite rapidity, and which ultimately led to the death of the animal. He then found out a method of inoculation (I am not going to deal with the details of his method for a moment) against it, and in the classical experiment to which I have referred, he exposed to anthrax the 25 sheep which were inoculated, and the 25 which were not inoculated. He might have done it by putting them in company with diseased animals. As a matter of fact, he took the severer test of deliberately inoculating them with the disease. The result was that those which were treated with his process did not die, and the others did. Now, that is a scientific result as certain as the action of nitric acid would be on iron; I mean that it was a definite experiment, capable of being repeated, and showing conclusively that there was a way of defeating this disease, a way which might, or might not, be availed of by mankind, according as the importance of warding off the disease was great or was not. There was nothing hypothetical in it; it was a fact which was just as much demonstrated as any fact that has been demonstrated in chemistry or in any other science. I have there taken a case which relates solely to animals. I have not approached the question of the applicability of the process to mankind, because, fortunately, anthrax is very rare among mankind. But if you confine yourself to the consideration of it as a disease of animals, you see the advance that has been made. First of all, there is the knowledge of the cause—that is to say, that it is due to the presence of microbes. Then (as I shall presently point out) the fact that it was due to the presence of microbes led to the discovery of the method of combating it; and that led to the practical application of that method, and, if you choose to avail yourself of that method, the disease is conquered. The whole is based upon the discovery of the origin of the disease. It was the knowledge that it was due to microbes which led to the whole of that discovery. Persons might say: "What good does it do to mankind to know that this which they call a disease is really a consequence of a particular type of small life which has got into the organism and multiplies there? It does not alter the nature of the disease; people die of it all the same." And you would think that the pure theoretical knowledge that it was due to this particular cause left the practical problem where it was. May I point out how that piece of knowledge did not leave the problem where it was, but put it in a totally different position, and necessarily led to its solution? You can see it in this way. It instantly put the phenomenon of recovery in a new position. When an animal was healthy, and there were only a few microbes put in it, when you would say it was best calculated to repel invasion, they multiplied furiously. At the moment when it was weakest, when the microbes were strongest, most numerous, and the animal was most exhausted (if it was a case of recovery), the tide turned, and the enfeebled organism was able to fight the strengthened assailants successfully. That necessarily led to the conclusion that there must have been a change in the organism during that period, which entirely altered the relative strength of the two forces; and that was the beginning of the realisation that in these diseases there comes some protective change in the organism that is attacked which brings recovery at the time when you would least expect it. This led to the inquiry: What is that change? It must be something that survives the disease, because we know that when a man is recovering from an infectious disease, he can give it to other people. Yet, although he is more exposed to infection from himself than any other person could possibly be, he is not infected. Therefore it must be something that survives the disease. Then the question came: If it survives the disease, is it possible to produce it under circumstances so that it may be present in the organism independently of the disease? In fact, men came to realise that recovery in a case of microbic disease means the "turn of the tide" in a process where, on the one hand, the invading microbes are multiplying, and on the other hand these protective forces are multiplying, and recovery or death means whether the turn of the tide comes too late or not. The moment you see that that is so, the whole question becomes—Can you antedate this turn of the tide? Can you contrive that this protective condition shall be produced earlier, before the mischief is done? It is no use putting a fire out when all that is valuable in the house is burnt. From these ideas there sprung almost immediately the two main methods of treatment. The one seeks to produce this protective state during the period of the disease, and it is a treatment of this type which succeeded in rabies; the other seeks to produce the protective state before the disease comes, and is the method that was illustrated in anthrax. Finally, they led to the third line of discovery. Is it possible to get the protective substance from somewhere else, and introduce it during the disease, in order to antedate the time when the system will become strong enough to repel the attacks of these foreign invaders? Now, if you think of all those three lines of discovery which have respectively led up to the treatment of rabies, to the prophylactic methods which are used in the case of anthrax, pneumonia, and other diseases, and to the serum treatment of diphtheria, you will find that they all came from the knowledge that the cause of the disease was a foreign organism, capable of multiplication, and that Nature defeated it by a change in the organism which made it more capable of resisting. These practical applications were the direct outcome of those two facts, which were pure pieces of scientific knowledge. So long as the disease was considered merely as a disease which ran its course, which was due to an unknown cause, whose consequences were only known by its

Sir J. F. Moulton.

24 July 1907.

symptoms, no one of those things could possibly be discovered. Their discovery was solely due to the experimental examination of natural processes. I was much amused by some evidence given by one of the lady witnesses who have given evidence before you. She seemed to be very much disgusted with the consequences of all this knowledge, and, if I might paraphrase what she said, it was "Nature has made such nice drugs and put them in the plants all around us. Why should we not use these, and not go to such messy things as serum?" Those are not her words, but they express the effect of them. Nature has put all kinds of useful drugs in plants, but she never dreams of using them for curative purposes. Her method of curing is entirely by means of the messy things with which the researches of the last 40 years have led us to work. We are now, thanks to the theoretical knowledge that we have acquired of the cause of these diseases, working to help Nature along the very lines which she has from the foundation of the world herself taken in fighting these diseases; and therefore, in my opinion, if we are to be guided in our action by our respect for what Nature has so kindly done for us, our course would be to pay very little attention to drugs and to pay very much attention to those lines of treatment which are based on the study of the two closely analogous phenomena of recovery and immunity.

12731. Assisting our natural friends in fighting our natural enemies inside us?—Yes, fighting our natural enemies by those means which, in the cases in which we do beat them, are the weapons which we use.

12732. (*Chairman.*) I think you were going to deal with the question of the influence of experiment on communicable disease?—I have been pointing out that the whole modern conception of the nature of these diseases and the mode of their cure arise from discoveries which have been arrived at purely by experimental methods, including necessarily experiments on living animals, namely, the discovery that they were due to foreign organisms that entered and multiplied in the system, and the discovery that the changes in the system which unquestionably produce recovery are closely allied to those which also produce immunity after recovery. So far I have only spoken of our attempts to effect a cure by introducing those protective substances which Nature, when there is need, produces in some strange manner. But it looks at this present moment as if we were going to combat some microbic diseases still more successfully by stimulating other agencies by which she effects her cure. I do not know whether Sir Almroth Wright is to give evidence before this Commission, but if so he will point out how he has devised a method of stimulating the action whereby the white blood corpuscles actually destroy physically the organisms themselves, so that we are gradually utilising both of Nature's methods of cure (and utilising them exactly as Nature does) for the purpose of antedating what I have called the turn of the tide, that is, strengthening the resistance of the organism that is attacked more than Nature would do merely by her methods of reaction. I now want to pass from these to another class of diseases in which equally we have been studying during the last forty years the cause of the disease and its action on the organism, but where research has led to a totally different method of fighting them—I refer to the communicable diseases which cannot be called infectious. Take the case of malaria, the tsetse in animals, and Malta fever.

12733. And rabies?—Rabies belong to the first set, because we fight it by generating in the body a protective substance. The way in which we fight it is, we have got a method of giving an attack of rabies which is very quick but very slight, and the consequence is that it produces very swiftly a small amount of protective substances. We then give another one which is also quick, but is stronger, but which can be borne by reason of the presence of the protective substance, and continue doing so while the main body of the attack is moving up. We have thus gradually accumulated a body of protective material, which, when the main attack comes, which would have been inevitably fatal, enables the system to resist it.

12734. I merely thought that the gnat was serving the same purpose and function that the mad dog was; therefore I thought it was really in the same class of disease?—May I apologise. You are quite right. It is not infectious but is communicable in a different way, and ought to be in the second class. The reason I already mentioned it with the first class was because we there use the method of cure of which I have spoken—that is to say, we attempt to produce a protective substance. It was I that was wrong. I want now to pass to cases where we cannot imitate the method of cure, but because we know the cause of the disease and its method of communication we are able to intercept it. Take the case of malaria. I do not know that our methods of curing malaria have advanced substantially, but we now know the cause of malaria, and we are destroying the possibility of communication. The work that has been done at Ismailia is an example of this. They have got rid almost entirely of the mosquito, which communicates the disease by its bite, and have thus almost got rid of the disease.

12735. Would you say that that was discovered by experiments on animals?—Certainly. They had first to discover in what way this disease was communicated. As soon as they had discovered in what way it was communicated, the destruction of the communicating animal presented itself at once as a method of preventing the disease. A similar case is that of the tsetse, which is absolutely fatal to cows in districts where the tsetse fly is found. They find that it inoculates an organism which produces death. I do not think they have made any advances in fighting the disease when the disease is once communicated; but knowing that it is communicated in that way, our attention is at once turned to discovering how one can fight the tsetse fly, or how one can prevent the tsetse fly itself getting the organism into it which it passes into the animal that it bites. In certain places in England, where there used to be ague, ague is now stopped. It is quite possible that that ague was communicated by the bite of an insect that derived the organism which is the cause of ague from biting some affected animal. We have drained the country; the insect probably exists, but in far smaller numbers, and there are fewer people there, if any, who are affected with ague from whom it can get the infection. The consequence is that the insect is harmless, because it cannot communicate the poison, or rather the poisoning organism, because it cannot get it. And, similarly, we can, when we know the cause of the disease, set to work to prevent the occurrence of those circumstances which enable it to be communicated. This is now being done with yellow fever and many other diseases. It may be that the disease is so bad that the only method we have of fighting its spread is to kill the animal. Take the case of glanders. Now that we thoroughly understand what glanders are, when we thoroughly understand the method of testing whether an animal is suffering from glanders, the animal may be killed at once, and that stops the propagation of the disease. Without that knowledge we could not ascertain so soon what animals we ought to kill, and they would be left as centres of contagion. So that it may be equally effective from the point of practical utility whether we find out the means of communication and stop it, or whether we attack the disease when it is communicated. In both cases it is the knowledge of the cause of the disease and the knowledge of the way that that cause comes to operate on the organism which enable us to devise these practical methods. And all that knowledge has been derived entirely from research work, conducted for the purpose of acquiring knowledge, and from the knowledge has come the power. I do not suppose the investigation of the cause of these diseases was carried on upon the lines of any direct idea of a protective method, but the object was to find out the real nature and operation of that against which protection was necessary. When this is done, the step to practical utility always comes sooner or later.

I have been dealing thus far with the cases of disease. I will now turn to another matter which I see has formed the subject of a great deal of evidence, and that is the study of the organism on which these diseases operate. A vast amount of experimental work of the last forty years has been directed to discover the physiological actions which are going on in man. Mere anatomy, mere structure, will not tell you physiological action; the knowledge of physiological actions must be obtained by experiment from a living creature, because as a rule as soon as death comes they cease. The importance of this work is just as great as is the importance of the investigation of the causes of disease. Take, as an example, that which I see has been the subject of evidence before this Commission—the localisation of function in the brain—the discovery from the sypmtoms of paralysis, or epilepsy, of the place where the interference with the

nervous system is taking place. It would be quite impossible to ascertain the laws which govern this excepting by experiments on a working animal—that is to say, a living animal. In many cases it need not be a sentient animal; the experiments may be done when consciousness has ceased; but it is absolutely imposible to ascertain them unless you make experiments on an animal that is still living. But there are similarly important experiments which go to blood pressure, to digestion, to the function of the great organs, such as the liver, or the pancreas, or the kidney, or the suprarenal capsules, in which it may be necessary to trace out consequences which do not occur immediately. In that case you must perform them on animals which are not only living at the time of the experiment but which are allowed to live afterwards. The examples which have been given you, I submit, show how all-important such investigations are for several reasons. One of the reasons is that without the knowledge so acquired you cannot read causes from symptoms. I should define the great change between curative science, as it exists now, and curative science as it used to exist many years ago, as being that now we try to fight causes, and then they only tried, or mainly tried, to fight symptoms. Fighting symptoms may be an extremely dangerous thing. A man who, not knowing anything about an engine and finding an overdriven boiler blow off, should fight the symptoms by screwing down the safety valve, would come to serious trouble. And in the same way, if in the case of a symptom—say the symptom of the rise of temperature going up—you say, the disease makes the temperature go up; very well, then, we will help the organism by putting it down. You may get into serious trouble supposing it should turn out that the rise of temperature, by lessening the resistance to the circulation, eases the heart and makes its work less onerous; it may be that the fast-beating heart has been able to do its work without injury only because the temperature has risen and its work is lighter. If, now, you put the temperature down without removing the cause of fast-beating, it may be that you overstrain the heart—do mischief just as the man who screws down the safety valve. I am not saying that this is so. That is not a matter on which I can speak. All I want to point out is that it is only by intimate knowledge of the organism that we know how far it is safe to fight symptoms. But, more than that, it is only by such intimate knowledge that we are able to diagnose causes. You get a headache; it is a mere symptom which may come from many different causes. Unless we have perfect knowledge of the organism we may imagine that a thing which has been successful for one headache is useful for another, whereas it may positively aggravate it instead of doing it good. The aim of all this investigation into physiological action, which is so varied in its character, and relates to every different part of the organism, is to put the medical man of to-day in the position of a man who knows the construction and operation of the engine he is working, who knows what is the meaning of every symptom of irregular action; and the increase of his power of alleviating suffering and staving off death is enormously increased by this increase of his knowledge and power of diagnosing which has arisen from these experimental researches. As I have said, these experiments must be experiments carried on upon living animals, because their object is to ascertain what is the mode of working of each particular organ, and what is the effect of any particular interference with that organ. Sometimes these experiments have resulted in curative methods. You could not have a better example than that which was put before the Commission, namely, the relation of the thyroid gland to myxœdema, and cretinism, where, I think, to the surprise of everybody, it was discovered that we have glands within us which are producing protective substances for the normal life, just as nature will, when there is an attack of a microbic disease, produce *pro hâc vice*, a protective substance against the foreign invader. When you take away the thyroid gland, and there is not this protective substance, which is no longer formed, then you find the body gets out of order because that is no longer present which was necessary in order to keep down the inherent forces of dissolution. Then it was discovered that, if you supplied artificially that which this gland produced, you could keep down this form of disease just in the same way as you can stop the effects of diphtheria, if you put in from another animal that which nature would produce in order to repel the microbic attack. Just as in diphtheria you get recovery, so you find in myxœdema that when you supply this substance which the body has ceased to have the power of producing, you get the remarkable discovery. And this appears to be only the commencement of a series of analogous successes. But, apart from the question of direct curative methods so arrived at, the power of diminishing suffering that is given through increased knowledge of the organism is so great that it is difficult to over-estimate it. I do not think it is necessary to give further instances to this Commission. I only want to put those forward to show that there is abundant justification for saying that knowledge which, from its very nature, must be obtained by experiment has already been of the very widest benefit to mankind. I will go on to the question of whether experiment is permissible for the purpose of acquiring such knowledge. Here I must go back for one moment to the example which I gave, as a typical one, of preventing plague getting into a town by killing all the animals which could convey it. In my view, we are just as much bound to prevent suffering due to ignorance, and just as much justified in inflicting such pain as is necessary for the purpose of doing so, as we should be in killing noxious animals. I have pointed out that this necessary knowledge has in the past been and must be obtained by experiment. It must be done by experiment, it can only be done by experiment on men or by experiment on animals. I unhesitatingly say that our right to experiment on men is extremely limited. In the first place, we have no right, voluntarily, to allow death to occur, even though the man would be willing to permit it. Nor do I think we have any right, voluntarily, to allow serious damage to occur, unless it perhaps may be where it is directly for the purpose of saving life. So I do not think, in view of mankind's power of anticipation, of memory, and the possibility of future suffering, we ought to take the responsibility of allowing experiments which might produce serious consequences to be made on man. Let me give an example. I do not think that we should have the right for experimental purposes to allow a man to infect himself under special circumstances, even though they would assist science, with a disease like syphilis, in order to add to knowledge. It is too serious a responsibility to take to allow that to be done, considering that that man will live for years afterwards, and cannot divest himself from social relations.

12736. Supposing he was sacrificing himself in that way, and by his sacrifice he could make probable the saving of a great many lives in future, why should you prevent him on the principle that you have to look forward to ultimate results of torture or sacrifice?—Well, it should be the last resource. But I will tell you what, in my opinion, I think constitutes the real difference. I do not think that you ought to lessen in any way the feeling of sanctity of human life, because the consequences are so very wide-spread. To let a man, in a moment of enthusiasm, do a thing which might, or perhaps must, have permanent evil effects throughout all his life, approaches, in my mind, very close to an infringement of the great principles which make us refuse to consider whether it would be a benefit that one man's life should be taken. Everyone of us knows men whom it would be a blessing to mankind to remove, whose lives are a curse to those around them, but, however much we feel that this is the case, we do not allow ourselves to act upon it, because if we were once to commence to act in that way towards men, the consequences that would follow would be so far-reaching that we have found it best to lay it down as a rule that it has been, except in special cases prescribed by law, not permissible under any circumstances for an individual to take human life or to permit a man to die if he can prevent it; and you will find that doctors will not only work as hard for a bad man as they would for a good man, but they will actually bring a man back from the doors of death, although they know that he is going to be hung for what he has done; because we find it is absolutely necessary to take as an unchallengeable principle that human life is sacred. Therefore I think that although in small matters you may use experiment on man, and for the very last stage of experiment you probably must do so, you ought to stop there.

12737. (*Sir Mackenzie Chalmers.*) You mean with the consent of the man himself?—Yes, even with the consent of the man himself. Where you have established a well-founded scientific probability that the thing is

Sir J. F. Moulton.

24 July 1907.

safe, then I think you are justified, but before you attempt to experiment on man you must have done everything to prepare for it, and you must know with fair scientific certainty what will happen. And that is the reason why I do not think that experiments on man are to be considered at all when you are thinking of the enormous amount of work that has to be done in scientific research. The necessary work must be done otherwise. Now, I turn to the question of whether we should use animals for the purpose of research. In my opinion, unquestionably, it is not only permitted to us, but it is our duty to try to remove ignorance by, if necessary, experiments on animals; and I want to give the Commission the principal reasons which make me have such a confident opinion on this point. The first reason is the overwhelming preponderance of the prevention of suffering by this method. The great bulk of the necessary experiments, as you know, can be made without any pain to the animals at all, because the animal never need be conscious, and therefore no pain is caused at all. But taking the others, the amount of experiment, if properly done, which causes pain is incredibly small compared with the results of the knowledge obtained, even if they be measured by what has already been achieved. Just look at the complete change that there is on our knowledge of all those great groups of diseases which I have called infectious or communicable. We are no longer fighting them blindly; we are no longer striking in the dark; we know what they are. This very knowledge enables us to avail ourselves of experiments which are not painful for the purpose of assisting us in the task, and every man who feels his responsibility does all he can without occasioning pain. But what is done is done with a knowledge of the enemy we are fighting, so that the experiments grow more telling. The number of painful experiments, as is shown by looking at the actual experiments which have been made, is quite infinitesimal. I read the description of the experiments done under licence in England, where excellent research work is done, and most carefully done too; I read through the list of those which were thus done in a year, and I very much doubt whether the total amount of suffering caused by those experiments would be much greater than would be caused in a single fairly large shooting party, where there were one or two bad shots. If you consider the amount of suffering that is caused in the world, not only thoughtlessly, but even deliberately done by people who are ordinary normal men, and may be able to show a reasonable defence for what they do, it dwarfs so utterly the amount that is requisite to produce this useful knowledge that if the matter was not so serious it would be almost ludicrous to think that there was this organised opposition to the pain caused in scientific research in proper hands. Why, what is attacked here is the only bit of fruitful pain in the world. The greater part of pain had better not be. A man suffers and dies, or suffers and gets well, and all the pain he has suffered has benefited nobody. And in the case of animals there is all this vast mass of pain which is inflicted or permitted, and people tolerate it and say nothing about it, and look upon it as an ordinary thing; but there is one little bit which brings return in lessening the sufferings of the world, and the people are to be found to organise themselves against it, and throw the whole of their strength into denouncing and preventing it. In my opinion, if you look at the medical science of to-day and the medical science of 40 years ago, and realise that the advance has been caused by physiological research, which is largely carried on under the very Acts which restrict, which regulate, but which distinctly permit painful experiments, and then consider on the one hand how much pain that has caused and how completely it has changed our power of dealing with disease and of alleviating suffering, it is really incomprehensible that anybody who sees the totality of misery in the world should think that the small amount of pain that has produced that gigantic result is the first that ought to be stopped. That brings me to the next point, and that is this. Mankind not only claims, but perpetually exercises and properly exercises the right to cause or permit suffering in animals when needful or desirable. It requires considerable thought to realise the extent to which that is admitted by all, and is, indeed, unchallengeable. Take the case which I gave of the rats on board the ship. I pointed out that it was right to kill those rats in order to prevent the possibility of their spreading the plague, but no such serious reason is necessary to justify killing them. I do not suppose there is anyone who would challenge the right of the captain to do it if they would injure the cargo, if they would produce a small pecuniary loss under these circumstances it would be considered that it was perfectly right for him to do it. We unhesitatingly kill vermin—we kill things that do pecuniary harm, and no one dreams that it is a thing which a man of high principle will not do. So that nobody ever dreams of questioning the right of causing pain for the purpose of a useful result, when that useful result is merely pecuniary. But when instead of the result being pecuniary, it means diminishing the suffering of the world for all time and for all the world, forsooth, it is challenged. Take the case, for instance, of a herd of cattle attacked by some painful disease, from which, we will say, 50 per cent. of those attacked survive. A man would be considered perfectly justified in allowing them all to go through the disease. The 50 per cent. that would die would die, the rest would have the pain of the disease and get better; and he would say, "Well, but I could not afford to sacrifice the 50 per cent. that would survive—it would be too big a loss to me." For the £10 apiece that they were worth he would have permitted them to be killed on the spot; but he considers that he has a just and perfect right to allow them to suffer all that pain in order to save himself from the loss of the 50 per cent. that survive. And I do not say he is wrong, because the comfort of his family and other things of importance to him may depend upon the question of how great is the loss inflicted on him pecuniarily by this attack. But if it is allowable to permit the whole of that suffering in the form of in order to avoid a pecuniary loss, the question as to whether it is right to increase by a little the suffering by well-designed scientific experiment to secure a return, not in money, but in the power of stopping suffering, seems to me literally to permit of only one answer. No man could consider the matter without realising that such infliction of pain was justified if he would do what I hold he ought to do: add inflicted and preventible pain together. The moment you take as your guiding principle that you are responsible for pain which you could prevent, and that this and the pain which you inflict must be taken together in order to guide your action, it appears to me that there is no painful treatment of animals which is nearly so completely justified as that which leads to knowledge. Nobody, so far as I know, would hesitate to overdrive a horse in order to save a life or to bring assistance to a life that was in danger, and yet that would be suffering inflicted for the purpose of benefit to a single individual. The people that are engaged in scientific research are working for something which will benefit not one single individual, but will benefit the race for all time.

I feel myself that the justification for the necessary use of even painful experiments, where they are required for the purpose of obtaining knowledge, can only be questioned by shutting the eyes to the further consequences of our action—putting a veil between our action and what it ultimately leads to. And I cannot help thinking that the people who lead the movement on the other side must be aware of this, because they deal so persistently in misrepresentation. It is very easy to misrepresent the work of those who are a long distance in advance from the ordinary man. I have known this illustrated again and again in manufacture. Processes have been stigmatised as adulteration, as falsification, and everything that was bad, whereas if people had followed out the advance of science they would have known that they were simply better methods for doing the same thing as earlier processes, and doing it with greater certainty and with greater cheapness. But they had not followed it out, and because the new processes were different, a contrast to the old ways, and people thought that therefore they were something to be stigmatised, so it is here. If we could get people to learn what science is and what it has done, they would never attack those who are at work on it. And it is to keep them from learning that there is this frightful misrepresentation. I remember, and I think the Chairman of the Commission probably remembers, how in the seventies the walls of London were placarded with a poster representing a rabbit in the process of being roasted alive.

12738. (*Chairman.*) I do not remember it, but we have been reminded of it; we have heard about the

roasted rabbit ?—I remember it well, because I wrote about it to the late Sir Michael Foster, and I asked him, What is the lethal temperature; because I recognised at once that the experiment which was thus misrepresented must have been one to find out when temperature alone would suffice to occasion death.

12739. You may take it for granted that we know all about it; we have had it explained by Sir Lauder Brunton ?—Very well. It turned out that the temperature was something like 109 or 111 degrees.

12740. (*Sir Mackenzie Chalmers.*) 114, to be exact ?—It differs very much, of course, in different animals.

12741. (*Chairman.*) That was the outside temperature, not the blood temperature ?—I was giving the temperature of the blood. Anyone would realise, of course, that the object was to do it under such circumstances that no reaction should be set up—that there was simply an increase of temperature, and that therefore there must be no disturbance of the organism, and that the poster was absolutely false. Yet that placard was all over London. It is not surprising that a great number of people join this organisation, because they get their ideas from these very serious misrepresentations. They believe themselves to be humane, but when one realises the evil that ignorance does, and that the only way in which ignorance can be removed is by the experimental method, and the enormous advantages in the way of saving pain that these results have produced, one must feel that the truly humane men are the people who are defending scientific research.

Now I should like to turn to the practical conclusions to which I have come with regard to this subject. You see that the good basis of all these movements is the desire of saving pain in animals and men. Now if that is so, the whole motive ceases with the conscious life of the animal. As soon as it has finally passed out of the conscious life the whole *ratio agendi* ceases. It is absurd to object to an experiment on an animal that has ceased to be conscious and will never again be conscious as it would be to object to the dissection of a dead animal. The only motive is the desire to save suffering, and suffering then is as impossible as if death had actually occurred. Now what is the consequence of that ? Hence there ought to be no interference with experiments on animals which are in anæsthesia, except that they should be permitted only to persons who can and will take care that the anæsthesia is complete, and that the animal is killed before it comes out. There is no other principle on which any interference could justifiably take place. There must be somebody in charge of or superintending the experiment who, from his character and position, can be trusted with the responsibility of seeing that there is what I may call permanent and effective anæsthesia. Therefore, with regard to such experiments, it is not only not necessary to interfere with their being used for educational purposes, but if the Commission may trust my experience they will indicate that in their opinon it is most important that they should be so used. For there is no comparison between the living effect of an experiment that you have seen and one that you have merely read of. May I give my own experience ? I have many and many a time read over carefully-described processes, and have imagined that I understood them; but I knew of old what that meant, and used generally, in cases of any difficulty, to insist on what we call "having a view." I used to go down and insist on being taken, not necessarily by an educated person—I much preferred a workman—right through the whole process, and seeing it done before my eyes. I went back with a knowledge of the case, with a power of handling it, and with a power of drawing conclusions as to the processes which were quite new-born. So it is with the man whom you are educating for this serious duty of fighting disease. If he has actually seen an experiment, it lives in his memory. But that is not the only thing—it remains in his memory as a living thing, and when he acquires new experience or new knowledge connected with it, he will find that it will make the old experiment mean more than it did to him even at the moment when he saw it; because he sees the whole thing before his mind's eye, and not only reads a description which, after all, only states certain results. And, as there is no ground, therefore, from the side of humanity to interfere with these experiments which cause no pain, I think they should be largely used educationally. Medical education is of prime importance to the community. The greatest difficulty in the way of giving to the world the full benefit of all the accumulated knowledge of this last 40 years is that you have to educate your practical men up to the level of it. Just as in war it is of no use having medical appliances at the base if you cannot get them up to the front of the army, so it is of no use to have this accumulated knowledge unless the power of using it to prevent suffering is in the hands of those whom you train. Therefore the efficacy of our methods of tuition ought not to be looked upon as a matter of little importance—it is a matter of the very gravest importance; and I should put no restrictions upon the use of painless experiments in connection with it, excepting that the experiments must be under the supervision of someone possessing a certificate such as I have indicated, which should be a certificate granted to persons who could be trusted with regard to anæsthesia. And, whether you have reports of those experiments or not I do not think is of the slightest importance, provided it is thoroughly understood that it is the duty of those possessing the certificates to see that the anæsthesia never ceases, and they are held responsible for so doing.

Sir J. F. Moulton.
24 July 1907.

I turn now to the more difficult question, a question which require more careful examination—namely, that of experiments that are in themselves painful. There, I think, you should divide the certificates into two classes. Certain men of acknowledged capacity in research, who have shown that they are not only capable of serious research, but have already done it, should have general certificates entitling them to perform such experiments, subject only to one thing, and that is that they should report fully every experiment. They are immeasurably better able to judge what is worth doing than any body of men that you could put over them. They are the people who are working at the subject itself, and they are, as a rule, men of such high position and high character in England that there can be no ground for being afraid of trusting them with this power. But I am satisfied that, both for the satisfaction of those who desire to proceed cautiously and for the good of mankind and also to prevent any possible abuse, they ought to report all that they have done. I do not think that a painful experiment should be allowed to pass into oblivion. It is made, in my opinion, for the benefit of the race and for the increase of knowledge; therefore I think such reports should be made, and I do not think that anybody concerned would really object to that being done.

12742. Do you mean that that report should be made by the inspector or by the operator ?—By the operator.

12743. Sent into the Home Office ?—Sent into the Home Office. I think he ought to do that. I would put him under no restriction as to the character of his experiments; I would not put him under any restriction as to the place in which they are done; but I would have a full report sent into the Home Office. Of course, a certificate of that kind would be given only in recognition of an acquired position and high worth in research. You can only do harm by interfering with men of that class. There is no danger of such men developing recklessness. I have not examined anything excepting the experiments that have been done in England, and I am therefore speaking only with regard to them. I have never, in the years that I have followed the matter, found anything which from this point of view I call recklessness of suffering in any experiment made for research.

12744. Have you found levity ? We have heard accusations of levity on the part of those who see experiments ?—I feel very strongly that such an accusation is unfair even in the case of students. I do not find that the medical student of to-day is a man of the Bob Sawyer type. I think they work extremely hard. Those who see them in their classes can give you better information on this point, but certainly those I have come across are hard workers and are not guilty of any levity.

12745. (*Mr. Ram.*) Would you have any inspection of these experiments ?—I would have no inspection of the first-class certificates.

12746. (*Chairman.*) You do not mean the first-class certificates described in the Act ?—No; I mean my first class. Just let me give an example. Supposing it was a question of giving a general certificate to Sir Lauder Brunton. The idea of controlling what he

Sir J. F. Moulton.

24 July 1907.

should do with it would, in my opinion, be nothing but a blunder. But he would have to report all that he did; and if, by some accident, a mistake was made in any case, if a person developed levity, or even recklessness or cruelty, his reports would show it, and his certificate might be withdrawn by reason of it. He might then be relegated to the second class, which I am going to describe.

12747. (*Sir Mackenzie Chalmers.*) How do you suggest that a man should get into the first class? You are imposing a new duty upon the Home Office?—I know it.

12748. (*Chairman.*) You begin by supposing that he is a first-class man?—Yes. I am quite prepared to say how I think the Home Office ought to decide. I think it ought to decide by the opinion of the leaders of the medical sciences, because I am satisfied that they possess, to an equal degree with any other body of men in the world, the moral qualities necessary to enable them to advise; and beyond question they possess, better than anybody else, the intellectual qualities and the qualities of knowledge which would enable them to do so efficiently; and a certificate of this kind should only be given where there was a consensus among the advisory body that the person held such a position in medical science that he might have this general certificate. I now pass to those who have not attained to that position—which, as I have said, would be an exceptional position, although I am happy to say that there are many men in England who would merit it. I think that in the case of younger men or men who had not yet attained to the commanding position of those to whom I would give this general certificate the lines of the present Act are the right lines. I think it is reasonable to expect them to accept specific limitation of the type of experiment, of the scope of the research, and of the place where the experiment is to be performed, in order that there might be the security of the supervision of those who are over the laboratory, if there be any such persons, and also the security of inspection. Limitation of this kind, which the people would be bound to respect, and I believe would respect, should prevent all danger of abuse, which, though I think it would rarely become a reality, is more possible to occur than it would be in the case of the exceptional men to whom I have before referred. I see no reason why those restrictions should not be put on; and, as before, full and complete reports should always be made, so that a record of all these experiments and their results should be preserved. The line, then, that I should advise, would be as follows:—Certificates with regard to non-painful experiments—that is to say, experiments where the animal was kept under anæsthetics and not allowed to survive—should be quite general, but should only be issued to persons who would perform or supervise those experiments, and could be trusted to see that the anæsthesia was complete and permanent. For painful experiments there should be a small but select class who should have general certificates. The other class should have special certificates, specifying the nature of the research, the nature of the experiment, and the place where it was to be done; and there should be full and adequate inspection of those places while the experiments were going on.

12749. Strangers you would not have present, I understand?—I would not have strangers present, first of all, because, in my opinion, it would not assist the experiment, and, secondly, I do not think it would be a good thing for unqualified persons to see these things. They are the serious work of research, and persons who are not trained by medical or physiological study would gain no good from witnessing them. But I would encourage students being associated with this research. It is the finest training that they can have. So far as it can be done without interfering with research work it is a mistake to keep people out who are capable of learning from it; but that the public should be admitted would, I think, be a still greater mistake. In my opinion, they have no business there, and it is much better to exclude them wholly.

12750. (*Sir Mackenzie Chalmers.*) You mean that the public would go there in the same spirit that the public used to go to an execution?—Exactly. Now I hope that I shall be forgiven if I say one or two words about the two restrictions which have been recently suggested to the Home Office.

12751. (*Chairman.*) Yes, we should like to hear your suggestion about that?—I thoroughly disapprove of them. The first relates to foreign savants who are not naturalised Englishmen. There is no possible reason why they should be put at a disadvantage as compared with British subjects. Of course, for the first class of certificates under the system recommended they must have a recommendation from English people of the proper position to show that they deserved the privilege; but I am not talking about that for the moment. I am talking about the existing system. Foreign universities and foreign men of science have been extremely good to our students. They permit them to take part in their courses; they permit them to use their laboratories, and without good reason I would not show any want of reciprocal kindness towards foreigners. No reason is put forward for thus placing them at a disadvantage, if they possess the qualifications which would justify the certificate being granted to an Englishman, excepting that it is suggested that you cannot enforce the performance of the conditions. That is quite a mistake. The only difficulty in the way of enforcing the performance of the conditions is that they are capable of changing their residence; but an Englishman who wants to break the conditions is equally capable of changing his residence. The true remedy in both those cases is to have a responsible head of the laboratory, who has to see that the conditions are duly performed step by step as the work goes on, and, in my opinion, there would be no greater difficulty in ensuring this being done in the case of a foreigner than there would be in the case of an Englishman.

12752. That would be so in the case of a foreign doctor working in an English laboratory; but, supposing that he wanted a laboratory of his own, and hired a laboratory of his own, and started it for the work for a year in England, would you have a superviser over him then?—I think you might quite fairly require that there should be some person, resident in England, responsible for the observance of the conditions—that there should be somebody, such as the head of the laboratory, to whom Government can look to see that the conditions are performed, not in a lump, but *pari passu* with the work done. You are justified in recognising a difference in the case of foreigners to that extent, but no further.

12753. Do you not think that if he took a laboratory by the year, we will say, the country has got just as much hold upon him as upon any Englishman who took it?—Yes. There are a great many foreigners in England who should be trusted to the same extent as an English person who is well known in England. But if there is any question about it, you must have somebody in England responsible.

12754. (*Sir Mackenzie Chalmers.*) The difficulty is that they may be well known to scientific men in England, but not known to the public?—Yes; but I think the action of the Home Office should be regulated by the knowledge of scientific men. These public reputations are apt to be misleading in both directions. You will find, if you take the public estimate of men, that the best lecturer is considered to be the greatest man in research. My experience is by no means so. There are men with a magnificent power of exposition, who are thereby so well known to the public that they are supposed to be the leaders of science, whereas in truth they are merely bearers of good news from the front, and are in no sense the leading workers. May I pass to the second restriction recently suggested to the Home Office?

12755. (*Chairman.*) If you please?—The second is that a medical diploma should be required. In my opinion, specialisation has gone so far that the distinction between people who actually work practically at the curative sciences, and those who devote their lives to research in those sciences is becoming marked. A man who is actively employed in practice, as a first-rate man ought to be, has not usually the time for consecutive research; he has to get his time in fragments just when he can. On the other hand, there are many men who are so devoted to research that they give up medical practice as a method of earning their livelihood, and devote themselves entirely to research. The wide diffusion of wealth in this country facilitates this. England has always been noted in science for the numbers of its first-class amateurs. Cavendish was an amateur, and I could mention many other great

names of men who have had the wherewithal to devote themselves to research, and have made it their life's work without seeking any remuneration for their labour. What should guide the Home Office entirely is, whether or not the applicants for certificates or licenses are suitable for research. Whether or not they have taken out a medical diploma which gives them the nominal right to practice when they have no intention to do so, but mean to devote their whole time to research, is a matter which should be quite immaterial. I am quite satisfied that there are now, and there will be yet more such in the future, men in the very first rank of research work who do nothing in the way of the practice of medicine and who deliberately abstain from it because it would interfere with their scientific research by taking their time and their attention. Those people ought to be encouraged rather than discouraged. Therefore this proposed restriction would, in my opinion, be a retrograde step. So that I should strongly advise that neither of those two things should be adopted as a principle.

12756. Have you studied the Act with a view to suggesting amendments?—You see, I agree with a great deal of it, excepting that I think there are a certain class of men who should have these unrestricted powers of experiment, and that the practice of the Home Office with regard to non-painful experiments should not have regard to the nature of the experiment, but simply to the reliability of the person on whom is placed the responsibility of the anæsthesia. With these modifications I do not quarrel with the Act, because I do not think that the real worker if he is not really hampered in his research, chafes against these restrictions, which are, after all, only a recognition of what I might call the fundamental principle of his action. He is working that pain may be lessened. He is a person whom I have always found extremely sensitive to the cry of suffering, and he has no wish to protest against this Act, which does homage to that principle provided that it does not hamper him. I have not specially considered the provisions of the Act, because I thought it had been dealt with so much by people who knew its working, and are so much more qualified to deal with it than I am; but I doubt whether my conclusions clash very much with the Act as it at present stands.

12757. (*Sir William Church.*) I should like to ask one question with regard to those to whom you would grant these first-class certificates. Of course, you consider that any person who is placed in the position of head of a laboratory connected with a University or a public institution approaching in importance to a University would necessarily be a person of sufficiently good repute?—May I put it another way? I should hope that a University would never choose a man for the position who did not deserve it.

12758. Then, besides persons in charge of laboratories, you would grant these what you call first-class certificates to such men of repute; and in their case I understood you to say they should not be necessarily restricted to working in licensed laboratories?—No; I should leave them perfectly free, subject to report.

12759. So that they might work either in their own rooms or wherever was most convenient for their work to be done?—Yes, certainly.

12760. Then, with regard to all others who hold licences, I presume that you look forward to their all working in licensed laboratories?—Certainly. Of course, I should trust that the best of those who commenced with a licence would pass in time to the higher degree; but, as long as they only had a licence, they would work in proper laboratories subject to inspection.

12761. So that, even as you propose, it would not be possible for a research student, whether holding a medical diploma or not, for him to perform experiments on living animals even in a licensed laboratory, excepting if he held a licence himself?—No; not painful experiments. He could not perform painful experiments.

12762. And, of course, all those who held what you call first-class licences would be enabled to perform the experiments which are now performed under Certificate B without having to get anything further than their licence?—Yes, certainly.

12763. (*Sir Mackenzie Chalmers.*) I should like to take first the two points that you have raised about the Home Office practice. I suppose you agree that, apart from the wording of the Act, the Home Secretary is bound to have regard to public opinion to some extent—that there is a real danger of the powers being lost if suddenly public excitement were got up against them?—He is bound to have regard, I should say, to the Act. I think that he has no need to regard public feeling beyond the extent to which it is expressed in the Act.

12764. You think that his sole duty is to administer the Act, without regard to whether he is imperilling the existence of the Act or not?—I think that the safest way to maintain the Act is to administer it in the way in which it is best for research. The real defence of research will come from the good that it has done; and I think it would be an unwise thing to administer the Act in a niggardly way, in the hope that it would lessen the possibility of a popular storm. I do not myself fear very much the popular storm. I know perfectly well the power of a certain small number of determined people to prejudice the minds of the public, and I appreciate that it is considerable; but the more that the public has experience of the good results of research, the safer it is in the hands of the public.

12765. Of course, as regards the foreigner himself, the man who is temporarily over here, he is to some extent free from the law. He performs certain experiments, and the results of those experiments are not published, probably, until he has returned; and then the Home Secretary may be blamed for allowing the law to be broken by a man over whom he had not effective control. You recognise that difficulty, do you not?—He ought to have effective control, and I think that this would be best obtained by requiring that the reports should be sent in from time to time, and that there should be some responsible person to see this is done.

12766. Would you go so far as this, that supposing a foreigner were authorised to experiment, say, at University College, you would make the head of the laboratory there surety for him?—Yes; I would make him see that the thing is done. And if the man is not performing his duty, it is the duty of the head of the laboratory to report to the Home Office that the experiments are being carried out without due observation of the conditions.

12767. But what practical power of enforcing it have we? Would you withdraw the licence of the head of the laboratory if there were any contravention of the conditions by a foreigner working in his laboratory?—Not unless he connived at it. But, in my opinion, the report of an experiment should be written out as nearly as possible at the time; and if he neglects to see that this is done it appears to me that he is responsible for the breach.

12768. Now, coming to medical diplomas, is there not this difficulty: that when once you get away from the medical diploma, you have no guarantee whatever as to a man. If he belongs to the medical profession, he has been trained up in a profession whose sole object is, as you say, to diminish pain. When once you get outside that, where are you to get your information from as to the qualifications, moral and scientific, of a person who is to have this licence?—Would you say that we had no knowledge of the qualifications of Frank Balfour, before he was killed, so unfortunately, years ago. You will remember that he started a biological school at Cambridge which was full of the greatest promise? Do you think that the addition of a medical diploma would have made Frank Balfour a more reliable man?

12769. Personally I do not. But then, you must take the case of a good many persons who are not known to the public, and you must remember that public opinion is nervous on the question?—I should require the most exceptional testimony in the case of a man who had not done scientific study at a university and under proper training; but that it should have taken the form of medical study seems to me unnecessary. You must understand that the scientific degrees, though they are often taken by medical men, and ought to be taken by them, are in themselves independent. They may not qualify for a diploma, but they connote an amount of knowledge which would quite warrant your recognising the bearers as fit men, if they were duly recommended by those who advise the Home Office. Of course, you will occasionally meet with a man who without any scientific study in a recognised university is a man of pre-eminent value. Michael Faraday had had, I think, no university training at all. But those cases are extraordinarily rare,

Sir J. F. Moulton.
24 July 1907.

and would only be dealt with when vouched for in a way which was quite unexceptionable. So that, generally, you would have the security of university recognition that the applicant was properly qualified.

12770. Do you think that the existing certifying authorities, which are mainly medical authorities, under the Act, would be able to deal with the case of the people you refer to without medical qualification?—I think so.

12771. Or ought the advising body to be enlarged?—Those who examine up at the Universities usually possess medical degrees, and a great many of them possess also science degrees. I do not know whether Sir Michael Foster had a medical degree.

12772. (*Dr. Gaskell.*) Yes, he had, and practised?—I did not know that. But you can easily imagine that there may be some who have not.

12773. (*Dr. Wilson.*) Pasteur had not; he was a chemist?—No, Pasteur had not; that is a good example.

12774. And Metchnikoff was a chemist?—Yes.

12775. (*Sir Mackenzie Chalmers.*) Then I should like to ask your opinion upon this. It has been suggested to us by Mr. Coleridge, whose evidence, perhaps, you have not seen?—I have not.

12776. It has been suggested that a certificate of humaneness should be required before a licence was given. What is your opinion on that? He suggested, I think, that a certificate should be given by one Justice of the Peace and one minister of religion. Perhaps you would rather not express an opinion?—It is not enough to say that it is unnecessary. It would be an absolute insult to the people whom you would be consulting. The suggestion that the heads of the medical profession are not judges of humanity, of humaneness, I ought to say, is a piece of the most intolerable insolence. It is shocking when you consider the way in which, as a rule, medical men disregard their own comfort, and put themselves to any amount of trouble and discomfort for the purpose of helping people who are sick, very often when it does not bring to them the slightest *kudos* or the slightest pecuniary return. To suggest that such people do not know what humaneness is and are not moved by suffering is intolerable.

12777. I think the suggestion rather was from the evidence that we have had, that the present certifying authorities regard only scientific ends and qualifications, and do not consider as within their province the question of humanity?—So far as Englishmen are concerned (of whom I can alone speak from personal experience) the question as to whether they are likely to use power properly from the point of view of regard for suffering is from my knowledge of the people who are likely to take out licences practically settled before the application is made. But the certifying authorities have to advise that licences should be granted to the applicants, and if they think that *par exception* they are people who have not got any care for suffering, and will make a recklessly painful use of their powers, they are bound to say that they are not fit persons to receive licences.

12778. Do you think that ought to be expressed in the Act or the rules in any way?—I should say "fit and proper."

12779. You think that would cover it?—I think that would cover it.

12780. Now, coming to the ethical side of the question; may I rightly sum up your statement in this way—I want to know if I have understood it—that all pain is an evil, perhaps the supreme evil?—Yes.

12781. And that we are justified in the present infliction of a lesser evil when there is a reasonable prospect in the future of avoiding a very much greater evil?—Yes, quite so.

12782. That would be the test and the touchstone which we should apply to all animal experiments?—Yes, that is the touchstone. And in applying that touchstone we must conscientiously use the whole of the teaching that the history of science and the history of medicine have given us. The particulars I have given were in order to show that where there is serious research there is an overwhelming probability that the answer will be in the affirmative.

12783. Of course, as you know, by other ethical witnesses, we have had other tests suggested. For instance, one of the witnesses suggested to us that the test would be the conscience of a progressive people. I must say it did not convey very much information to my mind?—It conveys none to my mind. I feel satisfied that that is an extremely bad definition. "Conscience" is too often used where the true expression should be "emotion." Emotion may be a good motive power, but it is a bad guide, and, in my opinion, there is a very great deal of force in the phrase which somebody has used: "If you want to do good in a particular way, and want to know how you can do it effectively, give your heart a rest and your brains a chance." The only thing that can safely guide you is your reason. Your emotions may give you a motive just as I say that the motive which should dominate the whole of this quesion is the desire for the suppression of pain. When you have got that motive and desire to obey it, it is your reasoning power which ought to tell what you ought to do.

12784. What is pressed upon us continually is this: Admitted that pain is an evil, you have no right to inflict a definite voluntary amount of pain when the future saving of pain is absolutely problematical, what do you say to that argument?—It is simply because the people have not studied the question that they talk about its being absolutely problematical. What you have to do in life is to act on probabilities. It is quite impossible to prophesy exactly what will happen in the future, but when you see from the teaching which the past has given us that there is an overwhelming probability in favour of a thing happening you are bound to act upon that probability. Would a person refuse to take a medicine because it had not always cured people? It would be a doctor's duty to give it if there was a probability that it would do so.

12785. Then passing from what I call first principles to the secondary principles, if I have understood your evidence, you say that at any rate we have no right to prevent experiment for the purpose of increasing knowledge and controlling pain and disease while we allow the infliction of death and pain in sport for the purpose of providing food for mankind and for a mere commercial purpose, such as spaying sows and castrating horses?—Yes, and in infinitely more cases than those—cases in which, as I have said, you inflict pain for the purpose of preventing pecuniary loss. If you have a valuable dog you see it through the distemper. If it is not valuable you kill it to begin with. Yet you might be perfectly willing to sell that dog in any case. That is simply permitting suffering for the purpose of avoiding pecuniary loss. Otherwise, I really do not understand why people consider it right to kill beetles. Beetles will only destroy a certain amount of their food, and yet they extirpate them, just as they extirpate mice and they extirpate rats, and consider that they are justified in doing so, because they say that such animals do harm. That harm is really pecuniary harm.

12786. Perhaps the fairest way of putting some of these ethical points that have been put before us is to call your attention to a little publication I have just received from Mr. John Page Hopps, who has given evidence here. May I ask you to look at the second paragraph on page 3, beginning with the word "But." May I divide it into paragraphs and ask you whether you have any comments to make upon it. May I read the first words that I want to ask you about: "But when all is said on the score of results, and the 'artist in vivisection has done his best to convince us that he is the apostle of mercy, many grave considerations 'give us pause.' For instance, what law of God or Natures justifies this treatment of our poor relations? Who gave to this amazing enthusiast the right to say off-hand that he was at liberty to exploit 'the lower animals' for experiments?"—May I point out what it is that gives the whole force of that to the people he is talking to? It is the use of the word "experiments." They do not know what it means; they do not know its importance. Supposing I was to put, instead of "experiments" "saving life or stopping suffering," the whole appeal would fall to the ground. "Experiment" to an uneducated person does not connote what it does to persons who are acquainted with the nature and results of research. If you read it in that way: "Who gave to this amazing enthusiast the right to say off-hand that he was at liberty to exploit 'the lower animals' for saving human life?" the answer would be "Why not?"

12787. As regards that expression of his, "What law of God or Nature justifies this treatment of our poor relations?" what is your comment?—It is all based on this want of appreciation of the meaning and effect of scientific research. Supposing I was to put it, for instance, "What law of God or Nature justifies our killing things, or permitting them to suffer, in order to save us from pecuniary loss?" Yet we do this, and must do it, every day. A beetle is a poor relation, or a mouse is a poor relation, just in the same way as a guinea-pig is; and yet we treat our poor relations in the shape of mice and beetles with phosphorus, and let them die in pain, because we say we must keep them down.

12788. If his argument was right, as a logical conclusion we should have no right to keep a cat who destroys mice by a cruel and lingering death?—Certainly not. We should first kill all the birds of prey, and then kill the birds they prey on because they prey on insects; and then we should kill the greater part of those insects because they live, many of them, on still smaller things. You get back to the state of the Hindoo. Nobody ever dreams of doing that. It is only when it is applied to scientific research, the advantage of which they do not know, that these qualms come in.

12789. They do not believe in scientific research and its results. They honestly do not believe in it?—They do not believe in it; but that is entirely due to their not having studied and mastered the subject, otherwise language such as that would not have any effect.

12790. And Nature herself nearly always provides a cruel and lingering death for every wild animal?—Yes, it is terrible. I think it is Seton Thompson who says: "The end of every wild animal's life is a tragedy." And it is perfectly true.

12791. Now may I take you to the next sentence: "For laboratory purposes, his spectacles would not be safe in the streets; and if he put his proposal into effect, and got his babies on the dissecting table, the very costermongers would raid his laboratory, and even medical students might help them. Why? The cutting-up of one baby might save the lives of thousands of other babies; and the torture of one for an hour might save thousands from suffering for years. Why object?"—I object because you ought to get that knowledge in other ways. Everybody who has studied the subject realises that the knowledge can be obtained in other ways. The analogy between living creatures is so marvellously close that you can, without any experiments on mankind (excepting that you ultimately apply to them the methods which you have worked out scientifically), acquire all the knowledge that is necessary.

12792. It has been suggested to us that if we encourage experiments on living animals, it *per se* will tend to encourage experiments on human beings. What do you say to that argument?—It is the alternative of it. I remember a discussion in society on the subject of these experiments, and a lady at last put this question to the anti-vivisector: "Would you prefer an experiment to be tried on a cat or a baby?" And the person replied, "I would have no experiment tried at all," not seeing that when you have not got knowledge, when you are working blindly, all you do is one long series of experiments on mankind. You are just as really trying experiments; you are not trying experiments under such circumstances that they enlighten you, and the consequence is that the result of what you do is to add very little to our knowledge.

12793. You mean that as long as you are treating disease empirically in mankind, you are experimenting?—Purely experimenting. You are either just sticking to ignorance, or, if you are trying anything new, you are experimenting on mankind.

12794. Pressing Mr. Hopps' argument to its logical conclusion, it would come to this, I suppose: If experiments on animals lead to experiments on babies, the eating of animals for food would lead to eating human beings for food?—You are honouring his argument by attempting to follow it out. That is what it would naturally lead to. But, in the case of experiments, it is because we will not try the experiments on babies that we do them on animals.

12795. Would you kindly look at the last paragraph on page 35, and the first paragraph on page 36. I think you have really dealt with that question. Mr. Page Hopps says, talking of voluntarily incurred experiments: "There is a splendid opportunity here for the suicide. Instead of a coward in retreat, let him be a hero as an offering. 'The world,' he says, 'is full of misery—sordid, diseased, and despairing. I will get out of it.' He is full of pity for mankind, and is disgusted at its lot; so he decides to give it no help, but to go. What a lame and impotent conclusion! What an opportunity for heroism lost!" Does that strike you as somewhat unpractical?—I have dealt with that. It is not only impossible, but to my mind it is immoral in the highest degree, and it shows an absolutely crass ignorance of the nature of scientific research to think that by a few suicides you could replace the experiments on animals which, in a complicated matter like this, must be numerous, but need rarely be painful, and which, if they are painful, can, in the great majority of cases, be stopped by inflicting death.

12796. I suppose another difficulty would be that you would not get any scientific man to experiment on the would-be suicide?—If he did, he would probably be saved the trouble of suicide himself.

12797. Then Mr. Page Hopps, at page 36, makes another suggestion as regards minor experiments, as he calls them: "Or might it not be possible to connect some minor forms of vivisection with crime? Here is a criminal who has earned his fourteen years of penal servitude. Let him commute it for six months in the hands of a reliable vivisectionist, within limits. And so throughout the whole scale of penalties"?—I think that is loathsome levity, that is all I can say.

12798. Then, leaving that and coming to what you have said yourself, you thought that a man is not justified in experimenting on himself when there is any prospect of real danger?—Yes, I think so, unless he is obliged to do it—and I think he rarely is.

12799. Take a well-known instance. Haffkin invented a prophylactic serum, or injection rather, for plague, as you know?—Yes.

12800. The first person he tried it on was himself. Was he justified or not?—Certainly he was justified if he had scientifically worked it out till he had a well-grounded right to expect that it would not lead to evil consequences. At that stage a man may justifiably, and to the great benefit of the human race, experiment upon himself.

12801. Either on himself or any other person who thoroughly knows what he is doing and consents?—Yes.

12802. (*Chairman.*) It is very like Columbus taking out his ship to discover America?—Yes, except that Columbus ought to have made a few more observations before he did it.

12803. He had good reason for believing that there was land out there?—No doubt.

12804. (*Sir Mackenzie Chalmers.*) Would you justify the course of experiments of Dr. Leonard Hill and his assistant experimenting on themselves in the way of testing how many atmospheres they could subject themselves to?—Yes. That is a most interesting instance. He had worked at the subject until he felt clear that he had got, if I might use the phrase, the rule of danger, and having worked it out he had the confidence to submit himself to it, and in that way he enormously assisted the acceptance of his methods. I think he was right. But he would have been perfectly wrong to go trying one method after another upon himself before he had worked his method out to that high degree of scientific probability.

12805. I think the only difficulty that I feel is this, where do you draw the distinction between the man who, for a scientific purpose, submits himself to a dangerous experiment, and a doctor who goes into a hospital reeking with typhus at the imminent risk of his life, to carry on the ordinary work of his profession?—I said that I made an exception when it was necessary to save human life. You see, if a doctor knows that if he does not do that many lives in that hospital will certainly be lost, I think then that he is perfectly right to say, Well, I will risk my life in order to save those lives. But in the other case, I think that he is a bad scientific man if he does not find a way of working it out, without exposing his life, up to a point when he is justified in doing so. That is my feeling. In giving this evidence, I have in my mind all the time what science is. Science is not the bungling, haphazard sort of thing that the world outside believes it to be. It is organised common sense, enlightened by appeals to actual fact, which are framed for the express purpose of giving

Sir J. F. Moulton.

24 July 1907.

you the information which is necessary for your common sense to act upon. And when you realise this you feel that the man who is content to follow scientific methods is not driven to these heroic steps, he can, with the minimum of suffering to animals and without endangering human life, work out the problems which are before him. If he is impatient he would like, perhaps, to experiment upon himself or on men, but if he is patient he need not do so. And I want the scientific man to be patient in that way.

12806. There is only one other question that I want to ask you. You urge the importance of painless experiments before students?—Yes.

12807. On the old principle *Segnius irritant animos demissa per aures*?—Yes.

12808. But what we have been told is that the performance of these experiments tends to demoralise students, tends to create a morbid curiosity as to pain in their minds. What is your opinion as to that?—My opinion is that that fear is entirely bred in the minds of the people who express it. I do not believe there is the slightest justification for it. We compel students to be present at operations on living men and living women because we feel that we must do so, and no one would listen to the suggestion that they ought not to be present there. How in the world can it have a bad effect when they see operations on animals if it does not when they see them performed on man? I do not believe that there is the slightest justification for the fear, and, as a rule, I do not like or attach any importance to suspicions as to impurity in other people without adequate evidence.

12809. (*Mr. Tomkinson.*) All your evidence, I think, is pretty well based upon the assumption that practically perfect anæsthesia can be and is maintained in these physiological experiments?—Yes.

12810. And you have no qualms about it as to the possibility of perfect and continued anæsthesia in operations?—I have no doubt whatever about it. Some one expressed it to you in a way which I think exactly represents the truth, viz., that consciousness is the first thing to go and the last thing to come back.

12811. (*Dr. Gaskell.*) Consciousness of pain?—Yes, consciousness of pain, I mean, is the first thing to go and the last thing to come back. We have the experience of people who have had the most serious and long-continued operations performed upon them, and have come back to consciousness, and their universal testimony is to absolute unconsciousness of pain.

12812. (*Mr. Tomkinson.*) Then that being the case, and anæsthetics being an established fact, there is no reason for me to ask you how far you would press your theory of the justifiableness of inflicting pain, even intense pain, upon individual creatures in order to prevent a much larger amount of suffering spread over a vast number of individuals; in other words, the infliction of vicarious sacrifices?—You ought only to do that where it is necessary for you to get the knowledge which will enable you to prevent pain in future, just in the same way as if in my simile of the plague-stricken ship. I think the man ought to take the most painless method that is applicable to kill those rats, but he must kill them even though it should be painful.

12813. But then that is to avoid and prevent a gigantic danger?—Yes.

12814. That would hardly be on all fours with a very painful experiment—an awfully painful experiment, say—upon an animal for a possibility of discovery?—That is just the point. There have been many painful experiments in discovering the true nature of disease which, as I say, makes us think so differently about all these microbic diseases that we cannot put ourselves back into the ignorance of 50 years ago; but they have been for the purpose of ascertaining the nature of these diseases in order that we might fight them. The number of very painful experiments is very few—extremely few. The greater number of the experiments have been of inoculations, and as soon as the disease has developed itself the animal is killed, because what the experimenters have wanted to find out was aye or no, would the disease be taken under such circumstances. The number of cases in which you have to allow really painful experiments is confined to these—that is, the cases where you are examining the distant effects of certain lesions of the nerves of interference with the digestive organs in order that when you see symptoms which are so produced you may know where the evil is. They are never, I think, performed casually; the very painful ones would almost always, I should think, in the history of English research in physiology be performed for some very definite object, in order to give us this very essential knowledge.

12815. And as a matter of fact, with regard to the destruction of dangerous or destructive animals, the common way of trapping them is about as cruel as can be adopted?—Quite so.

12816. And yet it is recognised?—Quite so.

12817. You probably would agree with me that some more stringent law in the direction of prevention of cruelty to animals would be very desirable in those regards?—Yes, I agree. That is just what I feel. I feel that this infliction of pain for the purpose of knowledge is the last thing you ought to touch. I should be very strongly in favour of legislation for lessening pain, if such a thing were possible; but I am happy to say that the need grows less. I think that there is a growing of increased sensitiveness towards suffering which would help legislation of the kind that you speak of, and which is even rendering such legislation unnecessary. I see it everywhere.

12818. Another instance, that entirely misleading statement of baking rabbits prompts the question of the boiling of lobsters?—Yes. There may be much that one might advantageously inquire into there.

ROYAL COMMISSION ON VIVISECTION.

FOURTH REPORT

OF

THE COMMISSIONERS.

Presented to both Houses of Parliament by Command of His Majesty.

LONDON:
PRINTED FOR HIS MAJESTY'S STATIONERY OFFICE,
BY WYMAN AND SONS, LIMITED, 109, FETTER LANE, E.C.

And to be purchased, either directly or through any Bookseller, from
WYMAN AND SONS, LIMITED, 109, FETTER LANE, FLEET STREET, E.C.; and
32, ABINGDON STREET, WESTMINSTER, S.W.; or
OLIVER AND BOYD, TWEEDDALE COURT, EDINBURGH; or
E. PONSONBY, 116, GRAFTON STREET, DUBLIN.

[Cd. 3954.] *Price* $\frac{1}{2}d.$

ROYAL COMMISSION.

WHITEHALL, 17TH SEPTEMBER 1906.

The KING has been pleased to issue a Commission under His Majesty's Royal Sign Manual to the following effect :—

EDWARD, *R. & I.*

EDWARD THE SEVENTH, by the Grace of God, of the United Kingdom of Great Britain and Ireland and of the British Dominions beyond the Seas King, Defender of the Faith, to

Our right trusty and well-beloved Cousin and Councillor WILLIAM COURT, VISCOUNT SELBY ;

Our right trusty and well-beloved Councillor AMELIUS MARK LOCKWOOD, Commander of Our Royal Victorian Order, Honorary Colonel of the 4th Battalion of the Essex Regiment ; and

Our trusty and well-beloved :—

SIR WILLIAM SELBY CHURCH, Baronet, Knight Commander of Our Most Honourable Order of the Bath, Doctor of Medicine ;

SIR WILLIAM JOB COLLINS, Knight, Doctor of Medicine ;

SIR JOHN MCFADYEAN, Knight ;

MACKENZIE DALZELL CHALMERS, Esquire, Companion of Our Most Honourable Order of the Bath, Companion of Our Most Exalted Order of the Star of India, one of the Under-Secretaries of State to Our Principal Secretary of State for the Home Department ;

ABEL JOHN RAM, Esquire, one of Our Counsel learned in the Law ;

WALTER HOLBROOK GASKELL, Esquire, Doctor of Medicine ;

JAMES TOMKINSON, Esquire ; and

GEORGE WILSON, Esquire, Doctor of Medicine ;

GREETING !

Whereas We have deemed it expedient that a Commission should forthwith issue to inquire into and report upon the practice of subjecting live animals to experiments, whether by vivisection or otherwise ; and also to inquire into the law relating to that practice, and its administration ; and to report whether any, and if so what, changes are desirable ;

Now know ye that We, reposing great trust and confidence in your knowledge and abililty, have authorized and appointed, and do by these Presents authorize and appoint you, the said William Court, Viscount Selby (Chairman) ; Amelius Mark Lockwood ; Sir William Selby Church ; Sir William Job Collins ; Sir John McFadyean ; Mackenzie Dalzell Chalmers ; Abel John Ram ; Walter Holbrook Gaskell ; James Tomkinson ; and George Wilson to be Our Commissioners for the purposes of the said inquiry

351. 2500—Wt. T.L 306.—3/08. Wy & S.

And for the better effecting the purposes of this Our Commission, We do by these Presents give and grant unto you, or any five or more of you, full power to call before you such persons as you shall judge likely to afford you any information upon the subject of this Our Commission ; and also to call for, have access to and examine all such books, documents, registers and records as may afford you the fullest information on the subject, and to inquire of and concerning the premises by all other lawful ways and means whatsoever.

And We do by these Presents authorize and empower you, or any five or more of you, to visit and personally inspect such places as you may deem it expedient so to inspect for the more effectual carrying out of the purposes aforesaid.

And We do by these Presents will and ordain that this, Our Commission shall continue in full force and virtue, and that you, Our said Commissioners, or any five or more of you, may from time to time proceed in the execution thereof, and of every matter and thing therein contained, although the same be not continued from time to time by adjournment.

And We do further ordain that you, or any five or more of you, have liberty to report your proceedings under this Our Commission from time to time, if you shall judge it expedient so to do.

And Our further will and pleasure is that you do, with as little delay as possible, report to Us under your hands and seals, or under the hands and seals of any five or more of you, your opinion upon the matters herein submitted for your consideration.

And for the purpose of aiding you in your inquiries We hereby appoint Our trusty and well-beloved Charles Clive Bigham, Esquire, Companion of Our Most Distinguished Order of Saint Michael and Saint George, Captain in Our Army, to be Secretary to this Our Commission.

Given at Our Court at *St. James's*, the 17th day of September 1906, in the sixth year of Our Reign.

By His Majesty's Command.

H. J. GLADSTONE.

Note.—His Majesty was subsequently pleased to create Mr. Chalmers a Knight Commander of the Most Honourable Order of the Bath.

ROYAL COMMISSION ON VIVISECTION.

FOURTH REPORT.

TO THE KING'S MOST EXCELLENT MAJESTY.

MAY IT PLEASE YOUR MAJESTY,

Availing ourselves of Your Majesty's permission to report our proceedings from time to time, we beg to submit to Your Majesty, as an Appendix to this our Fourth Report, Minutes of the Evidence taken during the months of October, November and December, 1907, as we think the present publication of these documents is desirable.

ALL WHICH WE HUMBLY SUBMIT FOR YOUR MAJESTY'S MOST GRACIOUS CONSIDERATION.

SELBY (*Chairman*).

M. LOCKWOOD.

W. S. CHURCH.

W. J COLLINS.

J. McFADYEAN.

M. D. CHALMERS.

A. J. RAM.

WALTER H. GASKELL.

JAMES TOMKINSON.

GEORGE WILSON.

CLIVE BIGHAM (*Secretary*).

December, 1907.

ROYAL COMMISSION ON VIVISECTION.

APPENDIX

TO

FOURTH REPORT

OF

THE COMMISSIONERS.

MINUTES OF EVIDENCE,

October to December, 1907.

Presented to both Houses of Parliament by Command of His Majesty.

LONDON:
PRINTED FOR HIS MAJESTY'S STATIONERY OFFICE,
By WYMAN and SONS, Limited, 109, Fetter Lane, E.C.

And to be purchased, either directly or through any Bookseller, from

ROYAL COMMISSION ON VIVISECTION.

LIST OF WITNESSES.

In the order in which they appeared before the Royal Commission.

Date.	Name of Witness.	Profession, Occupation or Residences.	Representing.	No. of First Question.	Page.
1907. 29th Day - Oct. 23rd.	Mr. JOHN GLAISTER, M.D.	Professor of Forensic Medicine and Public Health, Glasgow University.	Faculty of Physicians and Surgeons of Glasgow.	1,2819	1
30th Day - Oct. 29th.	Mr. S. F. SMITH, M.R.C.S.	Surgeon to the Anti-Vivisection Hospital.	- - - - - -	13,030	10
31st Day - Oct. 30th.	Mr. F. GOTCH, M.A., D.Sc., F.R.S., M.R.C.S.	Professor of Physiology, University of Oxford.	Faculties of Medicine and Science, University of Oxford.	13,539	31
	Mr. M. S. PEMBREY, M.D.	Lecturer on Physiology at Guy's Hospital.	- - - - - -	13,968	49
32nd Day - Nov. 5th.	Colonel D. BRUCE, C.B., F.R.S., R.A.M.C.	- - - - - - -	Committee of Medical and Scientific Societies.	14,184	58
33rd Day - Nov. 6th.	Mr. G. G. BANTOCK, M.D., F.R.S. (ED.)	Consulting Surgeon to the Samaritan Free Hospital for Women.	Parliamentary Association for the Abolition of Vivisection.	14,530	76
34th Day - Nov. 12th.	Mr. J. N. LANGLEY, M.A., D.Sc., F.R.S.	Professor of Physiology, University of Cambridge.	University of Cambridge.	15,099	98
	Mr. G. SIMS WOODHEAD, M.A., M.D.	Professor of Pathology University of Cambridge.	University of Cambridge.	15,426	113
35th Day - Nov. 13th.	*Sir VICTOR HORSLEY, F.R.S., F.R.C.S. (App. A., I. and II.)	- - - - - - -	British Medical Association.	15,583	118
36th Day - Nov. 19th.	- - (recalled)	- - - - - - -	- - - - - -	15,966	138
	Mr. F. HOBDAY, F.R.C.V.S., F.R.S.E.	10, Silver Street, Kensington.	- - - - - -	16,284	150
37th Day - Nov. 20th.	Mr. W. OSLER, M.D., F.R.S., F.R.C.P.	Regius Professor of Medicine, University of Oxford.	Faculties of Medicine and Science, University of Oxford.	16,524	157
	Lieut.-Col. E. LAWRIE, M.B., I.M.S. (Retd.)	- - - - - - -	- - - - - -	16,793	167
38th Day - Nov. 26th.	Mr. JOHN HUGHES -	Secretary of the National Canine Defence League.	National Canine Defence League.	17,109	175
	Mr. J. ROSE BRADFORD, M.D., D.Sc., F.R.C.P. F.R.S.	Professor of Medicine, University College, London.	Committee of Medical and Scientific Societies.	17,621	189
39th Day - Nov. 27th.	Mr. H. HEAD, M.A., M.D., F.R.S., F.R.C.P.	Physician to the London Hospital.	Committee of Medical and Scientific Societies.	17,801	195
	Mr. A. D. WALLER, M.D., LL.D, F.R.S.	Lecturer at the University of London.	London University -	17,996	203

* *An asterisk is placed against the names of those witnesses by whom statistical tables, etc., were put in, which have been reprinted as Appendices, and the number of the Appendix put in is indicated in each case in brackets after the witness' name.*

Date.	Name of Witness.	Profession, Occupation, or Residences.	Representing.	No. of First Question.	Page.

MINUTES OF EVIDENCE

TAKEN BEFORE THE

ROYAL COMMISSION ON VIVISECTION.

Wednesday, 23rd October 1907.

TWENTY-NINTH DAY.

PRESENT:

The Right Hon. The Viscount SELBY (*Chairman*).

Sir W. S. CHURCH, Bart., K.C.B., M.D.
Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir J. MCFADYEAN, M.B.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. A. J. RAM, K.C.
Mr. W. H. GASKELL, M.D., F.R.S.
Mr. J. TOMKINSON, M.P.
Mr. G. WILSON, LL.D., M.D.
Captain C. BIGHAM, C.M.G. (*Secretary*).

Mr. JOHN GLAISTER, M.D., called in, and Examined.

12819. (*Chairman.*) You are a Professor of Glasgow University?—I am—Professor of Forensic Medicine and Public Health.

12820. And you have been desired by the Faculty of Physicians and Surgeons of Glasgow to give evidence here?—I have.

12821. Is that one of the licensing bodies qualified to give diplomas in medicine and surgery?—Yes, and also diplomas in public health.

12822. And you are a Doctor of Medicine yourself, I believe?—I am, of the University of Glasgow.

12823. And you are a Fellow of the Faculty of Physicians and Surgeons of Glasgow, and a Licentiate also of the Royal College of Physicians and Surgeons of Edinburgh, and you have other qualifications?—That is so.

12824. Have you yourself ever taken out a licence under the Act?—No, I have not had facilities until now. I have a place which has now been registered in my new buildings, in my new department. I have not done so before, because I had no accommodation for animals, as a matter of fact. Now I have a building which is registered under the Act for the purpose.

12825. (*Sir William Collins.*) Do you hold a licence?—Not yet; I have not applied for one.

12826. (*Chairman.*) Do you propose to do so?—Yes, immediately.

12827. The subject is one that you have studied?—Yes, for 25 years I have been a teacher on the subject.

12828. But you have never had a licence yourself?—I have never held a licence up till now.

12829. At the same time you are familiar with the Act of Parliament?—I know it, and I think I know all about the certificates.

12830. And you are familiar with experiments on animals?—Yes, very familiar. I may add that on several occasions I have had to sign the certificates of others. Being one of the statutory certifiers under the Act I have had for some years to act as a signator of the certificates of others.

12831. Have you found any difficulty in carrying out your duties as a certifier under the Act?—No, I have never had any difficulty on the question as to the need for experiments upon animals. Before signing a certificate I have always satisfied myself of two things. First, that the applicant was a capable person to perform the experiment; and, secondly, that the experiments, in my mind, ought to be performed.

12832. And you have always been able to deal satisfactorily with those points?—Yes.

12833. In that respect, as regards certifying, is there any amendment that you would like to suggest in the Act?—The only suggestion that I would make is this. So far as I am able to see, the certificate "A," which is usually confined to inoculation and feeding experiments, is not large enough for such work as my own, for example. As Medico Legal Examiner to the Crown in Glasgow and the West of Scotland, charged with the duty of examining *post-mortem* the bodies of those who die sudden and violent or suspicious deaths, I am required to report to the Crown as to the cause of the death. In some cases the death has been due to poisoning; it may be from food or ordinary poisons, or more occult poisons, and, if one in Certificate "A" laid oneself down to ask for a certain number of experiments, on account of the uncertainty of the amount of work to be done in the year, one might have some difficulty in having the number of animals named in the certificate not exceeded; that is to say, I might require more animals in one year than in another, and if I put down a certain number, or, if the number were laid down for me by the Home Office, I might not be able to conduct the work. I would like to say further that I understand there is a certificate, which has not, I think, been mentioned in the evidence, so far as I have read the three volumes, called "A 2," which has been issued by the Home Office to a small number of investigators. I have only seen it scheduled in the last few days. The terms of that certificate would be quite satisfactory to me, inasmuch as the number of experiments is not named, the time of carrying out the work is not laid down, and the range of work would cover all that I personally would require.

12834. (*Mr. Ram.*) Have you got a copy of it?—I have only got a copy in writing.

12835. (*Sir John McFadyean.*) May I ask is it quite the rule that in Certificate A the number of experiments is limited?—I cannot say. I have only seen one of these certificates, and the only certificate that I saw did not bear any number of experiments.

(*Sir Mackenzie Chalmers.*) Have you ever applied for a certificate with regard to your duties and been refused?—As I have already explained to his Lordship, I have never applied for a licence or certificate at all, because up till now I have not had facilities. I have now, and my place is registered, and I am just waiting to get a comprehensive enough certificate to make an application.

Mr. John Glaister, M.D. 23 Oct. 1907.

12837. (*Chairman.*) Your attention has been particularly directed, I presume, from what you have said of your duties, to the question of discovering poisons in the human body?—To the discovery of poisons in the human body and making investigations there anent.

12838. And as to the symptoms which those poisons develop?—Yes; and I may add further that there is a range of causes of poisoning due to food, of which I have had several cases in the last few years, which are more difficult to deal with than many cases of mere mineral poisons. My assistant, for example, is Medical Officer of Health of a burgh, and he works with me in any epidemic disturbance that there is. There was an epidemic of milk poisoning in which 600 people were involved, and I should like, of course, to be able to include in my work such investigations as that kind of work would demand—food poisoning.

12839. You mean in the new registered building which has been provided?—Yes.

12840. That is specially what you would like to experiment upon?—Precisely.

12841. Other things besides milk, of course?—Yes, any kind of food.

12842. What kind of poisons are developed there. How do you speak of those?—The cases which come under one's investigation are, for example, in the case of shell fish, the case of the typhoid fever bacillus, the bacillus coli communis, which is a type of bacillus, Gaertner's bacillus which is called the bacillus enteritidis, and a third group, the sausage bacillus, the bacillus botulinus. These form groups of meat poisoning micro-organisms, some of which form toxins, that is to say, the products of their growth, which of themselves are poisonous, apart from the existence of the organism itself. I had a case, for example, within the last three months in which the criminal authority of a neighbouring county sent me the internal organs of a girl, one of a series who were made ill and had died after eating sausages.

12843. (*Sir William Collins.*) Could you not deal with that case then?—I could only deal with that case chemically, and I got an experiment made, which I adopted, by a colleague whose licence covered such an investigation.

12844. (*Chairman.*) Do you consider that it is necessary to make experiments upon animals for the purpose of making these investigations about poisons?—I have no doubt about it. I think it is essential. I have mentioned in my précis the very well-known Dr. Lamson poisoning case, in which aconitin was the active poison, of which the poisonous doses are an infinitesimal part of a grain, and in which case Sir Thomas Stevenson discovered the poison along with Dr. Dupré, partially by experiments upon himself and upon mice.

12845. (*Sir Mackenzie Chalmers.*) Everything that was required was done in that case, was it not?—Absolutely. I am only pointing out that you require animals to test whether you are dealing with aconitin or not. I say without this physiological test you cannot detect your poison.

12846. (*Chairman.*) You cannot detect it by a chemical process?—No, you cannot prove it by chemical process.

12847. (*Mr. Tomkinson.*) The effect must be watched upon living animals?—Precisely.

12848. (*Sir Mackenzie Chalmers.*) Dr. Stevenson, in fact, experimented upon himself as well, did he not?—I have just said so. No chemical test would reveal that poison, but a physiological test would.

12849. (*Sir John McFadyean.*) Was that before the passing of the Act?—No, it was in 1882, I think.

12850. (*Sir William Collins.*) What animals did he use?—Mice.

12851. (*Chairman.*) That investigation of food, I suppose, is of growing importance, there being so much preserved food—tinned food?—I think it is absolutely essential—that we must have animals to experiment upon in such cases as those. The subject is yet in its infancy; it has to be opened up yet.

12852. Are there any other aspects of public health which make experiments of this kind necessary?—If you take a disease, such as cerebro-spinal meningitis, we have been having a large outbreak of it in Scotland during the past two years. I have the official figures here, and during this present year, 1907, from February to September in Scotland there have been 1,611 cases reported to the Local Government Board. Of these 1,028 occurred in the county of Lanark, in which Glasgow is situated. During 1906, up to March of this year, in Glasgow there were 312 cases and 230 deaths, a death rate of about 70 per cent., 73.7, to be quite accurate, and in the present year, between the 29th of March and the 11th of May the number of cases was 229. The question at issue with regard to that disease is how is the disease propagated. We have great difficulty in knowing how the disease is propagated now. An investigation has been started with regard to an examination of the air passages of apparently healthy persons acting as passive carriers; that is to say people who have been in contact with a case of the disease have been found to carry passively in their upper air passages this organism, and it has been found in these. That subject must be elaborated, and the nature of the organism itself has to be discovered. This disease simulates certain cases of food poisonings. In 1902 I was asked by the Corporation of Paisley, an adjoining burgh to Glasgow, to make an investigation regarding the causes of illness of several persons; I forget whether six or nine, three of whom had died, to make a *post mortem* examination on the body of one of the victims, and to report. I was able in that case to discover and isolate and photograph the organism of this disease. We do not know much about it yet, and one must make experiments upon animals in that direction.

12853. When you say an organism of this disease you mean a microbe?—A microbe. Of course we know the microbe, and we know how to grow it, but it is in its relation to its spread and other things that we want to make investigation.

12854. (*Sir Mackenzie Chalmers.*) Are animals susceptible to this disease?—That I cannot tell you. That is one of the things we want to find out—whether animals are the vehicle of contagion or not.

12855. (*Chairman.*) Have you experimented on animals?—No, I have not. I am eager to begin.

12856. Has it been done with regard to this disease?—Not so far as I know up till now. It has not been done in this country much so far as I can make out.

12857. (*Mr. Ram.*) It could be done to-day?—Yes, it could be done under the Act.

12858. (*Sir John McFadyean.*) When you say that it has not been done in this country have there not recently been some experiments carried out by Dr. Stuart McDonald in Edinburgh with regard to monkeys?—Yes.

12859. (*Mr. Tomkinson.*) Do you hold that this microbe must be either communicated by infection or caused by some specific food or other, and is never a natural growth?—I did not say that. All microbes, of course, must proceed from previous microbes, but the question of their communication from one person to another is the question in which difficulty is experienced just now—how was it spread? If we knew that we might devise preventive measures.

12860. But it does spread?—Yes, undoubtedly it does spread.

12861. By infection?—I think so.

12862. (*Chairman.*) Then at present all that you have to say about that is that you look forward to experiments upon animals to assist you in discovering how it spreads?—I think investigators will require to call in the help of animals to elucidate these points.

12863. You are not in a position to say that any experiments have been made which have thrown any light on the subject at present?—No, because the information which one of the Commissioners kindly referred to just now with regard to monkeys would not throw any light upon the possible spread, as of course we do not have monkeys in this country except as caged animals.

12864. Then as regards the wilful poisoning, the criminal poisoning of people, what is your experience?—I think I can safely say that there are a certain number of alkaloids which are so poisonous that I do not think any chemical means could possibly detect them, of which we know comparatively little now, and which must be investigated by the agency of animals.

12865. You do not think that any improvement in the knowledge of chemistry would do it?—I do not think so, for this reason, that it is a more difficult task than even looking for the proverbial needle in a haystack.

If the poisonous dose, for example, of a drug be half a grain (and that is an exaggerated case with regard to some of them), and that is taken into the body and causes the death of the individual, the most accurate chemical processes would not be able to isolate from the remains of that body anything like half a grain, and even if rescued, as in the case of aconitin, chemical tests would not enable one to say what it was; physiological tests might, and probably would.

12866. Have experiments increased your knowledge of those poisons that you speak of—aconitin and alkaloids?—They have materially, regarding their action, and it is because of their action upon animals having been ascertained by experiments that one is able by taking an alkaloid, of which we do not know the precise nature, and putting it into an animal, to get to know that the poison is aconitin. I may point out in that connection that there are other questions associated with poisoning of very great importance; for example, the best antidotal remedy for acute arsenical poisoning, assuming a person wilfully or accidentally poisoned by arsenic, was really brought into practical operation by experiments on animals. We had never known about this except theoretically until it was distinctly found to be valuable from researches upon animals. In the early thirties of last century in theory it was believed that the use of a certain preparation of iron would be beneficial. Between 1834 and 1840 certain experiments were made on the dog and on the horse, which showed that this hydrated ferric-oxide, freshly made, would be distinctly antidotal. In 1861 Dr. Watt published in the "Ohio Medical and Surgical Journal" for March of that year certain experiments which he performed on five dogs, in which he gave them poisonous doses of arsenic, and at varying intervals thereafter this freshly-prepared iron oxide, and showed the beneficial effect which resulted therefrom.

12867. He gave it as an antidote?—He gave it as an antidote, and his object was to show that this substance was an efficient antidote if used after the poisoning within a given period.

12868. You say that he found that it was a satisfactory antidote. Did the dogs recover?—I will just tell you the facts. He administered arsenic alone to five dogs in different doses from three grains upwards, and all of those dogs died from the effects of the poison within eight hours after the administration. To a second series of twelve dogs he administered varying doses of arsenic, all of them lethal doses, but afterwards administered to them the antidote, in some instances not until the poisonous symptoms had appeared, but all the animals recovered; and it is upon evidence of that kind that we now in all our books and all our teaching recommend this as an antidote to arsenic.

12869. And is it used for arsenical poisoning of human beings?—Yes, it is the antidote used to-day.

12870. Does it have the same effect as it had upon the dogs, of curing them?—Yes, there have been many cases recorded of recoveries from arsenic poisoning where it has been administered.

12871. Do you attribute that discovery entirely to those experiments?—Surely. Before that it could only be theory.

12872. What gave rise to the theory?—The theory is that if you take a solution of arsenious acid you can precipitate that as the insoluble salt of iron with an iron preparation. You can do that in a test tube—everybody knew that—but the question came to be how could it be practically applied to the human stomach? Could you utilise in any way the human stomach as you would use the test tube? And it was with the object of discovering that practically that these and many other experiments were carried through.

12873. Was this dose that was given as an antidote to human beings the same liquid that was put in to operate upon the arsenic in the tube?—The same preparation precisely, only in the human stomach the quantity of iron oxide must be considerably increased in order to get the same effect.

12874. Then this was a case in which from chemical tests you had discovered the probability of the remedy being effective?—Yes, through the physiological medium of application to individual animals.

12875. And it was to make sure of the results in the human stomach that you tested it on animals?—Yes, and in order to know how it could be made sure—by what doses.

12876. (*Sir Mackenzie Chalmers.*) What I understand is that this remedy was first tried in a test tube, then tried on a dog, and then, having answered those two tests, it was used successfully with human beings?—Yes; the experiments on dogs determined the amount of the antidote to be used to the poison—the method of use.

12877. (*Chairman.*) What I wanted to get, and what I think you have given me, is that the scientific fact that this was an antidote was discovered in the tube by chemistry?—Yes, exactly.

12878. But it was not safe or certain as a remedy to human beings until you had tested it upon animals? Surely not, because we cannot use the human stomach as a test tube—the two things are different.

12879. Are there any other special cases of valuable testing of poisons to which you wish to call attention?—I desire to draw attention to one more, and it is a rather interesting one. It is the case of a very fatally poisonous arsenical gas called arseniuretted hydrogen. A few years ago I had two cases of this occurring in a very curious way. A man engaged in chemical works in the manufacture of bleaching powder in a Welldon's retort suddenly became overpowered, and had to be taken out. He died within three days. The man who followed him also was overcome, but he recovered. The process of making bleaching powder by a Welldon's retort is this: Hydrochloric acid is mixed with a certain proportion of manganese dioxide; the manganese dioxide acts upon hydrochloride acid, liberates the chlorine gas, which saturates the lime and forms the bleaching powder. The retort is made to work continuously, night and day, for from two to three weeks. At the end of that time a workman has to proceed in from the top by means of a rope ladder after the retort has been steamed out with live steam to dig out and remove what is called by the workmen the mud, the débris, which lies at the bottom of the still. I was called in to consult with other doctors regarding this man before his death, and after seeing the man I went to the chemical works and got the details of the process just as I have described them. I came to the conclusion that the man died from this gas. The case required to be reported to the Home Office. It was reported, and the man having died, a *post-mortem* examination of his body was made, and Sir Thomas Stevenson, who chemically examined the remains, found arsenic therein. The interesting thing about that case is that this arsenical gas did not exist in the retort when the men went into it. As the implements for the removal of this mud they took an iron shovel and a zinc galvanised iron pail, and they themselves manufactured the gas which caused their death. They manufactured on a large scale what we know as the Marsh's test for arsenic, after Mr. Marsh, who invented the test in 1836. They generated the gas which killed them. Since these cases I have investigated the literature of the world, and I have found a large number; I have collected over 100 cases of deaths from this cause in a large variety of occupations, and perhaps your Lordships will be aware that in the State Ballooning Department of France several deaths have already occurred from this gas being present in the impure hydrogen by which the balloons are inflated. All the evidence that we have regarding the physiological effect of this gas is from experiments made on the Continent. I am not aware of a single experiment having been made in this country on that subject.

12880. What is the sort of experiment on an animal that you would suggest, if it had to be made?—The experiments on the Continent have been by subjecting dogs to varying percentage proportions of this gas mixed with air, and studying the symptoms that follow. My attention will be directed, not to the result of the gas, but to the prevention or cure of it when it happens. Nothing has been done in that way so far as I know. There have been various suggestions.

12881. You would have first to ascertain what in all probability would be the antidote, I suppose?—Yes, for this reason. This gas acts differently from arsenic itself; it breaks up the corpuscles in the blood; it acts directly upon the blood, and thus an antidote is more difficult to be arrived at.

12882. But when you have discovered the antidote you will have to test it upon animals?—Yes, we must use animals. I would not dare use anything else than an animal for this.

Mr. John Glaister, M.D.

23 Oct. 1907.

12883. Is there any other fact you would like to bring before us as regards poisoning and experiments upon animals?—May I just finish by adding in a group answer that our knowledge of antidotes with respect to a large variety of mineral and vegetable poisons has been derived from experiments upon animals of different kinds. I have a whole list here of those of which I have data, and to which I can give references.

12884. Perhaps you will furnish them to the Commission?—These are some of them: Mercuric chloride, examined by Sir Benjamin Brodie on rabbits and cats, and the reference is "Philosophical Transactions," Vol. CII., page 222 (1812). Tartar Emetic: Magendie (*Mémoire, sur l'émétique*), experimented on dogs with and without the gullet being tied. (Orfila-*Toxicologie Générale*, Vol. I., page 469.) Lead Poisoning: Orfila, Christison and others examined the effects by its action on animals. (Christison on Poisons, 4th Edition, 1845, p. 548 et seq.) Prussic Acid: Magendie experimented on dogs and birds (*Annales de Chimie*, Vol. VI., page 347; Christison on Cats, Op. cit., page 757.) Hemlock: Orfila on Animals. Christison in 1835 found it a deadly poison for dog, cat, rabbit, mouse, frog, fly and flea; and Geiger, for kitten, pigeon, swallow, glowworm and earthworm. Laburnum: (Ross on Dogs. Christison on Rabbits, op. cit.). Strychnia: Marshall Hall's test with frogs. (Wormley on Poisons, p. 584.) Digitalis and Digitalin, by Tardieu, on frogs in the Pommerais case (Author's Manual, page 493).

12885. You said, I think, that a certificate which was in use at the Home Office now was one that you would be satisfied with?—Yes. I only discovered it after writing my *précis*. That would be quite satisfactory to me.

12886. An alteration from the ordinary certificate to that is the alteration that you would recommend?—For certain heads of departments. I would like the Commission to distinguish, if possible, between the man who is the head of a department supervising the whole department, and a junior working under him as assistant or a research student. The head of the department is the responsible person. I have a department, and there will be men working under me in different directions.

12887. The head of the department holding a licence?—Surely. The head of the department holding a licence ought to have more liberty with regard to the range of work, always subject, of course, to the provisions for inspection and other things, than an assistant or research student should have, and a little more elasticity should be shown in this regard in the certificates by the Home Office.

12888. (*Sir William Collins.*) In regard to the interesting evidence which you have given us with reference to the antidote for arsenic by hydrated oxide of iron, did I correctly understand you to say that the use of that dates from 1861?—No, what I did say was that theoretically the iron was known as an antidote since the early thirties; indeed, between 1834 and 1840 the first experiments on dogs, I think, were made. The reference I have here is to experiments made on dogs between 1834 and 1840.

12889. Did not Bunsen point out the antidotal effect of hydrated peroxide of iron in the case of arsenic?—I do not know the date when Bunsen did it, but he only did it as a chemist would naturally, knowing the reaction between the iron salt and the solution of arsenic forming an insoluble arseniate of iron.

12890. But you stated that ever since the 1861 experiments this antidote had been recommended?—Yes.

12891. I suggest to you that it was recommended before 1861?—I should not like to contradict you, but if you take "Christison on Poisons" I do not think you will find Bunsen's name mentioned in connection with it. I am quoting from Christison just now.

12892. And I think you will. When was "Christison on Poisons" published?—The edition that I have is 1845, the 4th edition.

12893. Do you say that in that you will not find reference to Bunsen and Orfila and Douglas Maclagan making experiments with regard to the antidotal influence of hydrated oxide of iron on arsenic?—I certainly agree with you as to Orfila and Douglas Maclagan, but I cannot remember seeing Bunsen mentioned. Of course, to err is human, and I will not contest the point with you, but my recollection is that Bunsen's name is not mentioned; I may be wrong.*

12894. Should I be wrong in thinking that in 1845 or 1846 in Christison's work hydrated peroxide of iron was recommended as the antidote for arsenic?—Yes, it was recommended then.

12895. You state in your proof, I understand, that it was since 1861?—No, I think not.

12896. I have it here "Ever since that time," that is in 1861, "this antidote has been recommended to be used for human beings in such cases"?—Yes.

12897. I ask whether it was not recommended to be used in such cases prior to 1861?—I have no doubt that it was, and what makes me say that all the more freely is that in Christison's work the results of the experiments were so varied that Christison set himself to find out wherein the inconsistency lay.

12898. Was not the inconsistency largely a question of the quantity of hydrated peroxide used?—Very largely.

12899. Had not the fact that the inconsistency was due largely to the amount of hydrated ferric oxide used been clearly explained by Douglas Maclagan some time in the forties, showing that it was the amount of the dose that gave the varying results?—Yes. Christian made it quite clear, I think, at that time that it was merely a question of the sufficiency or insufficiency dependent on the quantity of the antidote in relation to the poison.

12900. That was known in the forties?—Yes, in 1845. Prior to that many of these experiments were made on dogs to which I referred.

12901. The experiments on dogs, I gathered that you referred to, were by Watt in 1861?—I mentioned other experiments on dogs between 1834 and 1840.

12902. I understood you to give us the date 1861 as the time from which the use of this ferric oxide had been recommended in the case of arsenic poisoning?—Yes, I know that since 1861 in every book on toxicology you will find the remedy given.

12903. But you are not so clear that it was not recommended before?—In some books it was, and in some books it was not.

12904. And in Christison you think it was?—Undoubtedly—I have no doubt regarding Christison.

12905. (*Chairman.*) Christison recommended it to be used by a physician when he came in contact with a case?—Yes, but I would like it to be understood without any doubt that Christison's opinion came after experiments on dogs conducted by M. Soubeiran, M. Miquel, and M. Boulay, and those researches were published in "Annales d'Hygiène Publique," volume XIV., p. 134.

12906. (*Sir William Collins.*) You did not think that Christison referred to Bunsen?—My memory does not serve me that Bunsen's name is mentioned, and I may say that I read over Christison on Saturday night.

12907. You also said that you had searched the literature of the world?—With regard to asseniuretted hydrogen.

12908. And it is a more limited research that you made in regard to arsenic?—I may say that I have here my book on the subject—"Toxicology and Public Health." I have a large number of references in it, and I have read very largely the literature on the subject.

12909. You have yourself conducted researches in forensic medicine?—Yes, many.

12910. But you have never had occasion to use vivisection?—I should not say that. There have been occasions when I should like to have had the advantage of vivisection.

12911. Have you had occasion to use vivisection yourself?—I have never used it.

12912. Then in such researches as have enabled you to enrich the subject of forensic medicine it has not been the result of vivisection by yourself?—No.

12913. You lecture, of course, in Glasgow on forensic medicine?—I have been a teacher of the subject for 25 years.

* *The witness subsequently wrote that he was wrong, having misquoted from his notes, and that Cristison does mention the name of Bunsen associated with the antidote in* 1834.

12914. Do you illustrate your lectures on forensic medicine by vivisection. I suppose you do not?—No, I have no licence, and I have had no accommodation for animals in my department in the University till the new buildings were opened in April of this year.

12915. In your opinion is it necessary to illustrate your lectures on forensic medicine by vivisection?—Surely not. I do not see any necessity for repeating experiments before a class with regard to poisoning, but I think it is essential that we should have facilities for legal work and work of that kind.

12916. You are aware that under Section 12 of the Act special provision is made for that?—Yes, I understand that that is so.

12917. (*Sir John McFadyean.*) With regard to this Certificate A, is it not a fact that the ordinary form of Certificate A bears that the research may be limited either as to the number of experiments or as to the time or as to both in the opinion of those who certify, and that considerable latitude is always allowed by the Home Office in regard to that?—The rubric on the margin of Certificate A, which I have before me, says that it may be given for such time or for such series as the person signing may think expedient.

12918. That is precisely what I wanted to bring out?—But may I add that the rubric further says, if the certificate is unlimited or limited by time only, the Secretary of State usually imposes a limit on the number of experiments to be performed; and I submit to the Commission that in Certificate A 2 there is no limit to the number of experiments put down.

12919. You think there should not be any such limitation?—May I put it in this way, that there are individual cases in which it is of the utmost importance, from a medico-legal and public health point of view, that the number of experiments should not be limited?

12920. That it should be large perhaps—would not that do? If you put down 500, for instance, do you think there would be any likelihood that the Home Office would override your opinion that that number was necessary?—It seems to me that there would be no advantage in doing that, because each investigator has to return the number of experiments he has made at the end of each year, and in any case the Home Office gets all the information with this advantage, that the operator is not limited as to numbers.

12921. (*Sir Mackenzie Chalmers.*) The existing certificate covers everything; it depends upon the form in which it is granted?—I do not wish to push this, but I never knew until recently that there were any other certificates than A, B, C, D, E and F; but I understand that there is a certificate called A 2.

12922. (*Dr. Gaskell.*) Would you read it?—This is a copy of the certificate which I saw. It is called Certificate A 2. The "2" has been put in in typewriting. It is headed "For Public Institutions." The number of experiments in that certificate is blank, and the time limit is blank.

12923. (*Sir Mackenzie Chalmers.*) To whom was it granted?—I prefer not to say unless the Commission desire it.

12924. (*Mr. Ram.*) Was it from the Home Office?—Yes.

12925. (*Sir Mackenzie Chalmers.*) Not granted by the Home Office; the Home Office do not grant certificates; they are approved by them?—It was not given to Sir Thomas Stevenson, I may say.

12926. (*Sir John MacFadyean.*) Is it possible that the figure "2" is merely to distinguish that particular Certificate A from a previous Certificate A given to the same holder and held at the same time?—That I cannot say.

12927. I suggest that it is. However you are satisfied with that form?—May I read the kind of range of work that is permitted under this certificate?

12928. Certainly?—"Hypodermic intra-venous and intra-peritoneal injection of living cultures of bacteria, bacterial poisons, chemical substances, animal and vegetable extracts, blood and other medicinal poisonous and infective substances. These injections may be repeated at intervals and in various combinations. Immunisation experiments with any of these substances may be performed. Inunction into the skin and administration by the mouth of bacteria animal extracts and vegetable substances. From time to time during the experiments small quantities of blood, peritoneal fluid or other exudation may be removed for examination." That is the range of work covered by that certificate.

12929. (*Sir Mackenzie Chalmers.*) Is that the original certificate given, or is it the certificate as confirmed by the Home Office?—It is a copy sent from the Home Office with the stamp of the Home Office on it.

12930. (*Sir John McFadyean.*) That is precisely the form of certificate you would approve of to be given to heads of departments?—This is the kind of certificate I would like to have, and will apply for, because it seems to me that it is the only kind of certificate that would cover the range of work I am asked officially to do.

12931. You mean that otherwise some case might turn up that you would be really unable to investigate owing to the circumstances not having been precisely set forth in your certificate?—Yes. Supposing, for example, I put in a certificate thinking that I would have a certain number of experiments to perform, and named my animals and omitted to mention a rat, I should not with that limiting certificate be able to do an experiment on a rat without a new certificate.

12932. I wanted to ask you another question with regard to the necessity for animal experimentation in supposed cases of meat poisoning. As you mentioned, Gaertner's bacillus is frequently the offending microbe in these cases. In your opinion is it often or generally quite necessary to resort to experimentation on animals in order to prove that the case is really one of infection with Gaertner's bacillus?—I should not think it needful in every case where Gaertner's bacillus was found in the offending meat where it could be proved.

12933. That is just the point I wanted to raise. Can you tell the Commission whether Gaertner's bacillus can be recognised for a certainty from its morphological characters and the appearance with which it grows in cultures?—Gaertner's bacillus can be differentiated from the other two groups in the Coli series by cultural tests; but there is a series of organisms in the Gaertner group, the enteritidis group, that we cannot differentiate culturally.

12934. So that the answer to my question would be "No"; that in order to be sure that you have got the Gaertner's bacillus you must prove its pathogenic power?—Precisely. I have a long list here of food epidemics caused by micro-organisms to which I could easily add.

12935. I would like to repeat the same question with regard to sausage poisoning, that is to say, the effects produced by the bacillus botulinus. Should I be correct in saying that the bacillus botulinus really cannot be with certainty recognised without animal experimentation?—I quite agree with you in saying that the bacillus botulinus cannot be recognised without animal experimentation.

12936. It operates simply by the poisons which it generates in the meat?—Yes, the toxin does.

12937. So that you cannot prove that a particular parcel of meat is really the cause of illness in this way except by showing that it is capable of producing toxin effects when it is injected into animals?—That is the kind of evidence that I would be inclined to offer if I were asked to give evidence at all with regard to the toxic effect of meat. May I add with regard to Gaertner's bacillus that it is an open question yet whether the toxins are destroyable by boiling temperature or not. The latest investigations show that they are not, and that you might easily get the toxins of this bacillus in meat, there being no organism at all, and still fatal results and a serious outbreak arising.

12938. (*Mr. Ram.*) Although boiled?—Although boiled.

12939. (*Sir John McFadyean.*) Do you see any way of settling whether the poison can be destroyed by heat without animal experimentation?—I think we might easily discover some laboratory method, but it is another thing in practice with regard to public health, because the people take the meat or the soup not knowing the thing is there. If they knew it they would not take it.

12940. Can you suggest some way in which it might be proved that the toxin has been destroyed, without having resort to animal experimentation?—I cannot at the moment suggest any method in the case of meat by which you could destroy its toxin.

Mr. John Glaister, M.D.

23 Oct. 1907.

12941. It is not as to how you would destroy it, but as to how you would know it was destroyed?—The only way is by experimentation on animals.

12942. Is anything known whatever about its toxin apart from its effects?—Nothing, except that it is very poisonous, and there is no doubt about it.

12943. With regard to some experiments to which I referred earlier carried out by Dr. Stuart McDonald with regard to cerebro-spinal meningitis, I rather understood you to say that the results of his experiments on monkeys were of little value as showing the way in which the disease is contracted in human beings?—No, as showing the way in which the disease was spread, was my language.

12944. That is the same thing?—I think not. When you are thinking of spread, you are thinking of how the disease may be communicated from place A to place B. Physiologically between the anthropoid ape and the human being, so far as taking the disease goes, there is no difference.

12945. Would you admit that these experiments were of great value as bearing upon the question whether man is infected by ingestion?—Yes, certainly. I was not animadverting on that. I was regarding the spread solely.

12946. Coming to the question of what really led to the introduction of hydrated oxide of iron as the antidote to arsenic, although there were chemical grounds for believing that it would act as an antidote, do you think that the custom of administering it as the antidote in human beings would ever have become universal if we had not been provided with experimental evidence such as you have referred to?—I think it is hardly likely that any man would have ventured to apply this antidote for the first time to a human being before he had seen how the thing would act on animals.

12947. So that you feel confident that these experiments had much to do with making the administration of this particular substance practically universal in cases of arsenical poisoning?—I have no doubt of it at all.

12948. (*Sir Mackenzie Chalmers.*) About how many cases of suspected poisoning do you have in a year in Scotland?—We have not very many.

12949. Half a dozen or a dozen, would you say?—You see we never know until we investigate them whether they are cases of poisoning or not; in many instances we have to make an investigation in the first place before arriving at a conclusion.

12950. Have you ever known of cases where that investigation or conclusion was impeded or delayed from want of a certificate?—No, I do not put that forward.

12951. You are aware that in any case of difficulty, without going to the Home Office, a judge of the Court of Session has power to order any necessary investigation?—That is quite so; I am aware of that.

12952. I take it that your point is this, is it not, that you think that the head of every important laboratory ought to have the wide form of Certificate "A," instead of the restricted form confining him to a specific number of animals and a specific time?—My answer is "Yes," for this reason, that if you take, for example, food poisoning, in which there may be questions of culpability arising, before you can get a certificate from the Home Office, even supposing you follow your suspected meat, your evidence is gone.

12953. You mean that the investigations must be made at once, or they are futile?—They must be made at once if they are to be of any value.

12954. Are there not plenty of people in Scotland holding the necessary certificates to cover any case that has actually arisen?—But it would be no use to me if I had not got it, and I was asked to conduct the investigation; and it is because of the variety of problems one has to deal with as head of the Department that one would like such a certificate.

12955. (*Chairman.*) You said the head of a department and the head of a laboratory; do you mean the head of a laboratory in a public department?—Yes, I mean that. I should say the head of a department, because in my Department of Forensic Medicine and Public Health I have several laboratories under my care.

12956. (*Sir Mackenzie Chalmers.*) You are not aware really whether there has been any difficulty in the head of a department, properly certified, obtaining the necessary certificates?—I do not think so. I think that the Home Office is exceedingly generous. The only difficulty that I have is this, and I would like to put it here, because I may have to salve my conscience and get the Commission, as a Royal Commission can do, to give me an indemnity if I have been wrong. I want to say what I have done. There is great difficulty felt by many of us in being able to determine what really is an experiment under the Act, and there is great difficulty also in defining what is pain under the Act. According to Section 2 a person shall not perform on a living animal any experiment calculated to give pain, except subject to the restrictions imposed by the Act. I want to ask the attention of the Commission for a moment to feeding experiments. It seems to me a ridiculous thing for a man who proposes to feed a cat on cow's milk to have to go to the Home Office for a certificate. I have interpreted the Act differently, and I have acted accordingly, as I shall show immediately. The effect of that on the public mind is this. If that practice is to be followed the total number of experiments at the end of a year is so increased that the public sensitive to this thing think that vivisection is enormously on the increase. I would like to refer in corroboration of what I have said to Questions 205, 206, and 207, which indicate that even in Mr. Byrne's opinion certificates are asked for which, in the opinion of the Home Office, although they would not offer any opinion of that kind, seem to be unnecessary with regard to feeding. Now, three years ago I was asked to deal with the following problem. A series of cows were alleged to have been poisoned with draff, that is, distillers spent grains, on account of minute proportions of arsenic present in the draff and found on analysis. The amount of arsenic found per lb. of draff was between 1-500th and 1-600th of a grain. The people who had to deal with that action had had no opportunity of seeing the animals during the continuance of this so-called poisoning. The animals were dead; they had no opportunity of seeing their bodies at a *post-mortem* examination. I was consulted by the people and asked—What are we to do? I said—It is no good our going to court and simply swearing to a negative, that this amount of arsenic would do cows no harm. The only evidence of any value for the guidance of the court was to give arsenic to cows over a lengthened period, because we knew that the arsenic, to be so given, would do no harm. Accordingly the Principal of a Veterinary College, a Fellow of the Royal Veterinary College, and an examiner of that college, a colleague in the University, and myself agreed that we should feed a series of cows on arsenic doses much larger than these over a period of three weeks. We did not feel that we were under the Act. We knew that the arsenic would do the cows no harm, but would do them good. We selected a bull and two cows, each with sucking calves. We gave each adult animal a quarter of a grain of arsenic three times a day for the first week; we gave them half a grain of arsenic three times a day for the second week, and we gave them a grain of arsenic three times a day for the third week. Thus in three weeks we gave these three adult animals 36¾ grains of arsenic in addition, of course, to the draff as their food, which was blamed as being the cause of the mischief. We weighed the animals at the commencement of the investigation, and their temperature was noted during the currency of the investigation night and morning, and at the end of the experiment every animal had increased in weight. This evidence was given to the court, and the court gave its judgment on that ground; and I hold personally that we were without the Act making that investigation.

12957. (*Dr. Wilson.*) Arsenic is often given to horses?—Yes. Then I may take another case. I am many times consulted with regard to rivers pollution cases in Scotland, and, as the legal members of the Commission will know, Part III. of the Rivers Pollution Act deals with what is called noxious poisoning or polluting liquid. The County Council of Lanarkshire asked me to advise them with regard to an alleged occurrence of this kind, and I made an analysis of the river water above and below the point of effluence of this liquid, but it is impossible to convey to the mind of a court of law whether a thing is noxious or poisonous unless you get some evidence to show that it is noxious or poisonous. I could not ask the court to go and look at the plants in the river, and I did not expect that the court would be able to understand fully the chemical analysis, consequently I did the third best thing. I made an investigation on fish; I carried

through an investigation on fish in the different effluents, and I published the results in the Philosophical Society's Transactions in detail.

12958. (*Sir John McFadyean.*) Were the fish transported from healthy water and put into that water?—Yes, they were; they were got from a hatchery, as a matter of fact. The gold fish were bought at a fishmonger's, and the minnows I got caught in the river. I used gold fish and minnows, one-year-old trout, and trout of two years old.

12959. (*Sir Mackenzie Chalmers.*) Did they all increase in weight and happiness?—No.

12960. (*Mr. Ram.*) Did they all die?—Some of them died, certainly.

12961. (*Sir John McFadyean.*) On what ground do you conclude that this was not an experiment?—I thought that nobody would contend that fish, being cold-blooded animals, could at all be ranked with regard to pain on the same level as warm-blooded animals.

12962. Under the Act, do you mean?—No, it is a question of interpreting the word "pain." A definition of "pain" is what I want to get at. Nobody will define "pain" for us. The Home Office very properly decline to do so. The individual certifier to whom you apply has to do it for himself. I have never been able to look upon fish, from my knowledge of fish as an angler and in other ways, as on the same platform at all as warm-blooded vertebrate animals.

12963. (*Chairman.*) You will not expect us to offer an opinion as to whether this came within the Act or not?—No. I want to be quite frank, and I say that I am mentioning these cases in order to get the protection which the Commission, being a Royal Commission, can give me if I have gone outside the Act.

12964. (*Mr. Ram.*) As I gather, all these experiments of which you have told us as to cerebro-spinal meningitis and as to these noxious gases, all those which you decided to perform or did perform you could perform under the Act as it stands to-day?—Yes, they can all be performed under the Act as it stands to-day. My point is that these questions have relation to asking the Commission not to limit the powers which they presently give us, but in the case of heads of departments to somewhat increase them.

12965. I am coming to that. This evidence of yours, so far as I have alluded to it now, is in order to induce the Commission not to recommend narrowing the powers conferred by the Act to-day?—Precisely, that is the object of the evidence.

12966. The only suggestion that you make as to an alteration of the law is to extend, at any rate to heads of departments, such matters as are dealt with in what you call Certificate A 2?—Yes, that is, of course, where one has to deal with a variety of problems rapidly and very often for the guidance of Courts of Law.

12967. Whether that can be done under the Act as it stands to-day or not. If it cannot be done under the Act you are content if such matters as are described in that Certificate A 2 were given to heads of departments?—Yes, so far as I can see, I think the Act would then be quite excellent.

12968. (*Dr. Gaskell.*) I only just want to ask one further question with regard to that point, as to which I am not quite clear; that is, do you limit the word department to any special department in each place, in each University or town, or would you include in your term heads of departments the heads of all those places that are licensed?—My intention in using the word department was to convey this, and I can illustrate it by a concrete case. In every university there are departments in which experimentation is usually carried on; the Pathology Department, for example; the Forensic Medicine and Public Health Department, and the Pharmacology Department may be taken as types.

12969. And the Physiological Department?—I beg your pardon—the Physiological Department. There are four. There may be under each of these departments several laboratories. You may have assistants, you probably will have them in each of them; you may have research students in some of them. What I desire the Commission to understand by my position is that the head of the department, that is, the professor in charge, should have the fullest facilities, that the assistants should have limited facilities such as now exist under the Home Office, and in the same way research students would have perhaps, to a still more limited degree. The professor at the head of the department ought to be looked upon as the responsible person, who would naturally in his returns let the Home Office know exactly what he was doing.

Mr. John Glaister, M.D.
23 Oct. 1907.

12970. That is what I wanted to get at. The head of the department, whom you would entrust with these further powers, might be the head of any one of those various departments, the head of the Physiological Department or the Pharmacological Department, or what not?—Surely.

12971. It is not for the particular Forensic Medicine Department that you ask it?—No. I may say that now the heads of departments are responsible for the conduct of the departments. They would be practically responsible, if, for instance, they had an assistant or a research student in them, because the animal house is under their control and under their charge.

12972. (*Sir Mackenzie Chalmers.*) You would make the head of a department responsible for any misconduct that went on in his laboratory by his assistants?—Surely, so far as he could control it.

12973. (*Mr. Tomkinson.*) In the investigation of poisoning, such as in Lamson's case, which you have to make and in which you say the discoverable amount of poison is so minute as to be hardly traceable when discovered, and used for experiments upon animals, I suppose you would be content with, you would necessarily have to use a very small animal, like a rat?—Yes. May I say that in the cases I have mentioned the difficulty does not commence at the experimentation on the animal? Before you can do that you have to isolate the substance which is to be injected into the animal from the whole mass of these organs, which is a very laborious business. You require to take the internal organs very largely, and get the poison extracted from those first, before you can use it upon animals.

12974. Where does the experimentation previously upon living animals help you to discover that very small and difficult amount to be discovered?—Assuming, for example, that I carry out a series of experiments on that poison, aconitin, which was used in the Lamson case, supposing I use it upon rats and mice I can see exactly the effect produced by the result. If I get in a rat or a mouse from something extracted from a human body which is dead, symptoms corresponding to those same symptoms in the animal, then it is fairly strong confirmatory evidence that I am dealing with the same poison.

12975. You judge by the symptoms?—Yes.

12976. But if the symptoms developed by the animal by a very minute portion of the poison discovered, tally exactly with the symptoms under which the human being died, that is naturally good evidence, but it does not meet your point which you put to me at first when you said that that was not the difficult point. A poison once discovered it is easy enough to test it upon a small animal?—I agree, but the trouble in these cases is getting the poison from the human body to test it upon the animal.

12977. But how are you helped to find that very minute portion?—You are not helped at all, so far as the animal is concerned, in the preliminary stages. You are only helped by the animal at the closing stages of the inquiry, namely, the detection of your poison, which is the important point.

12978. (*Sir John McFadyean.*) I think the question was, where are you to get the poison, which is not necessarily isolated. I suggest that you use as much of the corpse as you can?—I have just been explaining that. You use so much of the internal organs of the body to isolate the poison.

12979. (*Mr. Tomkinson.*) But are you helped to discover that poison by previous experiments on animals?—Surely; you could not make comparisons unless you had made previous experiments on animals with the same poison, and, as I said, assuming that you use aconitin upon rats and mice, knowing that it is aconitin, and you get the development of certain clear symptoms, then, if you get something extracted from a dead body which, when injected into a mouse or a rat, produces the same symptoms you have got strong confirmatory evidence of the fact that the same poison has been used.

12980. (*Dr. Wilson.*) You attach the greatest importance to animal experimentation, both in public health and in criminal cases?—Yes, in certain departments of each of those.

Mr. John Glaister, M.D.

23 Oct. 1907.

12981. And you have been engaged in that sort of research for the last 25 years?—Yes, I have been engaged in researches, without experimentation on animals, for the last 25 years.

12982. And without, of course, as you say, having had any licence?—Yes.

12983. Should I be right then in inferring that you have been able to carry out all those researches and investigations, and I know that they are very difficult investigations and researches, without the aid of animal experimentation?—No, I have not been able to carry them all out.

12984. Could you name instances to the contrary?—Food poisoning cases, for example, would have been done either in the Corporation's Bacteriological Institution, which is licensed, or when one has had an investigation to be carried out, one has had to apply to somebody who had a licence and assume it as his own experiment.

12985. But have there been any cases of illness in which you have had to enlist this additional assistance as it were?—No, I have had very few cases. Fortunately, it is only the expert poisoner who would use the alkaloids for the purpose. An ignorant man has not a knowledge of them. He may use strychnia, as happened in a recent case, but then we can detect that by chemical means; we do not require experimentation on animals except with small quantities, and then we use a frog—Marshall Hall's well-known test.

12986. Has it not been proved by recent research that even sound food, during the process of healthy digestion is broken up in part, or in whole, into these poisons that you talk of—ptomaines and alkaloids?—You mean in the living stomach?

12987. Yes, in the living stomach; that that is the first process of healthy digestion and with wholesome food?—Before I could answer that I would require to know exactly what you mean by ptomaines, because the word ptomaine itself implies that it can only be formed in a dead body.

12988. Yes, I know; but as you know, ptomaines are formed, at least it is contended that they are, both ptomaines and leucomaines, by the decomposition of healthy food when it is attacked by micro-organisms. The food is dead, of course, when it gets into the stomach?—Yes.

12989. Then would you not expect on analysis to find a certain amount, at all events, of these deadly alkaloids and poisons in all food that has been kept for some time, whether flesh or fowl?—I do not think that the present stage of science would enable me to give a definite answer to that question. Brieger and others have isolated alkaloids from dead tissues which were poisonous to animals, and there can be no doubt that there is a difficulty sometimes in determining in the examination of a dead body, whether the poisonous principle that is found has been due to the substance swallowed or to the natural result of decomposition of the body. That is the difficulty, and it is in order to enable science to deal with such difficulties that experiments are carried on.

12990. Then if it is possible to find these ptomaines in animal food that has been kept for some time, you would expect to find them in still greater volume in, for example, venison or game, which is always somewhat high, and yet is edible?—I think that all those foods which are eaten high have their special risks.

12991. Because they contain ptomaines?—Yes.

12992. Then with regard to all these food outbreaks, such as from eating sausages, and so on, the poisoning called botulism, is it not possible to ascertain with certainty that all these outbreaks have been caused by the food?—No.

12993. Or by the condition of the food?—No, if you take, for example, Gaertner's bacillus, of which we have been speaking, you may get meat containing this organism which neither by smell nor appearance nor taste would give any indication of the presence of the organism. It is not a putrefactive organism in that sense; it does not cause a nasty smell, it does not make the meat look bad, consequently it may be taken quite innocently or purveyed quite innocently in the belief that it is good food.

12994. Do you say that Gaertner's bacillus is not a putrefactive organism?—Not in the bacteriological sense, as we speak of putrefactive organisms.

12995. I will put the question in this way then. We will suppose that you have isolated these ptomaines, some from the corpse, some from food about which I have been speaking, either game or meat that has been hung for some time, could you then distinguish between the ptomaines that have been obtained from the ordinary healthy butcher's meat or venison and the ptomaines which have been obtained from the decomposition of the dead body?—Do I understand you to mean healthy butcher's meat?

12996. Meat that has been kept for some time?—I would not call it healthy meat if it has been kept till it is high.

12997. I will say venison then, which can be eaten without doing any appreciable injury?—Venison is usually kept until it is fairly high before it is eaten.

12998. Will you assume then that ptomaines can be obtained from ordinary butcher's meat that has been hung and cannot be condemned as unwholesome, and can also be obtained from game or venison?—In the case of all flesh foods, no matter of what kind, if they are kept until they are high, it means simply that they are undergoing putrefaction, and there are risks attending their consumption because of the presence of these toxin or ptomaine substances.

12999. But you could not differentiate by experiments on animals between ptomaines derived, say, from butcher's meat that has been hung, and yet could not be pronounced to be unwholesome, and ptomaines derived from a dead body?—There is this source of differentiation with some of them. It would be correct, I think, to say that many of the toxins formed in the way we have been discussing would be destroyed by a temperature of boiling point, but that some others of them would not be so destroyed, and among these particularly that of Gaertner's bacillus. That is about the only way in which I can determine the difference between them up till now so far as science would enable me to distinguish them.

13000. Is not Gaertner's bacillus—that is to say the bacillus enteritidis—found almost anywhere where there is decaying vegetable or animal matter?—Not by any means always.

13001. But generally?—No, I would not say even generally; it is exceptional; that is the reason why meat poisoning outbreaks are so uncommon, considering the great use of meat in this country as compared with other countries. We do not eat our meat raw in this country; they do largely on the Continent, and if this Gaertner's bacillus be present in meat they are liable to have outbreaks on the Continent, as the evidence shows.

13002. Do you attach the poisoning of food then to the presence of the bacillus?—All the outbreaks which I have been speaking of were believed to be due to this Gaertner's bacillus or one of its allies in the same group.

13003. You have referred to the cerebro-spinal meningitis disease and to the passive carriers of the meningo-coccus. Has it not been proved lately, by Dr. Gordon, one of the experts of the Local Government Board, that very little reliance can be placed upon the examinations which have been hitherto made with regard to the presence of the bacillus in the excretions from the mouth?—The latest work that has been done on that is this: it is quite likely that the witness may be here, but I can anticipate his coming, if he does come, by stating the fact that within the present year an examination has been made individually of 370 contacts, that is to say, persons coming in contact with cases of cerebro-spinal meningitis in Glasgow and the results are as follows:—Of the 370 contacts 22 are to be deducted, for one reason, and in all, including these, 62, leaving for consideration 308 cases, occurring in 74 families. The meningo-coccus was found in 81 of these, or 26.3 per cent., that is to say that in 81 people out of 308 who came in contact with cerebro-spinal meningitis, but who themselves were not affected by it, in their upper air passages the meningo-coccus is proved by bacteriological examination.

13004. But has it not been demonstrated by Dr. Gordon, because I have just been reading his Report to the Local Government Board, that this meningo-coccus has been confused in these passive cases to which you are referring with the ordinary micro-coccus catarrhalis?—No, I tell you that this investigation was intended to bring out the difference between the micro-coccus catarrhalis and the meningo-coccus; there is a

characteristic difference between the micro-coccus catarrhalis, which makes it different at once from the meningo-coccus. The difference is this: if you take a particular medium, that is to say, a material containing neutral red, the meningo-coccus produces an acid reaction; the micro-coccus catarrhalis does not, and that is a very marked distinction. These investigations were based upon that difference, and other differences obtained culturally.

13005. But do not you think that the difficulties attending such research are so enormous that errors are liable to creep in?—Precisely, and it is because we want to eliminate these errors that we hope the Commission will not do anything to prevent our being able to do so, but will give us more facilities.

13006. You think experimentation on animals the final court of appeal on all these points?—Yes, in this respect, that I think we can hardly use human bodies. I think the medical profession and scientific men have not spared themselves in investigations, but there are certain others that we cannot ask them to perform upon themselves.

13007. I will put it in this way. You have been talking about scientific poisoning. Supposing in the Lamson case a needle had been used instead of the poison being given by the mouth, do you think the poison could have been discovered by any process?—It would have made no difference. In either case the aconitin would have been absorbed into the circulation, and have to be recovered from the organs. The mouth administration had nothing to do with it.

13008. Do you attach as much importance to the result of experiments by the mouth as Stevenson did on applying the extract to his lips?—I think that aconitin has such a peculiarly characteristic numbing effect upon the mucous membrane of the lips and the tongue, that nothing else could be mistaken for it.

13009. That of itself was conclusive—the mere testing on the mouse was at the very outside only a slightly confimatory test?—But may I put it in this way: before Dr. Stevenson could apply this test to his lip or his tongue he had to isolate this extract from the organs of that dead man; there were weeks of labour in that alone.

13010. But I mean in testing the extract?—The testing was the easiest part of it.

13011. It was not necessary really to test it on the mouse; was that of any value?—It was of this value that the infinitesimal amount injected into the mouse could produce the symptoms of poisoning by aconitin. A touch on his tongue could not produce them, but it could poison the mouse, and the mouse showed the toxic symptoms, and thus corroborated the test he originally carried out on his own tongue.

13012. But it would not have been considered a conclusive test of itself. By injecting aconitin into a mouse you could not say without any other experiments that the substance was aconitin?—I am afraid I do not follow your question or your reasoning. If I take the substance I extract from a plant in my garden called monkshood, and inject that principle into a mouse, and the mouse shows evidence of poisoning, surely there is no difficulty as to the cause and effect.

13013. But are the symptoms always the same?—Yes, the symptoms generally are the same.

13014. Have not experimenters differed greatly as regards the results that they have obtained by various testings?—Solely because different plants of monkshood contain different proportions of aconitin; that is the only thing. Every plant does not contain the same percentage proportion of toxic material; that is the only difference.

13015. I think you admitted that you do not perform experiments on animals to illustrate your lectures?—No, and I never should. I do not think in my work I should do it. I am speaking personally. I am not saying that other men may not require to do it. I am only saying that so far as I am concerned I should not use animals to illustrate my lectures.

13016. But in illustrating the action of poisons do you think it is necessary, in order to teach the students?—No, I do not think I should do it personally.

13017. Or to illustrate the physiological action of medicines?—I have nothing to do with the physiological action. I am beyond the physiological stage, the toxic stage.

13018. Then, of course, I need not ask you whether you support what is called seropathy right through—serum-therapy?—I am quite convinced that nothing has made such a vast alteration in the death rate from diphtheria as the serum treatment of diphtheria. I do not think that any medicinal treatment could have been devised which would ever have effected what this serum treatment has done for diphtheria.

13019. You think it can be regarded as a sort of sheet anchor now in the treatment of the disease?—I have not the remotest doubt of it.

13020. What about serum therapy in cerebro-spinal meningitis?—That has not been so uniformly successful; the anti-meningo-coccic serum has not been so successful.

13021. Has it been successful at all?—In some cases there has been a cure, but I do not know whether you can say it is cause and effect quite so positively as in the case of the serum anti-toxin in diphtheria.

13022. But the anti-diphtheritic serum is the only serum that has been attended with what you might call success?—If you are dealing with the preventive material used in the prevention of anthrax then that has proved an enormous benefit to the world.

13023. I am speaking of sera?—I claim that about anti-toxin.

13024. (*Dr. Gaskell.*) May I ask one question with respect to what you said just now. Do not you think it is advisable for students to see, for instance, the action of strychnia. When you say that you would not show students any experiments, would you not show them experiments in which the animal was completely under anæsthesia?—I must qualify my last answer by the fact that if the animal was under chloroform then the experiment would be of no use.

13025. Not necessarily, might it not be with certain alkaloids?—Chloroform would mask the action of alkaloids you see. The only treatment for strychnia poisoning is chloroform.

13026. Naturally. I was not speaking of strychnia then; I was speaking generally. As regards the action of digitalin, for instance, or many other poisons, would you not show experiments?—You could not show an experiment on digitalin with an animal under chloroform; it would obviate the effect. The only experiment in a criminal case where digitalin was suspected of having been the poison was a case occurring in France; the animals used there were frogs without any anæsthetic at all. That was Tardieu's case. That is the only case in which an experiment with digitalin could be conducted in order to show true results.

13027. What I want to get clear about is this, that the experiments showing the action of various alkaloids and so on you would rather leave to the Pharmacological Laboratory?—That is so.

13028. That is what I understand. It has not come into your department as teacher of forensic medicine? No, because the doses that I give are toxic—fatal.

13029. (*Dr. Wilson.*) I think I gather from what you have just said that anæsthetics interfere very considerably with the results which you would otherwise obtain from the administration of many of these drugs and poisons?—Poisons not drugs. If I want to see the true natural action of a poison I do not want to administer another substance which may act poisonously at the same time and confuse the results.

THIRTIETH DAY.

Tuesday, 29th October 1907.

The Right Hon. The Viscount SELBY (*Chairman*).

Sir W. S. CHURCH, Bart., K.C.B., M.D.
Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir J. MCFADYEAN, M.B.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. A. J. RAM, K.C.
Mr. W. H. GASKELL, M.D., F.R.S.
Captain C. BIGHAM, C.M.G. (*Secretary*).

Mr. STEPHEN FRANCIS SMITH, M.R.C.S., called in; and Examined.

Mr. S. F. Smith. M.R.C.S. 29 Oct. 1907.

13030. (*Chairman.*) You are a member of the Royal College of Surgeons?—Yes.

13031. And you are Surgeon to the Anti-Vivisection Hospital?—Yes.

13032. And author of two works on vivisection, "Scientific Research" and "Fruitless Experiments"?—Yes. I may mention also that I am a member of the International Medical Anti-Vivisection Association.

13033. I do not quite understand what the Anti-Vivisection Hospital is. I do not understand its title. Does it mean that no operation is performed there upon animals—that there is no laboratory or anything of that kind; or does it mean more than that?—Primarily it is a hospital; secondarily it has been founded by anti-vivisectors, who took that opportunity to make a kind of public protest against vivisection by the name which they gave to the hospital.

13034. That is to say, it is supported by anti-vivisectors. That is practically what it means?—Yes.

13035. In the treatment of patients you use the usual remedies, I suppose, used in other hospitals?—We do not bar anything that will do the patient any good.

13036. You do your best to cure your patient with whatever remedy is most suitable?—Yes.

13037. That, I suppose, applies both to surgery and to medicine?—Yes.

13038. You have formed an opinion as to the amount of sensibility of animals to pain as compared with man, I think?—I should like to mention first the evidence from special senses in the lower animals. We find that the sense of smell is stronger in many of the lower animals than in man; it is well known to be the case in dogs; and from travellers' accounts of hunting game the scent is stronger in them. I have read in many travellers' accounts of travels in South Africa that their oxen would smell water at a long distance, and very much to the surprise of the travellers. As regards sight, it is well known that vultures can see at an enormous distance, and although that may depend partly on the structure of the eye, yet without a highly developed sensitiveness in the retina, and in the brain centre to which the visual impulses are conducted, that structure of the eye would be comparatively useless. As regards hearing, I have found in my own dog that it has a very remarkable power of hearing, far greater than that of any human being. What I wish to point out is, and I am going to show presently, that there is a widespread belief that sensibility to pain depends upon intelligence; but here I simply wish to indicate that if that theory were correct it would prove that the lower animals could not smell, hear, and see as they do. Next I wish to say something about the teaching of biology and evolution. Wherever a sense or structure is necessary to the preservation of the animal, that sense or structure will be highly developed. Pain has a function. The greater the sensibility to pain, the more care will the animal take to avoid danger and preserve life. Pain is a more important factor to the lower animals than to man. Man, inferior in the special senses which warn him of danger, inferior in strength, speed, and natural weapons to many of the lower animals, makes up for these deficiencies by intelligence. Similarly, his intelligence guards him to some extent against danger, and there is less need for acute sense of pain. We have also the teaching of psychology. There is a popular belief that pain varies with, and depends on, intelligence. This view is contradicted by the evidence of the special senses I have mentioned, and lands us in the absurdity of having to believe that a man can smell more keenly than a dog. It is contradicted also by psychology, which tells us that the higher thoughts and feelings are due to the compounding and recompounding of the simple sensations, while the popular view, on the contrary, is that the simple comes from the complex. I wish to point out that the only right principles on which we can form a conclusion as to pain which the lower animals feel is by taking into consideration the surroundings of the animal; that is, if pain is necessary to the survival of the animal we may conclude by all analogy of evolution that the sense of pain will be highly developed.

13039. I should just like to follow what you mean by the evidence of the special senses. There are some savage races which have a much acuter sense of smell and sight than some civilised races, are there not?—Probably, yes.

13040. Do you think that those savages have necessarily a more acute sense of pain?—Not necessarily. But in the case of a savage there may be something in the surroundings of the savage which make it necessary that the sense of sight should be highly developed, and possibly, though I do not know, about the sense of smell. But it is said that Arabs have long sight, and it may be necessary, or was necessary in the ancestor of the Arab, that he should have long sight in order to see an enemy at a long distance; I would simply point out that his sight was modified to his conditions of life; but I was specially comparing these evidences of special senses with the belief that sensation is proportioned to the intelligence.

13041. Would you say that of different races of men? Would you say that the sensation of the negro in West Africa is more acute than that of a civilised man or as acute?—It might be very difficult to judge directly; but if pain has been necessary to the preservation of the negro I should say that it would be as well developed in him as in civilised man.

13042. You would not say that such a negro in his wilds was equal in intelligence to a cultivated white man in England?—No, I should think not.

13043. But you think his sense of pain would be the same?—I should think so.

13044. (*Sir Mackenzie Chalmers.*) Greatly increased, ought it not to be?—It ought to be greater.

13045. (*Chairman.*) You think it is greater?—I should think probably it is greater. But I should like to mention my own experience as regards different classes of people. In my occupation it has been my business to inflict a good deal of small pain without anæsthetics on patients, and I have never been able to observe any difference between my hospital patients and private patients. I spoke to a dentist—a dental surgeon to a hospital—and asked him his opinion, and he said he thought there was no difference—that the only difference he could see was that hospital patients gave greater manifestations of pain.

13046. I was interrupting you rather. Have you said all that you have to say on that question?—I was going on to say that it is obvious that if this untenable belief is held by physiologists it is a danger to animals under experiment. I therefore give evidence that such belief is held. Some years ago I received some literature from the Secretary of the Association for the Advancement of Medicine by Research. In it was a pamphlet by an anonymous writer, maintaining that the lower animals are less susceptible to pain by reason of their less intelligence. I was for some time at the Pasteur Institute in Paris. I observed laparotomy (opening of the abdomen) performed on rabbits without anæsthetics. I spoke to an American medical man who had been for some years in the Pasteur Institute, and asked him why an anæsthetic was not given, and he told me it was because the rabbit did not mind the operation. He was not making a joke; that was his genuine opinion. I give the opinions of some English physiologists, Professor Huxley and Dr. Anthony, who, at the last Royal Commission, maintained at Questions 2547 to 2560, that animals do not feel pain as we do, and that their struggles are mere automatic or reflex movements. Similar opinions at the same Commission were given by Dr. Pavy and Dr. Pye-Smith.

13047. Do I correctly understand you to say that Professor Huxley said that all struggles by animals, when painful operations were being inflicted upon them, were merely reflex movements?—I think it was left somewhat indefinite. I do not think he said all.

13048. I see he was asked: "So that an operation which is constantly performed on sows in order to get them to fatten a little faster is an operation decidedly more painful than that which you say is carried on for scientific purposes (that is spaying)," and the answer is, "Yes." That is Dr. Anthony giving evidence and Professor Huxley asking the questions?—Yes, he was asking leading questions.

13049. I will not read through the whole of the questions and answers that you refer to, but perhaps some other member of the Commission will have an opportunity of examining you upon them. That is what you say is the effect of his evidence?—Yes. I was going on to say that similar opinions at the same Commission were given by Dr. Pavy, Dr. Pye-Smith, Dr. Burden Sanderson, Dr. Crichton Browne, Mr. Schäfer, Mr. (now Lord) Lister, Professor Humphrey, Dr. McDonnell, Dr. Cleland, Dr. Sibson, Mr. George Henry Lewes, and, in the *Nineteenth Century* of December, 1881, by Sir James Paget.

13050. And all these gentlemen, you say, were of opinion that animals feel less?—Yes.

13051. (*Sir Mackenzie Chalmers.*) Do they give reasons?—No, I think not.*

13052. (*Chairman.*) I suppose they were asked questions about it, were they not?—I do not think they were. Dr. Cleland said that it was doubtful if frogs feel at all, and would therefore no more think of anæsthetising a frog for an experiment than a worm for fishing. (That is at Questions 4615 and 4616.) It was admitted by Dr. Sibson (Question 4752) that he had no ground for believing curare an anæsthetic, but had employed it as such in painful experiments.

13053. As to curare, I think everybody who has been before us has admitted that curare is not an anæsthetic?—That is not the point that I am referring to at present.

13054. It is what you were reading?—Yes, but it has reference to what I am going to say in a moment. There were similar admissions from Dr. Rutherford (Questions 2918 to 2935). This is all on the point of their belief. I am now going on to some fresh matter. Here is an experiment described by Dr. Rutherford at Questions 2918 to 2934, with his opinion and the opinion of Dr. Sibson: "A dog was starved for 18 hours; it was paralysed by curare through a cut in the throat, and artificial respiration was kept up. The abdomen was cut open and a tube inserted into the bile duct. The animal was kept in this condition eight hours, substances being frequently injected into the bowels. No anæsthetic was given because, in Dr. Rutherford's words, the "result of the experiment might be interfered with." He expresses his opinion of this operation that the pain was trivial.

13055. What was the date of it?—I do not know that any date was given. I have quoted the question in the last report. This opinion was endorsed by Dr. Sibson at Question 4760, because the animal was kept quiet by curare. Dr. Sibson's words are so remarkable that I give them: "There would be no struggling, the incisions would be made with great ease, the animal's mind would be withdrawn from what I would call the domain of attention, and when there is no attention there is no sensation, no sensitiveness, no pain." There are many more similar opinions in the Report of the last Royal Commission. At the present Commission the Inspector for Scotland (Question 750), expressed the opinion that pain varied as the intelligence, and when in Question 741 he was confronted with the evidence of the special senses, he made the curious and ambiguous statement that it is not every kind of dog that is good at smelling. He concluded that this evidence of special senses showed less susceptibility to pain. I give two more proofs of this wide-spread belief. In Mr. Keetley's "Index of Surgery," pages 180 and 181, second edition, is the operation for hare-lip in children. I quote, "Chloroform unnecessary. Secure his limbs by rolling him up tightly but firmly in a towel. If desired anæsthetic vapour may be pumped through a catheter." Then comes a description of the operation for which chloroform is unnecessary: "Begin by separating with the knife the two sides of the lip from the jaw subjacent. . . . Then pare the edges of the cleft. Remove enough. . . . In double hare-lip the intermaxillary nodule is pared"——

13056. I do not quite see how showing that certain operations were performed without anæsthetics, and were justified as being performed without anæsthetics, as I understand, before 1876, is material here, because we have now the Act of 1876, and what we have to inquire into is as to the desirability of amending it. Nobody has suggested to us that it should be recommended to dispense with anæsthetics?—That is not the point that I am trying to bring out at all. I am on one point only. That one point is that there is a wide-spread belief that pain varies as intelligence varies. That is the only point that at present I am trying to bring out.

13057. I think you have done that already by telling us the evidence of some eight or ten eminent medical men who all pronounce that opinion, and I think that opinion, no doubt, does prevail?—Then I will not pursue that subject further.

13058. That experiment is not on animals, it is on a child?—I know; but it has the same inference.

13059. (*Sir Mackenzie Chalmers.*) The inference being that the child feels as much as a grown-up being, although less intelligent?—Yes, but that this surgeon, at all events, did not believe it.

13060. Was he speaking solely with regard to children, or did he think the operation for hare-lip on anybody could be done without anæsthetics?—There is nothing in the book to reply to that question.

13061. (*Chairman.*) I really do not think you need labour that question about what the general opinion is, because, as I say, you have given already the evidence of a great many medical men thirty years ago;

* *Some of them gave reasons.—S. F. S.*

Mr. S. F. Smith, M.R.C.S.

29 Oct. 1907.

and I think that is the general view now. I am not speaking of that as a scientific matter myself, but as a general opinion?—Then I will pass over it. I wish to point out, however, that there are certain reasons why this belief is stronger in physiologists than it is in other people. This belief in physiologists is strengthened by two circumstances: First, there is the blunting of the sensibilities. I wish to give my own experience about that. The first time I saw a brutal experiment on an unanæsthetised animal I wished to leave the room—I was sickened by it. The next time I was less affected, and with every experiment I was still less affected, until eventually I was able to look on at the most terrible things without my emotions being moved in any way, and I had left only my intelligence to tell me that the animal was being tortured. And I submit that what occurred in my own case probably occurs to everybody who witnesses an experiment. Now English vivisectors go abroad. These experiments to which I am referring are continental experiments. That they go abroad I know from my own personal experience. Professor Starling told me that he spent some months at the Pasteur Institute; Professor Heger, of Brussels, told me that Sir Michael Foster spent some months there; and I have heard one or two other Englishmen say that they have vivisected abroad. But besides the blunting of the feelings from often witnessing experiments, there is another circumstance which I think deceives the experimenter. Animals which do not often use their vocal chords frequently do not give the manifestations of pain when under severe suffering. Of course, everybody knows that a horse, which does not use its vocal chord often, will endure severe flogging without making a sound, and similar things occur with rabbits. There is one other circumstance, too, which I think deceives the experimenters, and that is that I believe when an animal is under very severe torture it may be to a certain extent paralysed. Mantegazza, in his work on pain, described how he kept animals quiet when he was subjecting them to torture. He said there were two ways; one was by nailing them down by their feet, so that he seriously increased their pain with movement. Another means was by making the pain so severe that the animal was paralysed.

13062. When was this book written?—It was written a long time ago.

13063. Fifty years ago?—No, less than that. I could not tell you the exact date.

13064. What country did the gentleman who wrote it belong to?—Italy. The only point I am trying to bring out is that physiologists may be deceived. In experiments on rabbits, for instance, the severity of the pain may possibly paralyse the rabbit and it may not give the manifestations of pain, and therefore the experimenter may be deceived by that. That is the only point I am trying to bring out. That is all I have to say on that point.

13065. Then the next point I think you want to speak about is the evidence of pain inflicted by English experimenters?—Yes. As to direct evidence, we have nothing but what experimenters disclose. From an analysis of every experiment published in the "Journal of Physiology" from 1896 to 1900, inclusive, I have found that 71 per cent. were cutting experiments.

13066. What was the gross number of experiments in those five years?—I could not tell you. It was not very great. I have simply mentioned that I referred to every experiment in the "Journal of Physiology" for five years. This percentage refers to the nature of the experiments only, for in many cases these were repeated on numerous animals, the precise number of which is not stated. Of these cutting experiments, the animals were not killed at the end of the experiment in 31 per cent.

13067. Is that 31 per cent. of the whole or of the 71?—Of the 71 per cent.

13068. 31 per cent. of the 71?—Yes. The period for which they were kept alive afterwards varied from days to months. In the great majority of these cases I do not think there is much suffering, judging by the analogy of patients recovering from operations, but I think there is some. I am well qualified to state what may be felt after an operation from a personal experience of last year. After an operation for varicose veins one of the wounds, about an inch long, inflamed; there were some pent-up discharges, and the pain I suffered from them was very violent, I might call it almost unbearable. I was obliged to drug myself heavily with morphia. I also wish to point out that it has been said that these operations are done with precautions as to surgical cleanliness, but in an animal there may be very great difficulties in doing it. We have first to assume that the experimenter will always take the trouble to shave away the fur from the animal—that he would not be tempted to omit that. Also an animal will remove its dressings; it tears them off or rubs them off. It is very doubtful whether the wound could be kept surgically clean for that reason. There is another disclosure in the "Journal of Physiology," that in the cutting experiments curare was used in 10.3 per cent. That refers to those in the "Journal of Physiology" for the five years that I have mentioned.

13069. Can you say what particular class of experiment it was in which the curare was used?—I cannot. It is some years since I made this analysis.

13070. Can you say who it was?—I cannot. All I have left is my notes.

13071. (*Dr. Gaskell.*) Instead of saying 10.3 per cent. could you say the actual number of cases in which curare was used?—I cannot, but one can easily find it out by going to the "Journal of Physiology" for those years.

13072. (*Mr. Ram.*) Do you mean used without anæsthetics?—No.

13073. In addition to anæsthetics?—In addition to anæsthetics.

13074. (*Sir Mackenzie Chalmers.*) How many hundred cases altogether would be included. Would it be something like 200 or 300?—No, there would be a less number of experiments made. I cannot tell you the number of animals experimented on, but I do not think there were 100 in the whole five years.

13075. (*Dr. Gaskell.*) Have you a list of the names of the experimenters you are referring to?—No.

13076. (*Sir Mackenzie Chalmers.*) So that these percentages are calculated on a single 100 or less?—They are calculated on as many experiments as are mentioned in the "Journal of Physiology" for the five years.

13077. (*Mr. Ram.*) It may be less than 100 in the whole time?—Yes, I think so.

13078. (*Chairman.*) Have you any observation to make about the use of curare with anæsthetics?—Yes. I think I may pass over the physiological evidence that curare is not an anæsthetic; it is admitted.

13079. Yes?—But that is denied on the strength of one experiment which is in Mr. Paget's book of a servant girl who was poisoned by an arrow in her master's hall and became unconscious and did not feel pain. I think I might refer to that, because it is mentioned in Mr. Paget's book, and it is stated as evidence that curare is an anæsthetic. What I wish to point out regarding that case is, firstly, that there was no positive evidence that the poison was curare; secondly, there is no evidence that artificial respiration was either prompt or efficient. If it was not prompt or if it was not efficient, the asphyxia would account for the unconsciousness. The only authentic account of experiment on man is given by Liouville in the "Bulletin Général Therapeutique," 1865, page 404. An overdose had been given and artificial respiration had to be kept up until the patient recovered. Liouville adds: "The patient then related all he had felt, the preservation of his intellect, the annihilation of all power of movement, of which he gave a clear account, witnessing all that went on around him without being able to take any part in it, the fears expressed by some assistants present being by no means reassuring." Claude Bernard believed that curare greatly intensified the susceptibility to pain, and in dramatic language has stated that under it he inflicted the most atrocious suffering that the mind of man can conceive. That he was correct there is every reason to believe. The afferent impulse has no escape along the motor channels. Herbert Spencer has in

several places emphasised the fact that an impulse is lessened by escape through surrounding channels.

13080. (*Dr. Gaskell.*) Have you got the quotation of Claude Bernard, where he says that it intensifies pain?—I have not. It is such a well-known quotation and has been so often made that I did not think it would be questioned.

13081. It is the well-known quotation that you are referring to?—Yes.

(*Sir John McFadyean.*) Would it not be easier to find the references if it is so well-known?

(*Sir William Collins.*) At page 282 of Mr. Paget's book I think a reference is given.

13082. (*Chairman.*) That is hardly a quotation, and very likely does not give the whole of what Claude Bernard said. Mr. Paget wrote, "Claude Bernard believed that it did not in any way affect the sensory nerves, and he described in theatrical terms the animal as being unable to stir, but suffering horrible torture." That is an extract from the "Edinburgh Review," for July, 1899. It does not profess to give the exact words beyond that. Perhaps you will go on with your evidence?—I assert that every time curare is given to an animal there is danger of most terrible suffering being inflicted. I think it is certain that in the majority of cases, possibly in every case, the most appalling torture is perpetrated. My reasons are as follows. In giving anæsthetics to human beings, great care is necessary to give enough to produce unconsciousness and to avoid giving more than is required, so endangering life. There are certain indications as a guide. After a certain time absence of the corneal reflex shows that the anæsthetic may be stopped. Reappearance of the corneal reflex shows that more may be given. A slight movement of the patient (which, however, rarely happens with a skilled anæsthetist) shows that more must be given at once. With these guides in human patients, anæsthesia is safe and efficient, although the quantity of anæsthetic required by one patient may differ considerably from what may be required by another similar patient. In a curarised animal these guides are totally absent. Moreover, there are no means of knowing the idiosyncrasy of the animal as in human patients. My experience is that one dog requires more anæsthetic than another of the same size. Further, my experience is that to give just the right amount to a dog, that is, to give it enough for anæsthesia, without killing it, is more difficult than in human beings. My belief is, therefore, that if ever a curarised dog is properly anæsthetised it is by a lucky chance. I do not think there is the consolation of believing that in these curare cases with incomplete anæsthesia (I am presuming there is incomplete anæsthesia) the ether or chloroform given lessens the pain, as would be the case with morphia. I believe, that is to say, that when such anæsthetics as ether, chloroform, and gas are given, the dividing line between complete anæsthesia and complete consciousness to pain is a very sharp one. I have only two proofs to give of this. One is an operation on myself. I was given gas by an experienced anæsthetist. A hole was bored in my jaw, an operation of a few seconds. I felt an inability to move, and pain which appeared to me almost as bad as any pain could be. The second case was that of an intelligent man whom I anæsthetised. I had given him a considerable amount of A.C.E. (alcohol, chloroform, and ether). I believed his corneal reflex was absent. I told the surgeon he might begin. An incision was made. The patient struggled, and the surgeon had to wait. I questioned the patient afterwards, and he gave as his opinion that he could not have felt the pain more if he had had no anæsthetic at all.

13083. (*Sir Mackenzie Chalmers.*) What operation was that?—It was an operation for the removal of suppurating glands.

13084. (*Chairman.*) But in the case of a skilled anæsthetist, has he not sufficient guide, although the subject may be curarised, for seeing whether he is still under the influence of the anæsthetic?—The indications are all absent; there is no indication.

13085. That is what I wanted to know. Are they all absent?—They are all absent.

13086. There is nothing by which he can tell whether pain is felt?—Absolutely nothing.

13087. Is that the view of all anæsthetists?—Anæsthetists have nothing to do with curarised animals.

13088. But under the Act the anæsthetist is obliged to keep the animal under the anæsthetic to prevent pain; then it is his business to see that the animal is kept free from pain. The operators tell us that when curare is administered it is not with the view of enabling them to be careless about the anæsthetic, but with the view of obtaining absolute stillness and absence of reflex movements. Supposing that that is their object, namely, to keep the animal under anæsthetics while at the same time it is rendered absolutely still by curare, can they not discover whether the animal is fully under anæsthetics?—I have just pointed out that the only guides which they have which are present in an animal without curare are absent in the case of a curarised animal.

Mr. S. F. Smith, M.R.C.S. 29 Oct. 1907.

13089. Could the anæsthetist not tell by the eye or breathing, or anything else?—No.

13090. (*Sir John McFadyean.*) Are all these statements based on your own personal observation of attempts to anæsthetise animals that are curarised; have you ever seen this thing done?—Yes.

13091. (*Chairman.*) I am speaking with some doubt as to my memory, because it is some long time ago, but I think we have had skilled anæsthetists before us who have not come to the same opinion as yourself on that matter, and that is the reason why I asked you the question?—It seems to me obvious, because all you have got is the reflex of the cornea and the movement; that is all you have got in a human patient to guide you; in a human patient you have absolutely nothing else.

13092. However, that is clearly your opinion?—Yes.

13093. (*Sir William Collins.*) Does anyone maintain that the reflexes can be used as a guide in the case of a curarised animal?—No, nobody would maintain such a thing; it would be absurd.

13094. (*Chairman.*) I am not pledging myself as to what previous witnesses have said. I was rather under the impression that they had said that you could distinguish?—I am quite certain that no witness could have said that the corneal reflex is present.

13095. No; I used a very wide expression—whether there was anything that would give them the information?—Something was said about blood pressure, I believe, by one witness, but that is a point on which you want a great deal of corroboration of evidence.

13096. Or as to the quantity of anæsthetic that is being administered; would that be a guide?—I have already pointed out that the amount of anæsthetic that is required by one animal differs from the amount that is required by another animal of the same size. That has been my experience. If you only give enough to keep the animal alive you are in great danger of not having anæsthesia, and if you give sufficient to be more than certain that the animal is anæsthetised you will be in great danger of killing the animal.

13097. But that risk has to be run?—That risk has to be run; but it would depend upon the physiologists to say that they kill a great many animals when they are under curare.

13098. Is there anything more you wish to say upon that subject?—I think that is all I have to say about it.

13099. Then you wish to say something about the usefulness or not of vivisection?—I wish to state, first, that the reason why I am selecting certain claims is that when this book, "Experiments on Animals," was published by the Secretary of the Association for the Advancement of Medicine by Research, a number of medical men, including myself, were requested to inquire into the accuracy of the statements made therein. The work was split up, and what I am giving you now is what fell to my share. Firstly, on drugs. I am giving only a small part of the evidence which exists. I give certain facts first, and the inference to be drawn I shall place at the end. I may state that I am giving now only those drugs which begin with the letter A. I shall not go further than the letter A for the sake of brevity. I begin with alkalis. Referring to the experiments on the lower animals, Dr. Ringer says ("Therapeutics," page 127, fifth edition) that the results are contrary to experience of the action on the human body, and he indicates further that the animal experiments are in them-

Mr. S. F. Smith, M.R.C.S.

29 Oct. 1907.

selves contradictory. As regards acetate of ammonia, Stillé and Maisch ("National Dispensatory," page 836) point out that, given to healthy men, there are no decided symptoms; but that in rabbits there are fatal tetanic spasms and dissolution of the gastric mucous membrane. Amyl nitrite was discovered by the French chemist Balard in 1844. Later, Professor Guthrie, when distilling it, found it producing flushing of the face. The natural deduction is that the blood pressure would be lowered if the small arteries are dilated. Still later, animal experiments demonstrated that the blood pressure is lowered, but this was only corroboration of clinical observation. Apomorphia: The clinical effect of this drug on the heart is flatly contradicted by the animal experiments of Siebert and Moerz ("Bartholow's Materia Medica," page 459), and Wood (page 437) points out further discrepancy between human and physiological investigation. I pass over as of less importance, though interesting, the various contradictions between physiologists themselves as to the action of this drug. Arsenic: Drs. Ringer and Murrell ("Journal of Physiology," I., page 217) obtained on frogs different results from those of Dr. Sklarck, of Berlin. They believed the discrepancy to depend on the time of year. I prefer to leave it to a physiologist to answer the problem. If arsenic has a certain effect on frogs in May, what effect would it have on man in March? The absurdity of these experiments is as obvious as the unconscious humour of the experimenters. Atropine (obtained from belladonna): Its well-known action of dilating the pupil in man is absent in birds (Stillé). Birds and herbivorous animals eat belladonna with impunity. "This is one of the many examples," remarks Stillé and Maisch (page 276), "which show the danger of concluding from the lower animals to man in regard to the uses of medicines." I pass over the disputes among physiologists as to the effects of this drug upon animals. I observed this morning that I have left out the drug aconite, which begins with "A," about which similar observations could be made; but for the sake of brevity I state briefly that similar observations can be made concerning the following:—Benzoic acid, bronchitis, caffein, Calebar bean, camphor, carbonic acid gas, chloral, chrysophanic acid, citric acid, coculus indicus.

13100. When you say similar observations, what do you mean precisely—observations that they have not the same effect on man as on animals?—Yes, and that there have been diverse views among physiologists themselves as to the effects of these drugs.

13101. You say that you cannot argue from experiments on animals as to the effect on man in the case of these drugs?—No. Colocynth, conium, sulphate of copper, mercury, croton chloral hydrate, croton oil, coriaria, elaterium, muscarine, gamboge, glycerine, gelseminum, ground ivy (which is glechoma), guarana, hamamelis, hyoscyamis, ipecacuahana, jaborandi, lead, milk (when injected into veins), kalmia latifolia, musk, nitrate of silver, nitropentane, opium, phosphoric acid, podophyllin, rhus toxicodendron, prussic acid, quinine, ergot, sanguinaria, sarsaparilla, senega, soda, sow-bread (cyclamen), cantharides.

13102. Take prussic acid, for instance, is not that fatal both to animals and man?—Yes. I have not said that all the properties of drugs differ. I have only said that there are differences.

13103. What is the difference in the operation on man and animals in the case of prussic acid?—I have not got my notes here at present. I have only given you the particulars as to certain drugs. I simply mention that there is evidence regarding all the remaining drugs for the sake of brevity. If the Commission wished to listen to it all I should be pleased to have spoken for an hour on all these drugs.

13104. We do not want to hear about them all. I would suggest that you might have taken half a dozen of the greatest cases; but prussic acid is a poison that is so commonly known, and is known to be used so often for killing animals, that I thought I would ask you about it, as it caught my ear?—A drug may have common properties; for example, it may kill both; but it may also have some properties which are different. Prussic acid is not used as a medicine in man for killing; it is used for other purposes. You may have a drug which may have some properties in common and yet will have properties which differ.

13105. But you are not at the present moment, without your notes, able to say what the particular difference is in the operation of prussic acid on man and on animals?—No, I am not. Then there are squill, stramonium, strychnine, tartar emetic, thein, coriaria sarmentosa, tobacco, trimethylamine, veratria, and solanum dulcamara. An account of one drug not mentioned—namely, digitalis—is so important that it should be given. I do so because it is so often stated that the action of this drug was discovered by experiments on animals. "

13106. Some effects of it. I do not think that anybody has come to say that its use as a drug was not known independently of animal experimentation; but I think what has been contended is that it was discovered to have properties and effects on particular parts of the body which were not understood without experiments on animals?—Then, in that case, if the Commission is of that opinion, I will pass over that. The evidence is overwhelming that whether with old drugs or new, any conclusion from experiments on animals are absolutely untrustworthy, and would be dangerous if relied on. Mr. Berdoe, in his brochure on drugs, puts this clearly. He says: "Let us imagine that a quantity of a new drug, called opium, is being examined for the first time by a special committee. Let us assume that nobody knows anything about its properties except some vague travellers' tales. The physiologists proceed to investigate its action by a long series of experiments on animals. They give it to frogs, and they find that small doses throw them into tetanic spasms. They give 20 grains to a pigeon, which is none the worse for it; 30 grains are given to a rabbit with no effect. They are beginning to think the travellers' tales exaggerations, especially as they discover that ducks and chickens, like the pigeons and rabbits, are never the worse for its administration. They resolve now to try it on a human patient, and proceeding with extreme caution, as they think, they decide not to venture at first beyond the dose they gave to the pigeon—namely, 20 grains. The patient is a powerful navvy. He is promptly killed. If physiological medicine were of any value, surely the method followed by these investigators was right and cautious. Yet how fatal their method when reduced to practice."

13107. Are those physiological facts, that opium, for example, does not operate on pigeons and rabbits and frogs?—Yes. I wish to compare these facts with the statement of Sir Lauder Brunton, at Questions 6929 and 6930, before the present Commission, that animal experiments are absolutely necessary to learn the effects on man, and to learn, in Sir Lauder Brunton's own language, "a safe dose." I would draw attention also to his statements at Questions 6893 to 6897. They are that Gamgee's animal experiments led to the observation that the pulse tension in man is lowered by nitrite of amyl, and that this observation pointed to the treatment of angina pectoris by nitrite of amyl. This may be, but it was previously known that nitrite of amyl caused flushing. The deduction that the pulse tension would be found lessened is so glaringly obvious that if it was really overlooked great want of commonsense was shown. Gamgee's experiments should have been unnecessary. That is all I have to say about drugs.

13108. Then I think you desire to make some observations upon the claims in favour of the value of vivisection, or rather, I should say, of experiments on animals, because some are not cutting experiments, made by Mr. Stephen Paget in his work "Experiments on Animals"?—Yes; the action of drugs, of course, is part of that.

13109. And I think you take first the case of inoculation in typhoid fever?—In what I am going to say now I am only stating what I have published. Dr. Washbourn, Physician to Guy's Hospital, writes ("British Medical Journal," April 20th, 1901): "With regard to the value of inoculation, I am satisfied, from clinical observation, that it does not modify the disease. Mild, severe and fatal cases occur among the inoculated and non-inoculated, and, as far as one can judge, with the same frequency. Whether inoculation diminishes the incidence of enteric fever can only be determined by extensive statistics. From my own personal experience I should not think that the incidence is diminished." Dr. Melville, late civil surgeon to the Natal Field Force, writes ("British

Medical Journal," April 20th, 1901): "Inoculation.—Of my 295 cases, 30 were inoculated, the remaining 265 being unprotected in this manner. A few statistics comparing the results obtained in the two classes of cases are not devoid of interest. From the following table it will be observed that the uninoculated cases compare very favourably with the inoculated. The complications were more numerous, the duration of the fever longer, and the death rate higher in the inoculated." The table is as follows:—

Mr. S. F. Smith, M.R.C.S. 29 Oct. 1907.

	Complications.		Deaths.			
	Number of Cases.	Number of Cases.	Percentage.	Duration of Fever Days.	Number of Deaths.	Percentage.
Inoculated	30	12	40·00	29·57	2	6·67
Uninoculated	265	55	20·75	21·38	5	1·89
Total	295	67	22·71	22 21	7	2·38

That table shows that the percentage of deaths in inoculated cases was 6.67, and in the uninoculated, 1.89.

13110. (*Sir William Church.*) These figures which you are quoting are the experiences of those two gentlemen in South Africa?—Yes.

13111. They are not in any way a table of figures compiled to show the effect of inoculation or non-inoculation scientifically; they are merely a report of just such cases as happened to come before them during the South African War?—That is all. I have another table here which sets forth the complications met with in the uninoculated cases compared with those met with in the inoculated.

	Relapse.	Malaria.	Pneumonia.	Hæmorrhage.	Thrombosis.	Cerebral.	Peritonitis.	Erysipelas.	Total.
Inoculated	5	2	2	1	1	1	–	–	12
Uninoculated	18	3	9	16	4	1	3	1	55
Total	23	5	11	17	5	2	3	1	67

13112. (*Chairman.*) In Mr. Stephen Paget's book, in that part relating to typhoid fever, there are a good many tables of experience, where the inoculated have suffered less than the uninoculated, are there not?—Yes; all that I have said would show that there is a doubt about the matter.

13113. You have cited some in which the uninoculated came off better than the inoculated?—Yes.

13114. And he cites a good many others as well in which the reverse is the case?—Then, as I say, all that I have said simply shows that there is a doubt about the matter. I do not claim anything more than that. I next come to malaria. It is implied, though not definitely stated, by Mr. Paget that experiments on birds were necessary and essential in proving that mosquitoes convey malaria. Let us see how far he is justified in this. The following history is even admitted in Mr. Paget's book. It had long been suspected that mosquitoes caused the disease. The question was obscured by the circumstance that the common variety does not convey the poison, and that the kind responsible, the anopheles, does not buzz nor cause much irritation by its bite. In 1880, Laveran discovered the specific organism in the red blood corpuscles. In 1894 Manson suggested that this organism was removed from the blood by mosquitoes, and by a special variety. In 1895, Ross made observations on the organism found in mosquitoes after feeding them on malarial blood. The mosquito theory had now strong ground for credence. It remained to be proved that persons protected from mosquitoes in a malarial district would not get the disease, and that men bitten by the anopheles in a non-malarial district would get the disease. This was carried out and proved by a commission from the Tropical School of Medicine in 1900. Now, where was the necessity for experiments on birds. Could not a person of average intelligence have thought of the last experiment mentioned? It is true that Ross in 1898 showed that another variety of mosquito could convey an analogous disease to birds, and he also showed that this variety could not convey the malaria parasite to man. His experiment then was valueless, because it did not touch on malaria in man. That it was inconclusive was clearly the opinion of the Tropical School of Medicine, as evidenced by the fact that the final and convincing experiments on man were undertaken to settle the matter.

13115. What experiments on man are there that you refer to that were finally taken up?—One experiment was that they took a man who had had malaria previously, and therefore was very susceptible to it; they put him in a malarious district in Italy, where they kept him protected from mosquitoes, and they found that he did not get malaria. And the reverse experiment was that of I believe it was Dr. Manson's son, who allowed himself to be bitten in England, where there is no malaria, by malarial mosquitoes brought from a malarial district, and he contracted the disease.

13116. I understand that you do not doubt that mosquitoes do convey the disease?—I do not.

13117. But you say that experiments on animals were unnecessary to prove it?—They had nothing to

Mr. S. F. Smith M.R.C.S. 29 Oct. 1907.

do with the discovery, as is inferred, and as has been stated.

13118. (*Sir John McFadyean.*) Could you say whether that is Major Ronald Ross's own opinion as to the usefulness or uselessness of the researches which he had previously himself carried out on malaria in birds?—No, I have no information on the point.

13119. Would it affect your opinion if you knew that the discoverer himself did think so?—It would not affect my opinion unless he showed me the evidence. His mere opinion would not affect me.

13120. (*Chairman.*) Is that all you wish to say about malaria?—That is all.

13121. Then what is the next subject?—Suppuration and blood poisoning, I think, is the next. Mr. Paget writes: "The study of the micrococci has not only proved and made perfect the present methods of surgery; it has also discovered a serum for the cases of micrococcic infection. Take, for example, the disease called ulcerative endocarditis, the growth of micrococci on the valves of the heart, whence they are carried by the blood into different parts of the body. Several cases have lately been reported where recovery from this most hopeless disease has followed the use of the anti-streptococci serum. It has given excellent results in cases of puerperal fever and in cases of dissection wounds. Already, though it is a new thing, it has saved many lives, and is steadily gaining ground in practice." The truth of this statement can be estimated by comparing it with the following, which appeared in a leading article of the "Lancet" (November 18th, 1899): A valuable communication has been published ("American Journal of Obstetrics," September, 1899) by a committee appointed by the American Gynæcological Society to report upon and to investigate the value of the serum in the treatment of puerperal infection. A summary of the cases hitherto reported is given, showing that the results in 352 cases had been collected with a mortality of 20.74 per cent., and after a careful study of the literature of the subject the members of the committee formulate certain conclusions, amongst which they state that clinical observation has shown that the results obtained by employment of the serum leave a great deal to be desired, and apparently indicate that it has little, if any, effect upon the general course of streptococcic puerperal infection. The conclusions arrived at after careful consideration of the personal experiences of those forming the committee are even more emphatic, and include the following: "Experimental work has cast grave doubts upon the efficiency of anti-streptococcic serum in clinical work by showing that a serum which is obtained from a given streptococcus may protect an animal from that organism, but may be absolutely inefficient against another streptococcus, and that the number of sera which may be prepared is limited only by the number of varieties of streptococci which may exist." Again, they say: "The personal experience of your committee has shown that the mortality of streptococcus endometritis, if not interfered with, is something less than 5 per cent., and that such cases tend to recover if nature's work is not undone by too energetic local treatment." And, finally, the report ends with the words: "We find nothing in the clinical or experimental literature, or in our own experience, to indicate that its employment will materially improve the general results in the treatment of streptococcus puerperal infection." At the meeting of the British Medical Association held at Portsmouth this year, Dr. Herbert Spencer opened a discussion on the treatment of fever following delivery, with special reference to serum-therapy, in which the general opinion was expressed that although the whole question of serum treatment was too much in its infancy to justify any definite answer, the results hitherto obtained did not exhibit any material advantages over the methods generally adopted. In the "Lancet" of November 11th (pp. 1296, 1299), we published the reports of meetings of the Obstetrical Society of London, and of the Harveian Society of London, at which the subject was again discussed. At the first named Society, Dr. Herman read a paper on "Two cases in which life appeared to have been saved by anti-streptococci serum." The first was one in which a severe operation was followed by great prostration, from which the patient recovered, but the rally was followed by renewed prostration, such as in the speaker's former experience had ended in death. With anti-streptococcoc serum the symptoms quickly improved, and the patient got well. The second case was a puerperal one. Dr. Herman thought, however, that judgment as to the therapeutic value of the serum was difficult, because sufficient knowledge of the effects of the streptococcus was not yet forthcoming. The succeeding speakers all spoke in a doubtful tone as regards the therapeutic value of the serum. At the meeting of the Harveian Society, Dr. J. W. Washbourn stated that as the results of his experience, the serum was of extreme value in certain cases, but that it was valueless in other cases apparently identical. That is to say, there is a great deal of opinion that serum treatment in suppuration is useless.

13122. Did he mean by that, that in some cases the serum supplied had an effect and in others the serum had no effect, or that in some cases the same serum would have a different effect on different patients?—I do not know that that question is answered. I do not know that the report gives that information.

13123. In all these experiments on serum, so far as I understand, a great deal depends upon the purity and strength of the serum?—There is so much doubt about the whole matter that it must be a matter of opinion.

13124. (*Sir John McFadyean.*) Dr. Washbourn is dead, is he not?—I do not know. I am quoting now.

13125. (*Dr. Gaskell.*) Where is this statement in Mr. Paget's book; I cannot find it?—I think my edition of Mr. Paget's book is the first edition.

13126. It does not occur in the edition that I have; I cannot find it?—I have not seen any other edition but the first, I think.

13127. He does not seem to lay that same stress on it in the later edition which he did in what you quoted; at least, I cannot find it here?—I have seen nothing but the first edition of Mr. Paget's book. I did not know that it was altered.

13128. (*Chairman.*) I think you have read us what Dr. Washbourn said?—Yes.

13129. And you have read also what Dr. Herman said?—Yes.

13130. Then, I think, the next case you deal with is myxœdema?—Yes. It has been found that after removal of the thyroid gland—sometimes performed for hypertrophy—myxœdema follows. Now, since this disease does not come on when the patient possesses a thyroid gland, either healthy or enlarged, it is neither difficult nor brilliant to conclude that this gland produces something which prevents myxœdema. If we lost our watch and found we could not tell the time, it would not require much brain power to see that this was due to the absence of the watch. To buy another watch might occur to an unscientific person, without experiments on animals. Similarly, it is simple to see that to administer to a patient something from the loss of which he is suffering would probably give relief. And, as a fact, it is found that patients with myxœdema are benefited by taking thyroid gland from the lower animals, swallowed in tabloids. What is there wonderful in this? It is only common-sense applied. Mr. Stephen Paget tacitly implies that there is something difficult in this simple reasoning, and that it was necessary to ascertain, by removing the thyroid gland from monkeys, whether excision of a healthy gland would cause myxœdema. It might have been interesting; but why necessary? With a healthy gland—no myxœdema. With a hypertrophied gland—no myxœdema. With no gland at all—myxœdema. One who could not see the plain inference from this must be a person of diminished intelligence. If there had been any evidence that in goitre the function of the gland is destroyed by the hypertrophy, then something, though not much, might be said for the experiment on monkeys. But there was no such evidence. Goitres are only hypertrophy of one of the normal structures of the gland—the fibrous tissue, the vascular tissue, etc. There was no reason at all for assuming the function to be entirely lost. Hypertrophied muscle, or bone, or heart, does not cease to act. On the contrary, the fact that goitres usually cause no symptoms, but pressure, and that severe symptoms only come on when the gland is removed proves that the function is not lost. This is so plain that he who runs may read.

13131. Do I rightly understand your view to be that the cause of myxœdema was thoroughly and completely understood before any experiments were made on

animals?—Yes. That is all I have to say about myxœdema.

13132. Then we come to the anti-tetanus serum?—Mr. Paget remarks of anti-tetanus serum: "It is only ten years since Kitasato first obtained pure cultures of Nicolaier's bacillus; yet here is a good record already of lives saved or protected. Dr. Whitla, in his "Dictionary of Treatment," says: "Notwithstanding all the reported successes, there is little evidence of the value of injections of the anti-tetanic serum. Great numbers of cures are recorded in those cases where the period of incubation was prolonged much beyond the average noticed in severe cases, and it must be remembered that these are the class of cases where a spontaneous cure is the most likely to occur, and many reported successes would doubtless have been safe without the serum." Messrs. Rose and Carless state in their "Manual of Surgery": "At present the results of this treatment have proved disappointing, since few cases of acute tetanus have been cured by it, and the effect even in the more chronic cases is not at all certain." The "Lancet," May 20th, 1903, remarks: "Anti-tetanic serum has hitherto not fulfilled the expectations which were hoped from its use. . . . It is very uncertain."

13133. Do you express any opinion as to whether serum has been useful in any cases?—All I have been able to find out is that it is not of use. Are you speaking of serum generally or of anti-tetanus serum?

13134. I am speaking of the anti-tetanus serum?—I have no evidence except this evidence which I have already given.

13135. There have been a good many experiments, have there not, with it?—Yes, there must have been a great many.

13136. Then as to diphtheria, we have heard a good deal of evidence about the success of the anti-toxin in diphtheria?—May I take hydrophobia first?

13137. If you please?—There are certain minor considerations. Those are, that Pasteur has published misleading accounts of his experiments, that he equivocated and was compelled to admit it, that some features of the treatment are empirical guesswork and without foundation. I pass these over to come to the crucial point—the statistical evidence. This evidence is of two kinds. First, the gross mortality in France of French people from hydrophobia before and after Pasteur's treatment. Second, the case mortality. Please note that all the figures refer to French people. At the Pasteur Institute the figures of the foreigners were kept distinct and apart. My authorities for the following statements are the annals of the Pasteur Institute, Dr. Dolan's book on "Hydrophobia," "Etudes sur la Rage" by Dr. Luteaud, editor of the "Journal de Médecine," and Dr. Auguste Marie's work on "La Rage." I take the gross mortality first. There are three sets of figures: those of the Paris hospitals, those of the Department of the Seine, those of all France. Dr. Luteaud has shown that at the Paris hospitals the mortality before and after 1885 was the same. His figures give the names of the patients at each hospital for each year.

13138. (*Sir John McFadyean.*) Might I have a point made perfectly plain? What does this gross mortality mean—mortality among untreated persons?—The mortality among persons treated by Pasteur and not treated by him; but they refer to French people only, not foreigners.

13139. That is not the question. Are the bulk of them treated or untreated?—Presently I shall show you that about half were treated.

13140. You cannot discriminate between those who were treated and those who were not?—Are you referring now to what proportion these people were?

13141. I am referring to what you call the gross mortality?—By the gross mortality I mean the total number of deaths from hydrophobia in France of French people in a year.

13242. But what I meant was, that there did not seem to be any purpose in giving us the mortality of untreated people in judging of the effect of treatment, and I wondered whether you could leave out of account those not treated?—That would be no use. All I am trying to say now is that the total number of deaths did not go down after the Pasteurian treatment began

(*Chairman.*) What we would particularly like to know is, where the rabies anti-toxin has been tried, in how many cases it has been successful.

(*Sir William Collins.*) I also think it is important to know what was the gross mortality distributed among those treated and those not treated.

13143. (*Sir Mackenzie Chalmers.*) What was the gross mortality?—I am coming to that.

13144. In that last statement that you read of Dr. Luteaud, does he state whether they were treated or untreated cases?—Some treated and some untreated.

13145. (*Sir John McFadyean.*) What is the date of this? You say after 1885?—Yes.

13146. What is the date of the report you are quoting now?—I think it is for the following year.

13147. 1886?—Yes.

13148. (*Sir William Collins.*) Can you give the total deaths from hydrophobia in France during a series of years, either per million of the population or otherwise?—I am coming to that in a moment. Professor Michel Peter, another eminent Parisian clinician, showed in the "Journal de Médecine de Paris," July 5th, 1890, that if the figures for the Department of the Seine be compared for four years before and after 1885, they are 38 in one case and 37 in the other. That is to say, there were 38 for four years before 1885 and there were 37 afterwards.

13149. (*Chairman.*) Is 1885 fixed by you as the date when Pasteur began his treatment?—Yes.

13150. (*Sir Mackenzie Chalmers.*) How many years afterwards does this include?—Four years before and four years after.

13151. (*Sir William Collins.*) Is that a rate or total number?—It is simply the total mortality. There is nothing about case mortality at present.

13152. It is the total number of deaths?—Yes, the total number of deaths in the Department of the Seine of French people for four years before and four years after the introduction of Pasteur's treatment.

13153. (*Sir John McFadyean.*) Have you any statistics along with that as to the incidence of rabies among dogs in those years?—Yes, I am coming to that. If, however, the figures are taken for five years before and after 1885 the figures are 41 to 59. That is to say, that whereas in the five years previous 41 died, in the five subsequent years 59 died.

13154. (*Sir William Collins.*) Does that include the figures for Paris?—I do not know. It is simply given as the figures for the Department of the Seine.

(*Witness.*) Thirdly, the gross mortality for all France. The average annual mortality for a great many years, as given by the French Government, was 30. Dr. Auguste Marie gives also 30. Tardieu, in 1863, gave 25 as the average annual mortality. That these figures are correct is supported by the statistics of other countries, which show nearly the same mortality in proportion to population. The figures shown by the Dutch Government showed an average of less than 2, Belgium had an average of 2.6, Sweden, 4.2. In England, from 1864 to 1883 the average was 35. All these figures refer to pre-Pasteurian years. Pasteur's treatment began in July, 1885. In 1886 the deaths were of French people, 36, an increase above average, although Pasteur was treating immense numbers of patients. According to Dr. Dolan and Dr. Luteaud, the gross mortality continued higher than 30 in succeeding years. From the gross mortality there is an absence of any evidence that Pasteur has ever cured a patient of hydrophobia, and no such evidence has ever been claimed. If anything at all is proved, it is that the treatment killed. There is next the case mortality. I am coming now to the question that was asked about the number of dog bites, that is to say, the number of deaths in each 100 people bitten by dogs mad, or supposed to be mad. Pasteur's case mortality was about 1 per cent. Compared with the case mortality of any text book or any authority, this is an immense improvement. But the question necessary to face is this: Is even a single text book or authority right? There are two answers to the question. 1. There is strong presumptive evidence that every one is wrong. 2. There is direct and positive proof that every one is wrong, and that the real mortality from hydrophobia, without treatment, is the same as Pasteur obtained. I take the presump-

Mr. S. F. Smith, M.R.C.S.
29 Oct. 1907.

tive evidence first, that is to say, the presumptive evidence that all the text books and authorities are wrong about the case mortality of hydrophobia. Suppose that the age of some one named John Smith were in question. Suppose one authority gave his age as 5 and another authority as 75, and that every other authority gave a different age, not more than one could be right. If there were 20 authorities, 19 must be wrong. And if 19 are mistaken it is probable that the twentieth would be mistaken also. Here are some authorities on the percentage mortality of hydrophobia: Brouardel gives 31 per cent, below the age of 20, and 62 per cent. above it. Tardieu, Bouley and the Comité d'Hygiène in France give a mortality of 30 per cent. for cauterised wounds and 80 per cent. for non-cauterised wounds. Bouley gives another estimate of 47 per cent. Faber (Wurtemburg), gives 20 per cent. Werner states 22 per cent.; Poland ("Holme's System of Surgery"), says it is 25 per cent.; Gamgee ("Reynold's System of Medicine"), says it varies from 5 to 50 per cent.; Gowers ("Quain's Dictionary of Medicine"), gives a mortality of from 50 to 75 per cent. Pasteur himself believed (or at least said he believed), it was 20 per cent. Mr. Paget, with unconscious humour, remarks, "What was the risk of a bite from a rabid animal in the days before 1885? It is a matter of guess work." The reasons for all this diversity of opinion are easy to see. There is the great rarity of the disease. Perhaps not one medical man in a hundred ever sees a case. This factor alone would prevent reliable statistics. There was the custom of killing the dog to prevent its biting more people. There is the fact that there are about half-a-dozen diseases simulating rabies. It is easy to see what has happened. A dog bites a number of people. Nobody dies. Natural conclusions, the dog was not mad. The figures are excluded from statistics. The text book figures are therefore worthless from their mutual contradiction, and from the fallacies which must have come in. I come now to the positive proof.

13155. (*Chairman.*) You are proposing to deal with the figures in the text books?—Yes. I shall show directly that the real mortality in the untreated people is about 1 per cent. Further, I shall show that even a belief in the lowest figure ever given—that is, in the text books—namely, 5 per cent., is a hopeless absurdity. The figures which condemn Pasteur's pretensions come from the Pasteur Institute. In 1886, the first whole year of Pasteur's treatment, 36 French people died of hydrophobia; 19 were treated by Pasteur, 17 were not. It is with these 17 who stayed away we are now concerned.

13156. Are these figures taken from some French statistics?—They are French statistics taken from Dr. Luteaud's work on "Etudes sur la Rage," and Dr. Dolan's book on Hydrophobia. The average total mortality in France was 30, as we have seen. I am going to give certain figures with certain deductions, and these are somewhat difficult to follow. I consider them very important, and I will give them slowly. Seventeen is rather more than the half of 30. We may therefore presume that rather more than half the dog-bitten people stayed away from the Pasteur Institute. Let us assume that at least half stayed away, which is conceding Pasteur a slight advantage; that is to say, apparently, by these figures more than half stayed away; but we will give Pasteur the advantage and concede that one-half stayed away. If half stayed away the other half went.

13157. (*Sir William Church.*) This is only supposition. You do not give us any figures?—I do give the figures.

13158. (*Chairman.*) What you told us was that 36 was the number who died in that year?—Thirty-six French people died in the year 1886.

13159. Then you must take your 19 who died as against the 36, and not against the 30?—The assumption is that Pasteur's treatment modified in some way the number of deaths. I am leaving that for a moment. I am taking 17 who died without going. I am only trying to show at present how many dog-bitten people stayed away from the Pasteur Institute. Do you follow?

13160. I cannot see, if you deal with the figures of 1886, how you can diminish those who actually stayed away to 30. You say that 19 were treated and 17 were not. You must deal with those figures?—The 17 people, then, who died did not go to the Pasteur Institute. Is that admitted?

13161. That I understand to be what you say?—Therefore, if 17 did not go, if 30 was the average, the presumption is that more than half the people untreated by Pasteur, bitten by dogs, mad or supposed to be mad, did not go.

13162. That I do not follow?—I think it is perfectly clear. It is a question of whether you understand me?

13163. No, it is my understanding that is lacking?—It is no good my going on unless that point is clear.

13164. (*Sir John McFadyean.*) Do you mean that a mortality of 30 would mean probably somewhere about 100 or 200 people bitten annually?—I am not talking about that.

13165. Then I am another who is unable to follow you?—Then let me begin again.

13166. (*Chairman.*) I think we understand, so far as you have gone, what you have said, but I was saying that you introduced the figure 30 as the average after having introduced the actual number of deaths and the actual number treated?—I have given a considerable number before that—30 was the average.

13167. I know that. Now, you introduce that 30 which does not seem to me to have anything to do with the question as to a year in which there were undoubtedly 36?—It seems to me it has very much to do with it. Seventeen French people in 1886 died in France who had not been to the Pasteur Institute. Supposing 34 people were the average, we might assume, then, that half the dog-bitten people stayed away. Is that clear?

13168. To my mind it is not of the slightest importance whether half or one more or one less than half stayed away. Say about half?—About half. Is that clear?

13169. You cannot either prove or disprove the usefulness of antitoxins by such distinctions as that?—These are the best figures we have got.

13170. Yes, I understand that?—Is it admitted that about half the dog-bitten people in France stayed away?

13171. (*Sir John McFadyean.*) That is what I want you to explain—how you know the number of people who stayed away from the number who died of hydrophobia without treatment?—This surely shows us.

13172. I tried to help you out a minute ago by suggesting that you might have estimated the number of people bitten annually from the number of people who died from hydrophobia, but you did not take it?—No, not at present.

13173. Then I do not know yet how you arrive at it?—I have not shown you yet. But what I want you to admit at present is that if 17 people in 1886 died of hydrophobia without going to Pasteur, it is probable that at least half the dog-bitten people stayed away.

13174. But we cannot see that?—Because the average is 30.

13175. (*Chairman.*) I think you had better present your argument without asking us to admit it?—Then I will state it, and I think at your leisure you will admit it. Thirty was the annual average; 17 is rather more than the half of 30. We may therefore presume that rather more than half the dog-bitten people stayed away from the Pasteur Institute. Let us assume that at least half stayed away, which is conceding Pasteur a slight advantage. If half stayed away the other half went. I think that will be admitted.

13176. (*Mr. Ram.*) The other half may be supposed to have gone, you mean?—Assuming that half stayed away, you must admit that the other half went. We know the number who went. On arriving they were counted; they were, in round numbers, 1,500.* I take these figures in another aspect. If half the dog-bitten people were 1,500, all the dog-bitten people were 3,000.

* *1,500 is a round number only. The figures in 1887 were 1,531 and in 1888, 1,404. My recollection is that in 1886 the figure was a little less.—S. F. S.*

13177. (*Chairman.*) When you say that half went, the other half of the 36 or the 30 went; but as to the other 1,460, I do not see why you say that they went to the Pasteur Institute?—They were counted.

13178. (*Mr. Ram.*) You know the number that went to Pasteur?—Yes.

13179. What indication does that give you of the number that did not go?—That can be arrived at by observing the number of deaths of untreated people, and comparing them with the previous average annual deaths.

13180. (*Chairman.*) Besides, the 30 are the number of people who died in France?—Yes, annually.

13181. But how many of these 1,500 people were foreigners who came to be treated by Pasteur?—The figures are kept distinct in the Annals of the Pasteur Institute.

13182. They are beyond the 1,500?—Yes, with foreigners there were about 2,000. I disregarded foreigners altogether. If half the dog-bitten people were 1,500, all the dog-bitten people were 3,000. Now, for the first time in history we have some reliable figures on a large scale as to the number of dog-bitten people in a country in a year. Now, compare the annual mortality in France—viz., 30—with the number of people—viz., 3,000—bitten by dogs mad and supposed to be mad; 30 to 3,000 gives 1 per cent. This is the real mortality of hydrophobia in dog-bitten people. If we accept any other percentage figure of the text books we are reduced to absurdity. If we accept even 10 per cent., then 10 per cent. of 3,000 is 300. To believe that 300 would have died in a year would be to assume that from some cause the mortality suddenly jumped from 30 to 300. If we accept the lowest figure ever given, 5 per cent. mortality, we are in inextricable difficulties with a gross mortality of 150. The pretensions of Pasteur's treatment rest upon statistics and by statistics they are condemned.

13183. All the 36 who died undoubtedly had hydrophobia?—Yes.

13184. Why do you reason from that that the 1,500 who went to Pasteur must undoubtedly represent half of the people who were bitten?—Bitten by dogs mad or supposed to be mad.

13185. I do not quite follow why it should be so?—It seemed to me so clear that it makes it appear to me as if you had not understood me.

13186. I desired to bring it to your mind that I did not understand you?—I think the figures undoubtedly are that in the first year, 1886, 17 people who did not go to Pasteur died of hydrophobia—that is a certainty. It is a certainty that the average annual mortality in France was 30.

13187. (*Sir Mackenzie Chalmers.*) In that year or in other years?—Extending over a number of years. I said that was an average. Then, as 17 is very nearly the half of 30, we may assume that half the people stayed away from the Pasteur Institute.

(*Mr. Ram.*) I cannot follow that; that is where my difficulty comes in.

13188. (*Sir Mackenzie Chalmers.*) There is a *non sequitor* there?—It is so absolutely clear—there is no *non sequitor*. Let us assume that in each year 30 people always died, never more and never less. Let us assume that in 1886 15 people died without going to Pasteur, surely that would show that half the dog-bitten people did not go to Pasteur.

13189. (*Mr. Ram.*) Why are we to assume that?—To make it clear.

13190. (*Chairman.*) It is not a question of assuming a thing to make it clear. The point is to make it clear that you have a right to assume it?—It seems to me already so clear.

13191. (*Sir William Collins.*) Are you suggesting that the ratio of cases treated and untreated must be regarded as the same as the ratio of deaths of treated and untreated?—No, I am not assuming that. That does occur, but I am not assuming it.

13192. (*Sir John McFadyean.*) Are you forming any estimate, then, as to the number of people annually bitten in France from the fact that 30 was the average mortality?—Not directly, but indirectly.

13193. Indirectly, how?—Indirectly, in this way: 30 people died annually. In the year 1886, 17 people, about half of the 30, died without being treated at the Pasteur Institute. Surely it follows—it is no *non sequitor*—that half the people stayed away from the Pasteur Institute. It seems to me to be absolutely clear.

Mr. S. F. Smith, M.R.C.S.
29 Oct. 1907.

13194. (*Mr. Ram.*) Do you know how many went to Pasteur in that year?—Yes.

13195. How many?—Something over 1,500 in the year 1886.*

13196. Then do you mean that because 19 went——?—No, 19 did not go.

13197. How many went?—1,500.

13198. And how many died altogether?—In the whole of France 36.

13199. Of those you say that 17 were not treated at all?—Yes.

13200. Is your deduction that the rest of the number between 17 and 36 did go to Pasteur and did die?—Yes.

13201. That is your deduction?—No, it is not a deduction, it is a fact given by Pasteur.

13202. (*Sir Mackenzie Chalmers.*) He got 19 deaths out of 1,500 cases?—He got 19 deaths out of 1,500 cases.

13203. You want us to assume that there were another 1,500 cases with a similar number of deaths that were not treated?—With 17 deaths that were not treated.

13204. (*Sir John McFadyean.*) Might I ask you a question with regard to what you call the average mortality, which you said was 30? Can you tell us whether it fluctuated very much?—Yes.

13205. What were the extremes?—I believe there were in one year as many as 47. I think that was the extreme year.†

13206. Perhaps you could tell us if you have the statistics handy?—I have them all here.

13207. (*Mr. Ram.*) What you want to put comes to this, does it not? That out of the total number of 1,500 of those that went to Pasteur he got no better percentage of deaths, rather worse, than out of the number of 1,500 who did not go to him, and who died?—No, not quite like that. I have not worked it out; that is not the point I have been trying to make.

13208. (*Chairman.*) You have been giving these figures with the object of showing that the number of deaths in the natural course of events without Pasteur interfering is 17?—Yes, that is my object.

13209. It does not, to my mind, prove it. I see what you mean by it, but I am not at all satisfied that the same ratio exists between those who go there and die and those who go there and survive?—I would leave out of question at first all those thousands who went to Pasteur for the time being altogether, and I will take the 17 who died without going to Pasteur, and as 17 is about half the average, we may assume, certainly, that half stayed away.

13210. I think you have put your argument. I quite see what your argument is; but all I can say is that, from some deficiency in my mind very likely, it does not convey to me proof that 1 per cent. of the people died?—It seems to me that the proof is absolute so far as any proof of that kind goes; that these are the best figures we have on a large scale of the real mortality of hydrophobia.

13211. When you say that it is absolute, that is where I differ from you. It may be something to help you in forming a rough judgment, that is all I can say?—I think Sir John McFadyean asked for the figures.

13212. (*Sir John McFadyean.*) But do not let me interrupt your argument, it can stand over quite well; it was merely because it seemed to affect the argument whether they fluctuated?—That is all I have to say. My point was to prove from these figures that the real mortality from hydrophobia is 1 per cent., and that Pasteur, in comparing his mortality with the figures in the text books, was comparing his mortality with a fiction—with a figment. I may say that when

* *Less than 1,500.—S. F. S.*
† *The highest was 66 in 1864.—S. F. S.*

Mr. S. F. Smith, M.R.C.S.
29 Oct. 1907.

Pasteur's treatment was first introduced there was a great deal of scepticism among Paris physicians as to the value of it, and both his figures and the circumstances of the case were subjected to very close examination. I give what Dr. Luteaud says about the evidence.

13213. (*Sir Mackenzie Chalmers.*) What is the date of that?—Dr. Luteaud's book was published in 1891. This is merely a summary of what is contained there; it is briefer than in the book. Hydrophobia shows itself under two forms—the convulsive form or the paralytic form. All authorities agree that the latter variety is extremely rare. In the year 1886 twenty-two of Pasteur's patients died of hydrophobia. I said 19 a moment ago. There was a dispute, that is why I say 22 here. Seven of these, practically one-third, died of the paralytic form. This is significant, because the virus which Pasteur injected on his patients, the "fixed virus" of the laboratory, invariably produces paralytic rabies in the rabbit. All authorities are likewise agreed that a common symptom at the onset of the malady is pricking at the place of the bite. Now, in many of Pasteur's fatal cases this sign appeared not at the bite, but at the point of inoculation. This occurred in the case of Bernard Sodini, who was treated on October 21st, 1886, and died November 24th. Such was the case also with Léopold Née, of Arras, who was treated November 17th, 1886, and died December 17th. Many more cases might be quoted. But all this is not absolutely conclusive, it may be objected. It is only presumptive. True. But what shall we say of the following? In July, 1887, Arthur Stoboi was bitten by a dog at Lubline, in Russia. On the chance that the dog might be mad he was sent to the Pasteur Institute at Warsaw, where he was treated by Dr. Boniville till August 11th. He died of hydrophobia on November 11th. The disease was preceded by pains at the seat of inoculation. The dog remained healthy, and lived for years afterwards. The same test—the survival of the dog—proved that in the cases of Née, of Arras, De Moens, of Antwerp, and of others, Pasteur was the cause of death and not the dog.

13214. (*Chairman.*) Is that all you propose to say about rabies?—Yes.

13215. Have you had any experience of treating rabies yourself?—No.

13216. What you have given us is from the books and opinions and statistics of others?—Yes.

13217. Do you think there is any antecedent improbability in an anti-toxin being discovered that would cure rabies?—It seems to me that that question is one of the widest questions that it is possible to put. It seems to open up everything.

13218. (*Mr. Ram.*) And what is the answer to it?—The question is too wide.

13219. (*Chairman.*) You mean, in fact, that you have never considered the subject sufficiently to say whether you do or do not see an antecedent improbability in treating rabies successfully by an anti-toxin?—The question seems so wide that I am not quite sure whether it has some less wide meaning than it appears to me to have.

13220. I assure you that I put the question in perfect good faith?—I have no doubt of that, but it seems so wide.

13221. You are not prepared to give an answer to it?—I am not.

13222. Very well. Supposing that in 1886, 24 out of Pasteur's 36 patients had died instead of 19 that would alter your figure altogether. It would not be at all an unlikely thing, would it, that out of 36 patients there might be a considerable variety between those who were cured and those who were not cured?—Do you say a considerable variety?

13223. A considerable variance?—A variance in what way?

13224. That in one year two-thirds of Pasteur's patients might die and in another year only half?—No two-thirds never died; only 1 per cent. died.

13225. But I mean that two-thirds of those who did die might be Pasteur's patients, and at another time only half?—Perhaps some variation of that kind might have occurred.

13226. Then your average of 1 per cent. would vary enormously in that case, would it not?—Not enormously, but it would vary to some extent.*

13227. A good many hundreds you would knock off or put on?—It is a question of mental arithmetic which is rather difficult for me.

13228. You speak of it as being such an absolute certainty that because they were 17 out of 30, or 19 out of 36, or whatever it was, of Pasteur's patients who died, there must exist exactly the same proportion always, and that that proves positively that 1 per cent. is the true average?—But it is just as likely that the figures might have fluctuated one way as the other.

13229. You do not know; you cannot take a single year and say it is just as likely the same thing might happen every year. However, I will not argue it further. I point out just why your reasoning does not seem to me satisfactory as to the 1 per cent. You passed over something that you wished to refer to, diphtheria?—The value of the anti-toxin for diphtheria has been disputed by a host of writers, especially continental and American. England is the exception; there has been little scepticism in England compared with what there has been in other countries. The objections to belief in anti-toxin fall into two classes; first, the theory underlying the treatment is not proved (we may call this speculative objections); second, the mortality statistics are a barrier (we may call this positive objections). Taking the speculative objections first, a patient attacked by such diseases as scarlatina, small pox or diphtheria, usually recovers. In some way Nature throws off the disease. So far we are merely stating facts. But when we try to explain how the "throwing off" is effected, we embark on speculation. We may assume, first, that the cells of which the body is composed become resistant to the disease; second, that the body manufactures an anti-toxin (anti-poison), which neutralises the toxin (poison) of the disease. These theories have two points in common—(a) They furnish us with a comfortable and seductive working hypothesis; (b) they may be true, but they lack proof. It is with the second theory that we are concerned, for on it is based the serum treatment of diphtheria. This therapeutic measure was adopted on the following grounds: In 1883 Klebs discovered a bacillus believed to be specific to diphtheria. (By "specific" is meant that it causes the disease.) From further research by Löffler it has been called the Klebs-Löffler bacillus. The reasons for believing it to be the cause of diphtheria are the following: (1) It is found in a large percentage of diphtheria cases; (2) Injected into the lower animals it kills; (3) It causes on mucous membranes an appearance resembling diphtheria. Whether this evidence is convincing we must subsequently consider. The anti-toxin treatment arose as follows: It is stated as a well-established fact that if an animal be inured to small doses of the bacterium it becomes immune to large doses. It is stated also that if the blood serum from an immunised animal be injected into a fresh animal, the latter is protected against an otherwise fatal dose of bacilli. Assuming that the Klebs-Löffler bacillus is the cause of diphtheria, we might expect the blood serum of immunised animals to protect man to some extent against the disease. The weak points in this speculation are the following: (1) There are reasons for believing that the Klebs-Löffler bacillus is not the cause of the disease. If this is true, the treatment cannot correspond with the theory. (2) Even with belief in the specificity of the bacillus, it would be necessary to prove that the results observed in animals occur also in man. The reasons for disbelieving that the Klebs-Löffler bacillus is the cause of diphtheria are as follows: Koch made the following demands before admitting the specificity of a micro-organism: (1) It must always be found in the disease it is supposed to produce; (2) It must not be found in healthy persons or in other diseases; (3) A pure cultivation injected into an animal must cause the disease and be found again in that animal. As the third test can be disposed of briefly, we may refer to it first. The most that can be said for the view that the bacillus causes diphtheria in animals is that (a) It kills; (b) It causes a white

* *Such a supposition would show a natural mortality of 1½ per cent., a slight variation only.—S. F. S.*

appearance on mucous membranes. But these two circumstances are not convincing. Many poisons kill. Many agents, including chemicals, render mucous membranes white. Hencke, after a series of experiments, arrived at the following declaration, in which not even a hope is expressed that the identity of human diphtheria and the artificial disease in animals is established. He says: "Diphtheria of guinea-pigs has, as is well known, not the least resemblance to human diphtheria, as the most enthusiastic adherents of the Klebs-Löffler bacillus have to admit." By Koch's third test, therefore, the claim of the bacillus to specificity breaks down. Here is a convenient place to notice an illogical position, in which the bacteriologists have placed themselves. They deny the value of naked eye appearances for diagnosis of diphtheria in man. They rely on naked eye appearances for diagnosis of diphtheria in animals. They beg the whole question. Koch's first test is that the bacterium must always be found in the disease. Löffler himself regarded the coincidence of clinical and bacteriological diagnosis as doubtful. This has been affirmed by others. He himself failed to find the bacillus in 25 per cent. of diphtheria cases. Hennig believed the bacterium to be absent in more than 25 per cent. The first test, therefore, fails. Bacteriologists have attempted to avoid this objection by denying that any cases are diphtheria unless the bacillus is found. This, again, begs the whole question. We have the position humorously described by Hanseman: "The Klebs- Löffler bacillus is to be found in all cases of diphtheria, provided we select only those cases in which it is present." Koch's second test is that the bacillus must not be found in health and other diseases. Ritter has found the bacterium (fully virulent to animals) in the mouths of healthy children (127 cases), of nurses of diphtheria patients, and in their noses and throats up to four weeks after disappearance of the disease. It is often found even months afterwards. Uthoff and Fränkel found it in the conjunctiva. Meyer noticed that of some children who were exposed to the same source of infection, one caught a harmless sore throat, another a malignant diphtheria, but both with the bacillus equally virulent to animals. The presence of the bacterium is common in harmless sore throats. I ask special attention to this. The importance will appear later. In catarrhal inflammation of the conjunctiva, the bacillus fully virulent to animals is often found. It is strange, therefore, that diphtheria of the conjunctiva (already very susceptible through inflammation) is so rare, Baginsky, Meyer, and others state the bacillus (highly virulent to animals) to be common in the mucous membrane of the nose, associated with rhinitis, a harmless disease. It is remarkable that in so many cases of rhinitis, with virulent diphtheria bacilli, so few contract diphtheria. Todd and Washbourn observed among convalescents from scarlatina, an endemic rhinitis (that is, inflammation of the mucous membrane of the nose) without the formation of a membrane, without swelling of the glands, without fever, etc., etc. In all cases (51) they found the Klebs-Löffler bacillus, which was fatal to guinea-pigs. They note a series of cases with the true Klebs-Löffler bacillus occurring in children strongly susceptible (through rhinitis) as well as susceptible in general, because they had had scarlatina. Among these was not found a single case in which diphtheria occurred. Soerensen points out that diphtheria, following measles and scarlatina, is very fatal. Yet he found the perfectly fatal (to animals) Klebs-Löffler bacillus in 326 patients convalescent from scarlatina. In 85 per cent. there was not a symptom of diphtheria. In 15 per cent. there was a slight membrane. There was not a single case of croup, and not a single case of death. Stoos gives observations about many nasal catarrhs from the Berne hospital, and from different parts of Switzerland, where no diphtheria has occurred for years. The Klebs-Löffler bacillus was found almost without exception. No diphtheria, yet a very susceptible mucous membrane. Kanthack says: "Mention must be made of the numerous cases of fibrinous rhinitis in which diphtheria bacilli have been found." "Further, bacilli, resembling diphtheria bacilli, are found with the greatest frequency in many ulcerations of the skin, gangrene, stomatitis, cancrum oris, noma." He continues: "Todd's observation is a further contribution gradually gaining ground that the diphtheria bacillus is found in many lesions which are not diphtheria." On each of Koch's three tests the evidence against the specificity of the Klebs-Löffler bacillus is crushing, and there are a great many disbelievers. Kassowitz states: "It is now generally admitted that the Löffler bacillus is not the exciting cause of diphtheria" (Medical Press and Circular, June 15th, 1898).

Mr. S. F. Smith, M.R.C.S.

29 Oct. 1907.

13230. (*Sir John McFadyean.*) Is that an editorial article?—I do not remember; this is from notes made some time ago. It could be ascertained by looking up the Medical Press and Circular of 1898.

13231. I only wanted to know what importance to attach to the statement?—The statement is: "It is now generally admitted that the Löffler bacillus is not the exciting cause of diphtheria. That is the opinion of Kassowitz. I turn now to the positive objections. The antitoxin treatment depends on the assumption that the Klebs-Löffler bacillus is the cause of the disease. We have also seen that by all the recognised tests this assumption has been proved false. There remains the practical question: What have been the results? These results must be looked at in the form of statistics. These statistics may be examined in two ways. We may ascertain the total deaths from diphtheria in a country for each year. This is called the absolute mortality. We may also take the figures of patients in hospitals, and note the deaths in each hundred cases. This is called the case mortality. Before going further, we must look at several most important sources of fallacy which might vitiate any conclusion. They are the following:—(1) The fact that statistics have been made with selected cases. (2) The fact that the severity of diphtheria varies with time and place to an immense degree. When we have scrutinised these points we shall see that they are formidable enough to deceive even an impartial inquirer, and to enable a partisan who disregards them to prove either that antitoxin has saved or has killed an enormous number of diphtheria patients. Then statistics have been made from selected cases. We may get favourable but misleading results for a remedy by two methods of selecting cases. (*a*) We may eliminate severe instances. Roux, in the first statistics of antitoxin ever made, suppressed 7 per cent. of mortality by this means. Dr. Lennox Browne remarks in relation to this source of fallacy: "When this error is rectified the improvement due to antitoxin, as practised in the Metropolitan Infectious Fever hospitals for 1895 and 1896, is entirely dissipated." (*b*) We may include in our statistics an increased number of mild cases. Lennox Browne remarks on this: "The Klebs-Löffler bacillus being now recognised as an irrefragable test of diphtheria—the clinical criteria being often treated as subordinate—the numbers of cases of the disease are much greater than in former times." Tirard, in his book, "Diphtheria and Antitoxin," says: "Few diseases give rise to such frequent mistakes." He says also: "Some cases in which the bacillus is found to be present would otherwise give rise to no anxiety; while, on the other hand, in some cases of undoubted diphtheria, clinically, the bacillus is sought in vain."

13232. When you say that Dr. Lennox Browne says this and Tirard says that, are these your observations which you are making as the result of your own reading, or are you quoting it all from one article? It is difficult to follow what the evidence is?—I began to quote only here. I said Dr. Lennox Browne remarks in relation to this gross fallacy——

13233. Are you now reading from one of your own notes?—This is something I have already published.

13234. You are not going to read the whole of it?—I want to read the whole of it.

13235. It is quite unusual to read a long statement of many pages?—But I would like to point out that this question of antitoxin is one which has been so prominent in the controversy of vivisection—I have seen a good deal of vivisection controversy, and this point is always being brought up, and, so far as I can see, none of the witnesses who have been here before the Commission have any grasp whatever of the fallacies underlying these statistics.

13236. It is quite impossible to take in all these things mixed up with statistics and figures, and to follow them and to carry anything in one's mind. It can be printed as part of your evidence?—That is quite sufficient for my purpose. I ask this because of the very great importance of the question.

13237. We have been sitting here for many days, and we have heard, I think, almost all these points that

Mr. S. F. Smith, M.R.C.S.

29 Oct. 1907.

you have been taking, and, therefore, when you say that it is of vital importance that you should read these thirty pages, you are speaking of it as a person who comes freshly into this room?—I have read Dr. Martin's evidence on diphtheria, and his evidence is simply honeycombed with fallacies, and I have been extremely anxious to point these fallacies out.

13238. (*Sir John McFadyean.*) Has this been written since Dr. Martin's evidence?—No, long before.

13239. Would it not be much more useful and more convincing to this Commission if you would show us the fallacies that are so abundant in Dr. Martin's statistics?—Yes, I will.

13240. (*Chairman.*) When you began reading, I did not understand what you were busy upon. It is very unusual to read whole pamphlets?—I ought, perhaps, to have stated before that I was going to read a lot, and to have told the Commission the reason why I wished to do so, as this is a point in the controversy which is so much more important than practically all other points.

13241. Several witnesses have handed in to us pamphlets which they have written which they did not expect to be printed in the evidence before the Commission. Others have handed in long statements with figures, but not amounting to thirty pages, which have been incorporated in the evidence of the witnesses. This is a very strong demand upon us?—May I, then, say that I have here about fourteen pages of what I consider the most important evidence, which I have not read?

13242. You would prefer reading them to throwing them aside and dealing with Dr. Martin's evidence separately? Because we cannot have it both ways. You say that you want this specially read, as being an answer to Dr. Martin?—Yes.

13243. Then you would prefer that it should be printed?—Yes, dealing with the positive objections.

13244. Then it shall be done?—I ask special attention to this point, for it relates to a fallacy of the greatest dimensions. We have already seen that the Klebs-Löffler bacillus is found not only in perfectly healthy people, but also in numerous lesions which are not diphtheria, and among these, simple sore throats. We must remember that the believers in antitoxin are all believers in the bacteriological diagnosis. Consequently the statistics of serum treatment are made on selected cases—selected by the inclusion of trifling sore throats that by the clinical diagnosis would be excluded. I bring further evidence on this point. The antitoxin treatment was first tried at Paris in February, 1894, and was in general use in 1895. The following figures show how the serum treatment and the bacteriological diagnosis at once swelled the numbers of cases diagnosed as diphtheria. Coakley gives these statistics:

BOSTON.

Year.		Notified Cases.
	1891	831
	1892	1,353
	1893	1,465
Serum years.	1894	3,019
	1895	4,059

NEW YORK.

Year.		Notified Cases.
	1891	4,874
	1892	4,654
	1893	6,463
Serum years.	1894	9,155
	1895	9,925

BROOKLYN.

Year.		Notified Cases.
	1891	1,850
	1892	1,829
	1893	1,672
Serum years.	1894	3,812
	1895	4,277

According to the "Medical News," 1896, No. 25, there occurred in the Boston City Hospital the following statistics:—

Year.		Admissions.	Deaths.
	1893	419	203
Serum years.	1894	598	266
	1895	1,566	207

We see here a great increase in numbers diagnosed as diphtheria, while the absolute mortality is not appreciably changed.

From the Hospital of St. Ladislaus we get the following figures:—

Year.		Admissions.
Without Serum.	1893	213
	1894	224
With Serum.	1895 / 1896	1,046

We see here the diagnosed cases doubled. According to Kassowitz, there were treated by Baginski in 1894.

In the first quarter, without serum 86
In the second quarter, with serum 239

Gottstein gives the following table:—

Year.	Admissions to the Hospital.
1892	453
1893	454
1894	712

In Basle, from 1885 to 1894, the average annual notifications were 245. In 1895 and 1896 we find the number increased to 740. We need not pursue this part of the subject further. The evidence is overwhelming that the bacteriological diagnosis and the serum treatment have brought an enormous number of simple sore throats into the figures of diphtheria. To compare such statistics with statistics from which mild inflammations of the throat have been excluded lands us at once in a fallacy of the greatest dimensions. Now this fallacy the champions of serum ask us to ignore, as they ignore it themselves. I here finish with the first source of erroneous conclusions, and come to the second. The severity of diphtheria varies widely in time and place. If we counted the shipwrecks after a moderate gale, and again after a violent hurricane, we should find a difference in the figures. If we tried

to explain the difference without taking into account the difference in the two storms, it is obvious that we should be leaving out a somewhat important factor. Now, one epidemic of diphtheria differs in severity from another, as much as one storm differs from another. I proceed to prove this. Dr. Feilchenfelder gives the following figures of diphtheria mortality in Charlottenburg:—

Year.	Deaths.
1887	56
1888	11
1889	18
1890	32
1891	37
1892	79
1893	129
1894	47
1895	45
1896	24
1897	53
1898	64

Hellström says that at Stockholm in 1894 the mortality of 33 per cent. in the first quarter of the year sank to 6 per cent. without change of treatment. In the South-Eastern Hospital of London, the mortality in July was 37 per cent. In the following August it fell to 18 per cent. without change of treatment (MacCombie). Aub has pointed out that at Munich the mortality during six years oscillated between 6 and 14 per cent. According to Hahn, the mortality of Friedrichshain in some years differed by 18 per cent. from the mortality of other years (with no change of treatment). Buning gives the diagram in Fig. 1 for the twelve largest parishes in Holland. The reader will scarcely ask for more evidence that the virulence of diphtheria at one period of time varies widely from its virulence at another.

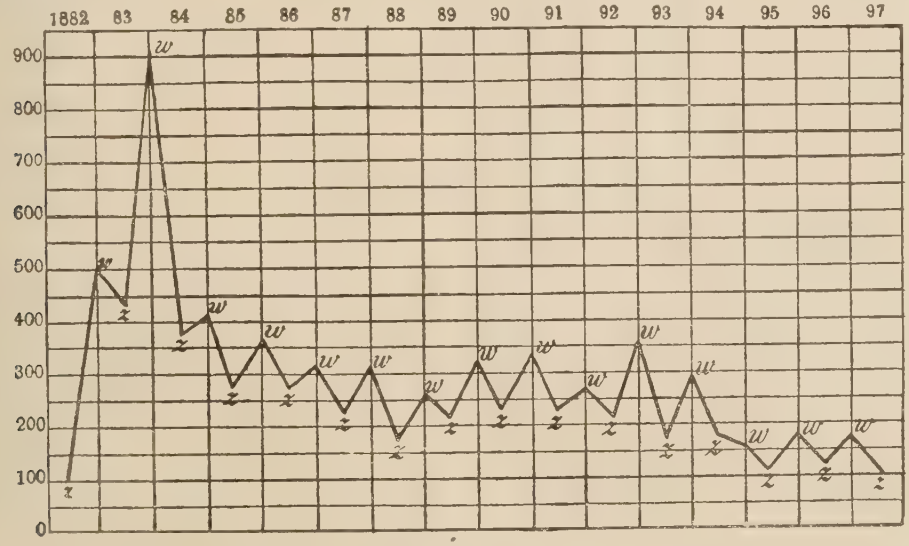

FIG. 1.

The causes of this variation are unknown. It is obvious that if we build up any argument on the assumption that the mortality of diphtheria would remain stationary, unless influenced by treatment, we are at once entangled in a huge fallacy. Yet this is exactly what the champions of serum ask us to do. And they ask it in face of all evidence to the contrary. Time is not the only disturbing factor. Place also has a mysterious influence. In 1888 Baginsky observed an epidemic in two villages side by side. Treatment and time were the same. In one place no patient died. In the other nearly all died. If the treatment had been different in each case a firm conviction in favour of one would have been established.

Rump, in Hamburg, gives the following table:—

The New Hospital.		The Old Hospital.	
Year.	Mortality.	Year.	Mortality.
1889	28 per cent.	1889	49 per cent.
1891	13 ,,	1891	52 ,,

We see to what a wide extent results will be affected by the selection of cases and the disturbing factors of time and place. Keeping these points in mind, we see how they throw light on the following remarks of Tirard: "Few diseases have been treated by such numerous remedies, and for every remedy a large percentage of successes has been claimed. It has been found that the drugs recommended were first greatly vaunted; that then they gradually fell into disuse. Perhaps they were completely forgotten, and a few years later they were introduced as novelties with the same extravagant praise and a similar list of successful cases." That is to say, when a new treatment was tried at a time when the mortality from natural causes was falling, the treatment got the credit. When the mortality again rose, the treatment was abandoned. The champions of various drugs were sincere in their belief, but they were deceived by ignoring the natural disturbing factors. I shall bring evidence that the believers in serum have been deceived in exactly the same way, and, moreover, have been led astray by one additional source of fallacy. Prior to the use of antitoxin, the advocates of different drugs were only misled by two factors—the disturbing elements of time and place. They could not be accused of introducing a new standard of diagnosis to flatter their figures. The antitoxin believers, on the contrary, based their statistics on the inclusion of an enormous number of mild cases brought in by the new bacteriological diagnosis. This we have already seen. There is another point of contrast. Other remedies, based on more favourable figures than those of serum, have never received a sudden world-wide attention. Roux, at the Hospital for Sick Children, Paris, made statistics on 300 cases from February to July, 1894. (I may note, *en passant*, that they were vitiated by every one of the sources of fallacy we have considered.) His report at once received a huge advertisement resounding throughout every civilized land. The treatment was soon adopted in most countries in 1894, and was in full swing in 1895. The explanation of why Roux's figures received such sudden fame whilst the better ones of others were neglected is obvious. Pasteur's

Mr. S. F. Smith, M.R.C.S.

29 Oct. 1907.

treatment of hydrophobia was generally believed in. The treatment of diphtheria by Roux (of the Pasteur Institute), was based on somewhat similar lines. The prestige of Pasteur threw a glamour over the new antitoxin remedy. Before looking at serum statistics there is a point to be noticed. The new remedy was introduced at the most favourable moment—when a decrease in mortality was well on its way. Besides a more rapid up and down variation in the virulence of diphtheria, there is a slower movement extending over years. This is clearly exemplified in Figure 1. That the severity of diphtheria had been declining previous to 1894 there is abundant evidence. Göttstein says of Berlin that the virulence increased from 1876 to 1883, then remained nearly stationary till 1886, and after this declined more rapidly, especially in the years 1890, 1892 and 1893. Bernheim says of this: "It is clearly shown that for eleven years we have been on the descending curve of a severe epidemic, and that, apart from the decline of absolute mortality, the severity of the cases has diminished, and this has caused a decrease of the case mortality." This view is endorsed by Soerensen, Heubner, Bötticher, and others. From 1885 to 1890 the total deaths in the Netherlands were 9,656. From 1890 to 1895 the figures were 7,808, showing a spontaneous decrease. *Just previous* to the advent of anti-toxin there was a special fall observed. According to Buning this occurred:—In Paris at the beginning of 1893. In Holland at the end of 1893. In German towns at the end of 1893. In Vienna at the end of 1893. In Stockholm it occurred in 1894, but without the use of serum. Looking at the figures of the Metropolitan Asylums Board, we see a continuous fall from 1889 (see Table below). Buning gives the following diagram of the mortality at Paris (Fig. 2):—

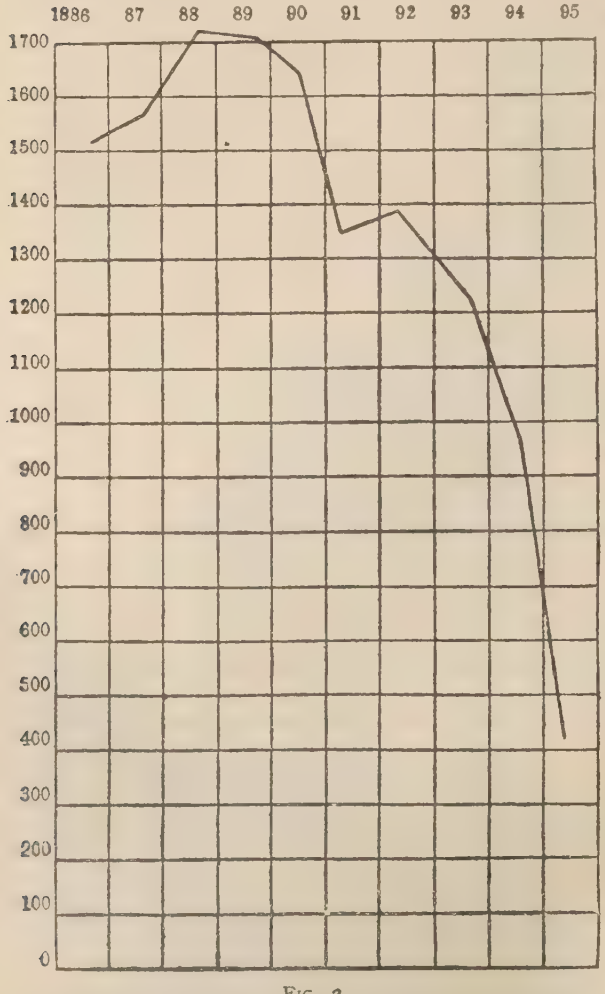

FIG. 2.

Looking at Fig. 2, we see that the spring of 1894 was a most favourable moment for assistance (from natural causes) in getting good figures. We have now considered the factors which, if disregarded, will vitiate any conclusions. We see the conditions necessary before a true comparison of different treatments can be obtained. They are:—(1) The place must be the same. (2) The time must be the same. (3) The statistics must not be aided by selecting the cases. We have seen that this has been done; sometimes by exclusion of severe instances, and, in all cases where serum statistics have been made, by the inclusion of an increased number of mild examples of diphtheria. (Roux's first figures were improved by exclusion of severe and inclusion of mild cases.) The only statistics that have been made under the proper precautions against error are those of Soerensen, of Copenhagen. They are as follows:—Of 51 cases treated with serum there died 17. Of 46 cases treated without serum there died 15; mortality in each case, 33 per cent. These are the only comparative figures existing on which the slightest reliance can be placed. To show the absurdity of making any comparison without regarding the sources of fallacy indicated above, I shall prove:—Firstly: That serum kills an enormous number of patients. Secondly: That serum saves an enormous number of patients. Taking the figures against antitoxin.—I shall examine first the absolute mortality—that is, the total annual deaths. It should be noted that absolute mortality involves one fallacy less than case mortality—viz., the variation due to place. The other two vitiating circumstances, however, operate in full force. *England and Wales.*—The figures of the Registrar-General show that for each million of the population the average annual deaths from diphtheria were, from 1881 to 1893 inclusive, 188. These were pre-serum years. From 1894 to 1900 the average was 269. These were serum years. *Trieste.*—Germonig gives the following figures of the mortality at the hospital:—

	Years.	Deaths.
Pre-serum years.	1892	59
	1893	87
	1895	297

In 1895 almost every case was treated with antitoxin. *New York, Brooklyn, and Boston.*—Coakley has shown that the absolute mortality in these places after serum treatment was as high as the worst years since 1832.

ST. PETERSBURG.

	Year.	Deaths.
Pre-serum years	1892	333
	1893	378
	1894	1,027
Serum years.	1895	807
	1896	1,118
	1897	1,905

Basle.—Here there died on an average, from 1885 to 1894, 29 patients. There died in 1895, 65 patients; in 1896, 49 patients. No comment on the absolute mortality is needed. The figures speak. Taking the Case Mortality.—For the sake of comparison we take the mortality obtained by Roux at the Hospital for Sick Children, Paris, when serum was first used. This was 26·0 per cent. Against this we give the following results obtained without serum. Neumeyer treated 1,000 diphtheria patients in 15 years with only six deaths. Mortality, 0·6 per cent. Lueddeckens used cyanide of mercury, with the results shown by the following table:—

Year.	Number Treated.	Deaths.
1893	18	0
1894	14	0
1895	32	1
1896	17	0
Total	81	1

Mortality, 1·23 per cent.

Neumann, of Potsdam, gives the following figures, obtained without serum, and compares them with serum therapeutics:—

Year.	City Infirmary.	St. Joseph's.	His own Practice.
1894 - -	35·5 per cent.	36·9 per cent.	·6 per cent.
1895 - -	9·0 ,,	14·8 ,,	3·3 ,,
1896 - -	14·3 ,,	2·3 ,,	·0 ,,
1897 - -	12·0 ,,	7·3 ,,	·0 ,,
1898 - -	8·4 ,,	11·1 ,,	8·0 ,,
1894–98 -	Average, 15·4	Average, 13·6	Average, 1·6

Göttstein and Schleich quote the statistics of Feer, who in 4,000 cases from 1875 to 1891, had a mortality of 12·7 per cent. Aub has shown that at Munich the mortality for six years oscillated between 6 and 14 per cent., without serum. Hulol and Goubeau, employing perchloride of mercury, report a mortality of 4·7 per cent. Kastorsky, using an alcoholic solution of menthol, treated 37 successive cases without a death. This treatment yielded the same good results to Trutovsky. What shall we say of these figures? What shall we say of the enormously increased totality of deaths since the introduction of serum? What shall we say of the low mortality shown in many cases without serum? If we take up the utterly indefensible position of the antitoxin champions in ignoring the sources of fallacy, we must conclude that serum kills an enormous number of patients. The believers are hoist on their own petard. Having proved that antitoxin kills, we can just as easily prove that it saves. We do this in the same manner—by refusing to consider the factors which falsify our conclusions. Taking now the figures in favour of serum, I have mentioned previously that medical opinion in England has been moulded by one set of statistics. They are those of the Metropolitan Asylums Board. I give them:—

	Year.	Mortality.
Pre-serum Years.	1889 - - -	40·74 per cent.
	1890 - -	33·55 ,,
	1891 - - -	30·31 ,,
	1892 - - -	29·51 ,,
	1893 - - -	30.42 ,,
	1894 - - -	29·29 ,,
Serum Years.	1895 - - -	22·85 per cent.
	1896 - - -	21·20 ,,
	1897 - - -	17·79 ,,
	1898 - - -	15·37 ,,
	1899 - - - -	13·95 ,,
	1900 - - -	12·01 ,,

We observe here a continuous decline of mortality, with two falls more abrupt than the others, one in 1890 of 7·19 per cent. and the other of 6·44 per cent. in 1895. These figures have been triumphantly heralded as proof of the value of antitoxin. Let us ask the serum believers for an explanation of the decline, and note the reply. I put the matter in form of question and answer. *Question:* What was the cause of the continuous fall from 1889 to 1895? *Answer:* Natural causes—decreasing virulence or increased number of mild cases sent to hospitals. *Question:* What was the cause of the sudden decline of 7·19 per cent. in 1890? *Answer:* As before. *Question:* What was the cause of the continuous fall from 1894 to 1900? *Answer:* Serum. *Question:* What was the cause of the fall of 6·44 per cent. in 1895? *Answer:* Serum. *Question:* What evidence have you that the decline after 1894 was not due to the same causes as the decline in previous years? *Answer:* We offer you the testimony of our inner consciousness. In relation to the much-quoted figures of the Metropolitan Asylums Board for the years 1889 to 1900, let us look at the figures of the Metropolitan Asylums Board for 1903. I quote from the "Hospital" of August 20th, 1904: "It is to be observed that out of 530 cases of diphtheria admitted to the North-Western Hospital 172 were treated without antitoxin, and they all recovered, while of the remaining 358 treated with antitoxin 42 died, and of the entire 5,422 cases treated in the Board's hospitals 4,139 were treated with antitoxin, of whom 10·18 per cent. died, whereas of the 583 cases treated without antitoxin only 1·88 per cent. ended fatally." More figures can be given in favour of serum. In several places a fall in case mortality was noticed after the introduction of antitoxin. The most quoted is that observed at the Hospital for Sick Children, Paris. There the average mortality for four years had been 51·7 per cent. In the first five months of the use of antitoxin the figures fell to 26 per cent. During the same period at the Trousseau Hospital, Paris, the mortality was 63·2 per cent. without antitoxin.

Mr. S. F. Smith, M.R.C.S.

29 Oct. 1907.

Hospital for Sick Children.		Hospital Trousseau.
Time.	Mortality.	Mortality.
1880–1893 - -	51·7 per cent.	—
Five months of 1894	26 per cent.	63·2 per cent.

At first sight this looks very convincing in favour of serum. But when we have looked at all the factors we shall see that the comparison is worth nothing. To compare the mortality of one period of time with that of another we have abundantly proved to be useless. I have already quoted examples where two places side by side showed differences of mortality greater than in this instance, without difference of treatment. These criticisms are far from being all. At the Hospital for Sick Children the statistics were under the care of Roux, the bacteriologist of the Pasteur Institute. The cases were selected. Roux admits that he suppressed twenty cases followed by death before treatment could be administered. If included, his mortality would have been 33 per cent., and this was not the only way in which his statistics were helped. All sore throats showing the Klebs-Löffler bacillus were included in the figures. All without it were excluded. We have already seen that this bacteriological diagnosis brings an adventitious number of mild cases into statistics, and excludes severer ones. Roux's figures are vitiated by all the fallacies we have considered. (1) The fallacy of time. (2) The fallacy of place. (3) The fallacy of excluding severe cases. (4) The fallacy of including an increased number of mild cases. The Commission have now the evidence before it, and must judge for itself whether antitoxin is of value, or whether it is to be classed with those remedies for diphtheria which "were first greatly vaunted, then fell into disuse . . . . and a few years later were introduced again as novelties, with the same extravagant praise and a similar list of successful cases." I conclude with an example of this praise: "The terror inspired by diphtheria has been banished, as that inspired by small-pox has been banished by vaccination."

13245. (*Mr. Ram.*) What is the date of this pamphlet?—The date is 1904, but it has been somewhat brought up to date recently. It has been recopied from the volume "Fruitless Experiments," published in 1904, with some few additions to it.

13246. (*Sir Mackenzie Chalmers.*) The first edition was in 1904?—Yes.

13247. It has been republished with corrections in 1905 or 1906?—I think in 1906. I should like though to just point out one fallacy at least, which is so constantly occurring in these statistics of diphtheria.

Mr. S. F. Smith, M.R.C.S.

29 Oct. 1907.

13248. (*Chairman.*) Is this contained in the passage you have just put in?—Yes, but it applies to Dr. Martin's figures, and the fallacy of Dr. Martin's figures could only be seen after very careful examination of my statement, and might be overlooked.

13249. Will you just refer us to Dr. Martin's statement, and deal with that separately, because we cannot have it both ways?—It is on page 215 of the Third Report of this Commission. Firstly, taking the figures of the Metropolitan Asylums Board, he has put these figures previous to the introduction of the antitoxin in a misleading manner. He has lumped the years 1888 to 1893, and, as you will see, I have given the figures for each year instead of lumping them. By lumping them he leaves out of consideration the fact that there had been from year to year a decrease—that the mortality was already on the decline every year, which might be inferred but certainly is not apparent from the way in which Dr. Martin has given the figures.

(*Mr. Ram.*) There was not a universal decrease; there was a rise again in the year 1893.

13250. (*Chairman.*) But I think with some slight variations it steadily declined?—Yes, that is so.

13251. (*Sir Mackenzie Chalmers.*) Then, as soon as you get to the serum years it goes down with a jump?—I point out that there was just as big a jump from 1889 to 1890 as there was in the first year of the serum. But I wish to point out one fallacy for this reason, that it is a fallacy occurring over and over again, and always coming up, which nobody seems to have recognised, which fallacy is in a lot of the figures which Dr. Martin has given here. If you take the mortality in 1895 it is 22.8 per cent. If you take it in 1896 it is 21 per cent. That is in the figures of the Metropolitan Asylums Board. Everybody assumes, and we are always asked to take for granted, that this reduction of practically 2 per cent. has been due to the antitoxin, but everybody seems to overlook that you are comparing one antitoxin year with another antitoxin year, and if you keep on like that your error becomes greater and greater as you go along.

13252. I do not follow. Which is the first error?—The first error is that 1895 was an antitoxin year, and that 1896 was also an antitoxin year, and that by comparing an antitoxin year, 1896, with an antitoxin year, 1895, it is assumed that the improvement in the figures was due to the antitoxin. For the life of me I cannot see why it should be. You are comparing it with another antitoxin year.

13253. (*Mr. Ram.*) But you find a rise afterwards in 1901?—That shows that there must have been some other cause.

13254. They are both antitoxin years?——

13254A. (*Chairman.*) No doubt the figures do not absolutely prove one thing or the other, but the suggestion on the other side is that if you find antitoxin being taken up and used more and more in hospitals you find a greater decrease?—I do not think that has ever been shown. I do not think that it is because a larger percentage of patients have been treated by antitoxin. I do not think that has ever been alleged.

13255. I cannot say speaking from recollection. I am only pointing out that there may be an explanation on both sides; on the one that this is a natural decrease going on which would have gone on without the serum, and on the other that the serum, having been introduced for the first time in 1895, the probability is that it was not introduced so fully in the first year as it became afterwards?—I think it was pretty fully introduced in the year 1895.

13256. On the other hand these gentlemen will say that the decrease was not a natural one. I am not deciding which way it was; I am only pointing out that we have these figures before us and we have had these explanations on both sides before us. Is that your evidence upon the diphtheria antitoxin?—Yes, it is.

13257. Is there anything you wish to add?—I am sorry that the Commission do not wish to hear me fully on the question.

13258. You really must not say that. No witness has been invited to read a whole pamphlet to us?—Quite so. I quite admit that it is very long and it may be exceptional.

13259. We cannot hear it both ways. We cannot have the whole pamphlet printed and at the same time hear the substance of it given orally. We gave you the choice?—If I make certain criticisms now on Dr. Martin's evidence before I have pointed out certain general fallacies, I do not see how the Commission will understand it.

(*Sir John McFadyean.*) Might I suggest to the witness that he might keep his mind easy about Dr. Martin's statistics, because some of us are pretty certain to ask for his criticisms upon some of those statistics which do not seem to be touched, and he may have abundant opportunity to disclose the particular fallacies contained in Dr. Martin's statistics.

(*Witness.*) It is that opportunity that I want.

13260. (*Chairman.*) That you will have in questions put to you?—Then I shall be quite satisfied.

13261. (*Sir William Church.*) I think in your *précis* you have referred to this book that you have published, "Scientific Research"?—Yes, I am the author of it.

13262. It was, I suppose, written for the purpose of informing the public of what went on in physiological and pathological laboratories?—Yes.

13263. What is the meaning of this: "A View from Within"—that is on the cover and also on the title-page inside?—It means a view from a person who has been inside a laboratory, a view from inside the laboratories by a person who has been inside a laboratory.

13264. I presume that is what is meant; a person who is conversant with all the work that goes on in laboratories?—Yes.

13265. But then from your preface in this book it does not appear that you were very conversant with all the work that goes on in laboratories. Have you ever worked in a physiological laboratory?—Yes, I have.

13266. Where?—At Strasburg and Brussels.

13267. You were a month in Brussels. You said in your evidence, I think, you were a month in Brussels?—Perhaps I did; I was about a month in Brussels or more. I was several months in Brussels, as a matter of fact.

13268. I thought you said also that you worked a month at the Pasteur Institute?—Yes.

13269. And at Strasburg?—I was about three months at Strasburg.

13270. When working in these institutes were you regularly working in the laboratory at any special point?—At that time I had some idea of going up for the fellowship, and I was working on the muscles of dead frogs. I did no experiments on living animals myself. I did the common experiments on dead frogs.

13271. Have you ever worked in any English laboratory?—No, I have not.

13272. Are you conversant with English laboratories?—No, I am not.

13273. Then should not you have put on this book "A View from Within of the Strasburg and Brussels Laboratories," so that the public should have known what laboratories you had a knowledge of?—I presume that if the public see the outside of a book they will likewise read the inside of the book. I did not see any necessity to put it on the outside of the book.

13274. But it is in the inside also, on the title page?—I presume that, if people read the book, they would get a fair idea of what the book is from reading it. I did not attempt to put a full description of the book on the outside.

13275. I think you were a Licentiate of the Society of Apothecaries first of all?—Yes.

13276. About 1884?—About 1884.

13277. You were then in practice between 1884 and 1900?—Yes, I was, to 1899.

13278. Then you retired from practice?—Yes.

13279. And during those 16 years you were not working in either a foreign or an English laboratory?—I was in general practice from 1884 to 1899.

13280. Still, you had no practical experience then of what was going on in laboratories, either foreign or English?—No.

13281. And, in fact, the whole of your experience has been a month at the Pasteur Institute, a month at Brussels, and a month at Strasburg?—I was about three months at Strasburg.

13282. But there you were not working in labora-

tories; you were only just attending?—No, I was working in the laboratory.

13283. At some special subject?—On dead frogs.

13284. (*Mr. Ram.*) Did you ever experiment on any living animal?—I never operated on a living animal in my life.

13285. (*Dr. Gaskell.*) Was that in Goltz's laboratory?—Yes.

13286. (*Sir William Church.*) And on that experience of yours you think that you are entitled to say you were in a position to draw back the curtain disclosing the machine?—Yes, I think so.

13287. I am referring to what you say in the preface: "A celebrated lawyer addressed a jury at length to prove that the wheels of a certain machine could not possibly be more than a certain size. His opponent was expected to argue at length in reply. Instead of doing so he merely drew aside a curtain disclosing the machine and remarked—'Gentlemen, there are the wheels'" ?—Yes.

13288. Considering that this was for the English public, that is rather a strong thing to say by a person who has never worked in English laboratories, is it not?—It does not refer to English laboratories. A book speaks for itself. The preface does not speak for the whole book. The book itself must speak for itself.

13289. I am only alluding to that passage in the preface?—The book speaks for itself. I did not intend that a person should read the preface only without the book and form a wrong judgment from the preface.

13290. Then turning to the book, that being the case, I should like to ask you this: You were working only on frogs abroad. On page 47 of your book you definitely make these statements. You say, "Curare is used daily throughout England." Do you think that you were in a position to say that with your experience?—Yes. I did not say that it was from my personal experience.

13291. As you told us to-day in your evidence, in five years you have only been able to find about 100 instances of its use?——

(*Sir John McFadyean.*) No, about 10 per cent.

(*Witness.*) The reason is this: I have taken, as I have mentioned already, the "Journal of Physiology" for five years and I found that the proportion of cases of physiological experiments in which curare is used, and inasmuch as from that it appears that in cutting experiments it is used in 10 per cent., if it was used in 10 per cent. of these purely physiological experiments, it was not certainly an exaggeration to say that it was in daily use. That would practically amount to 7 per cent. of the physiological experiments in England for a year, and take 7 per cent. of those I think you would have more than one a day under curare.

13292. (*Sir Mackenzie Chalmers.*) That is the inference which you draw from the fact that in 10 per cent. of the cases reported in the "Physiological Journal" curare was used?—Yes.

13293. (*Sir John McFadyean.*) Along with anæsthetics?—Yes.

13294. (*Dr. Gaskell.*) Ten per cent. of the cutting cases?—Yes, 10 per cent. of 71 per cent.

(*Sir Mackenzie Chalmers.*) I do not think that follows myself.

13295. (*Sir William Church.*) Of course this book is for the public, and purports to be written by a person daily working in pathological and physiological laboratories, and as an authority. With regard to the use of curare, on page 32, you give us your opinion, the result, of course, of observation of your own—"That Bernard was right in believing,"—curare—"to greatly intensify pain"?—Yes.

13296. But have you ever worked on the subject?—Worked on what subject?

13297. On the subject of trying to find out whether curare greatly intensifies pain?—No, I have not tried to find that out.

13298. Therefore you are merely repeating what other people have said?—Yes.

13299. You give it, as you say, "That Bernard was right in believing it to greatly intensify pain is clear also"?—I do not know what the context is there. The word "also" refers to some context which you have not given me. If you give me the context I shall see the reason for it perhaps.

13300. The whole context is this: "We see clearly that the opinion of Bernard and all physiologists is correct—that curare is not an anæsthetic. That Bernard was right in believing it to greatly intensify pain is clear also." That is your statement on page 32, Chapter IV. Therefore you had no reason of your own for that definite statement?—Yes, I certainly had.

13301. It is only repeating what you thought was the opinion of others?—I am repeating the opinion of Claude Bernard; but I do not know whether I put in the context or not the reason for believing that it intensifies pain. "We see clearly that the opinion of Bernard and all physiologists is correct—that curare is not an anæsthetic. That Bernard was right in believing it to greatly intensify pain is clear also." Then what follows goes on this way: "For the motor tracts being shut off, the whole of the stimulus goes to the sensory centre." That is the reason for the statement.

13302. But that is not from any work of your own?—No, it is not. I do not profess it to be. I never said that it was.

13303. Then you go on to mention, if you will turn to page 36, that you saw an experiment at University College, London, on October 19th, 1900, by Professors Starling and Bayliss. This is also with regard to what you say about curare. You say: "When I first saw the animal (a small dog), he was motionless under curare. A hole had been cut in the windpipe, and the bellows kept up artificial respiration. At each stroke of the bellows a little ether was pumped in with the air—a much feebler blast than that used at Strasburg." How did you arrive at that knowledge?—What knowledge do you mean?

13304. That "a little ether was pumped in with the air—a much feebler blast than that used at Strasburg"?—By the sense of sight, and the sense of smell

13305. Nothing further than you thought that because you did not smell more ether?—No. The sense of smell was as to the nature of the anæsthetic.

13306. And the amount of the anæsthetic?—And the amount of the anæsthetic by the bellows and the bubbling. By watching the apparatus.

13307. You judged it then without either inquiring from Professor Starling or Professor Bayliss of the amount, or perhaps even seeing signs of Woulff's bottle or anything?—The bottle was in sight. At Strasburg they had the waterworks. There was a very powerful blast of air sent through the ether, and it was simply a matter of eyesight and observation that at University College the blast was much feebler.

13308. (*Sir Mackenzie Chalmers.*) Was it a lecturer's experiment or a scientific experiment?—After the lecture certain senior students were called in to see the experiment.

13309. (*Sir William Church.*) You really had no knowledge at all?—It was not a question of knowledge. It was a question of the eye.

13310. (*Chairman.*) I understand you to say that you measured it by your eyesight and your memory of what had taken place at Strasburg?—Yes.

13311. In neither case did you ascertain what the precise quantity or strength was?—No, not exactly. It was very easy to see. If I saw some person pouring water out of a glass and another out of a pail I should know that more water was poured out of the pail than out of the glass without measuring in either case.

13312. Do you wish to compare those two cases?—No, it is an exaggerated comparison.

13313. (*Mr. Ram.*) It is your suggestion that the animal was not sufficiently anæsthetised. Is that what you mean?—The suggestion is that it was very probably insufficiently anæsthetised.

13314. (*Sir Mackenzie Chalmers.*) Was the animal killed at the end of the experiment?—We were turned out of the room after being there about half an hour. I saw nothing more of the animal.

13315. (*Mr. Ram.*) How do you mean that you were turned out?—Well, it was time to go.

13316. (*Sir William Church.*) Here you say definitely (and this is for the information of the general public that this book is written) that morphia is not an

Mr. S. F. Smith, M.R.C.S.
29 Oct. 1907.

anæsthetic. Surely as a surgeon you do not mean to tell me that you cannot render an animal unconscious with morphia?—When I wrote this book I made that statement on certain authorities. One was the authority of Dr. Mitchell Bruce in his work on "Materia Medica," and Sir Lauder Brunton, who classify morphia among the narcotics.

13317. That is quite a different point?—I was giving you my reason for making the statement. Another reason was the statement by Professor Rutherford before the last Royal Commission, quoting the opinion of Claude Bernard that in animal experiments morphia was not an anæsthetic. Those were my reasons for making that statement in this book. Since then I have had reason to believe that morphia given in a lethal dose may cause unconsciousness.*

13318. But you would not tell the Commission, as some witnesses have, that you cannot render an animal unconscious with morphia?—Since I have written this book I have come to the conclusion that morphia may be used as an anæsthetic in a lethal dose.

13319. There is one other question that I should like to ask you with regard to this book. You say on page 36: "It is clear that in curarised animals anæsthesia is a practical impossibility." This is a book for the general public?—Yes.

13320. What really did you mean by that?—I will repeat what I said a little while ago were the reasons, which I have already given you; but as you ask for it again I will give it again; that is to say that when curare is given the guides which exist in anæsthetising a human patient are absent.

13321. But surely has not the person who is giving an anæsthetic to a curarised animal a very much better guide by knowing the quantity of anæsthetic he is administering?—No, the quantity of the anæsthetic is an unsafe guide, because my observations have been——

13322. But you have never made any observations?—I have seen experiments.

13323. That is a different thing from making experiments yourself?—That is just as good. Looking on at an anæsthetised animal is just as good to me for observing as if I gave the anæsthetic myself.

13324. Unless you have really made inquiries you do not know what amount of anæsthetic the animal is receiving?—Inasmuch as I have seen animals anæsthetised and observed the effects of a fixed quantity of anæsthetics upon these animals, I was in a very good position to judge.

13325. I will not ask any further about that. I should just like to ask you one or two questions on your evidence which you have given to-day. Was anything known as the cause of myxœdema before experiments were made on animals?—Yes, it was known from clinical experience that after the removal of the thyroid, symptoms of myxœdema arose.

13326. Even granting that, does that tell us the cause?—It may not tell us everything, but it gives us a very good idea that something was elaborated in the thyroid which in healthy people prevents myxœdema. That is the inference.

13327. You say it is so simple that one who runs could read?—Yes.

13328. But simple as it was it had never been discovered?—What had never been discovered? You say "it." What do you mean by "it"?

13329. I mean that the importance of the thyroid gland in our economy had never been discovered before experiments on animals were made?—Excuse me. It had been discovered by these operations on the thyroid in which the thyroid was removed and myxœdema supervened. So that this much was discovered by those clinical observations that something was elaborated in the thyroid which prevented myxœdema. If nobody ever thought of that I can only say that everybody was very stupid; it seems to me so simple.

13330. Nothing was discovered. It was observed that in certain cases this condition did follow the removal of the thyroid, but it was not known at all why it did follow?—Excuse me, I think it was known from a reasonable inference, because it was the absence of the thyroid.

13331. (*Sir John MacFadyean.*) Was the healthy thyroid ever removed in any of these experiments?—I do not think so.

13332. How can you infer that it was the absence of the thyroid. It might have been an antecedent disease of the thyroid?—For this reason: that although there had been some hypertrophy of the thyroid or some of the tissues, part of the thyroid, at all events, there was no myxœdema, but when the thyroid was removed there was myxœdema.

13333. That only proved that hypertrophy would not cause myxœdema, but I do not see that excising a diseased gland could prove that the absence of normal thyroid would cause myxœdema?—It seems to me a very simple deduction, that if with thyroid of any kind, whether diseased or not, you have got first no myxœdema, and then, if you remove the thyroid and myxœdema supervenes something has gone. It seems to me a simple deduction.

13334. (*Sir William Church.*) Even that would not have given us the knowledge of the remedy how to treat it. It was the finding that removing healthy thyroids in animals produced symptoms similar to myxœdema in man that led us to think that it might be applied artificially by feeding with thyroids?—You evidently do not agree with me that it was a simple deduction from the removal of a hypertrophied thyroid that it was simply the absence of the thyroid which was the cause of myxœdema. I say that was a simple deduction; you say it was not. The only comment I have made upon that, is that if that was the case with those people at that time, they did not show much intelligence.

13335. It was a deduction that was not made, anyhow, until after experimentation on animals?—That may be, that is quite possible; but if the deduction was not made I maintain that it showed gross stupidity.

13336. I should like to ask you one or two questions on diphtheria. Do you believe that there is such a specific disease as diphtheria?—Yes, certainly.

13337. I do not gather from what you were reading about the different conditions whether you did or did not. You do think that there is a specific disease called diphtheria?—Well, I do not know whether there may not be some varieties. That is a very difficult question. I do not think that anybody could answer that question whether there may not be some varieties.

13338. But still, there is such a disease?—There is such a disease as diphtheria.

13339. Which can be communicated?—From one person to another.

13340. Which can be communicated to animals?—I think the evidence is not sufficient to show that the disease which is communicated to animals is really the same disease.

13341. You are not clear that what is communicated to animals is diphtheria?—No, I am not.

13342. But that also is a specific disease which kills the animal?—Undoubtedly.

13343. And that can be communicated to animals?—Yes.

13344. Do you know how antitoxin is standardized?—No, I do not.

13345. And yet you give an opinion about the value of the antitoxin?—Yes.

13346. Then you are not aware of how the antitoxin is standardized?—No, I do not know how it is standardized.

13347. And how you have to find out what quantity of the antitoxin protects an animal from this communicable disease. You were not aware of that?—I was aware, generally, that there was something of the kind, but the details of these animal experiments I am not acquainted with.

13348. But you were aware that there was something of the kind?—I was aware that there were experiments.

13349. How do you explain to yourself that an animal that is poisoned with toxin, if it receives the antitoxin in sufficient quantity takes no harm?—I am unable to give any explanation of it.

13350. You do not deny that it is the case?—No, I do not deny it.

13351. But you give no explanation?—No.

13352. Have you had any experience of diphtheria yourself?—Oh, yes, a certain amount as a general practitioner.

* *See Question 4133 of Evidence before Royal Commission on Vivisection, 1875.—S. F. S.*

13353. Before or after the introduction of the antitoxin?—It would be chiefly before.

13354. You have had none since?—No.

13355. Have you had much experience of diphtheria?—Well, after having been in general practice about 15 years I suppose I must have seen a good many cases. I could not say how many.

13356. Did you often have to do tracheotomy?—I never had to do it once.

13357. Then you were fortunate in not seeing very severe cases?—Yes.

13358. Could you mention to the Commission the name of any one who has had a large experience of diphtheria, before and after the introduction of the antitoxin, who thinks it is useless?—You mean any individual?

13359. Any individual who has had individual knowledge and large experience both before and after the introduction of the antitoxin, who thinks that the antitoxin is useless?—I would mention Soerensen of Copenhagen, who made some very interesting experiments at Copenhagen. He recognised all the fallacies which exist underlying these diphtheria statistics: the fallacy of time; the fact that the virulence varies from time to time; the fact that the virulence varies in two places at the same time; and also he recognised the factor that there has been a selection of cases. Soerensen guarded against these as far as possible. He treated certain patients in the same hospital at the same time, and he guarded against a selection of cases, and he got about the same percentage of mortality in each case.

13360. He was in charge of the diphtheria hospital?—I presume he was physician to the hospital.

(*Sir John McFadyean.*) Could you give us the number of cases and the date of his report?

13361. (*Sir William Church.*) I was unacquainted with his observations. I do not know his name. Where has he published it?—I have taken that apparently from "Die Diphtheriekrankeit" by Buning of Haarlem.

13362. (*Sir John McFadyean.*) What is the date?—I cannot give the date at the present moment, but it is about 1900, somewhere about there, approximately.

13363. Cannot you give us the number of cases on which Soerensen's conclusions were based?—Yes, I think I can. I am just trying to find it.*

13364. (*Sir William Church.*) You have not given the date in the Bibliography at the end of your pamphlet, so perhaps you have not got it?—I have the book at home somewhere.

13365. It does not matter in the least.

13366. (*Sir John McFadyean.*) In your evidence you offered some opinions with regard to the difficulty of keeping wounds inflicted on animals surgically clean. Is that opinion justified by your own experience?—It is only as regards my own dog.

13367. It will probably satisfy me if you will say that it is founded on observations made on your dog?—Yes.

13368. You have no extensive experience?—I have no extensive experience on that point.

13369. Would you abandon your present opinion if you were told on good authority that operations of most serious kinds on the lower animals are performed in thousands, including opening the abdomen, in veterinary practice, and that the wounds heal by first intention just as in human beings?—I think it is possible.

13370. Does not that dispose of your contention that in inoculating animals for physiological experiments it is difficult or impossible to ensure the wounds healing by first intention?—You said "veterinary practice" just now. I was speaking more particularly of dogs in physiological experiments. If a dog can get at the dressing or tear it off with his paws it will do so.

13371. You do not suggest that a dog behaves differently to a physiologist and to a veterinary surgeon assuming that the wound is the same?—No, I do not, of course.

13372. Will you take it from me that in a veterinary practice dogs frequently have extensive recent wounds inflicted upon them left uncovered, and that they display no tendency whatever to tear them open?—If a veterinary surgeon told me that from his experience I should accept it.

13373. You find nothing incredible in that?—No.

Mr. S. F. Smith, M.R.C.S.

29 Oct. 1907.

13374. It is simply in agreement with the fact that aseptic wounds of human beings are comparatively painless?—Yes.

13375. You also offered us some opinions with regard to the difficulty of anæsthetising dogs. Is this your own dog again that has been anæsthetised?—No.

13376. Will you tell me how many dogs you have anæsthetised or seen anæsthetised?—About seven or eight.

13377. I notice that you said in a paragraph of your *précis* "*The uselessness of vivisection.*" Am I to understand that you contend that absolutely nothing useful for human or veterinary practice has ever been learned by vivisection?—I have not gone over the whole ground.

13378. Why did you head it "uselessness"?—The "uselessness" referred to what is contained in the rest of the *précis*.

13379. It is to be restricted to the special diseases that you deal with in your *précis*?—Yes, which I have examined.

13380. You do not offer any opinion with regard to other alleged instances of benefit to men and animals derived from vivisection?—No, because I have not examined them.

13381. We have had evidence given to us here, I may say, that a great deal of useful knowledge for the treatment of farm animals has been got from vivisection. Are you disposed to deny that?—I am disposed to regard it with very grave suspicion from my examination which I have made on these subjects. When I have seen the confident statements that have been made and have examined the experiments and found them so different from the confident statements, I gravely suspect the statements

13382. I would like to go in a little detail into any one of the cases that were mentioned, if you will tell me what are the grounds for your suspicion that the facts are misrepresented, or the conclusions not well founded. Take any animal disease that you like as to which you say you have gone into the evidence. Or perhaps I will suggest one or two to you; but I would rather you would name the animal disease yourself?—Are you speaking of animal diseases.

13383. Yes, certainly?—I beg your pardon; I misunderstood you. I thought you were referring to human diseases.

13384. No, to animal diseases?—I know nothing about animal diseases.

13385. You are not disposed to deny that it may be a fact that knowledge of great value for the treatment of animal diseases has been obtained by experiments upon animals?—I would rather not express an opinion upon that because I know absolutely nothing about it.

13386. But you do hold a very strong opinion that drug experiments on animals intended to throw light on the action of the drugs on men are useless. You have expressed that view?—Yes.

13387. You have cited some instances in which particular agents, poisons or medicines, have a different action on men and on some of the lower animals?—Yes.

13388. Do you want this Commission to believe that that is the rule or the exception?—I wish the Commission to believe that there are a very large number of drugs in which this does occur, and supposing it could be shown that there are 10 times as many cases in which the drug agrees as in which it disagrees, I say if in one-tenth it did not agree it would be very dangerous to argue from animals to man.

13389. But will you answer my question, please. Do these cases that you cited to us constitute the rule or the exception. My point is this. You contend that in a general way it is useless to make drug experiments on animals intended to throw light in advance on the action of these same drugs on man, and you cited to us some admitted instances in which the drug acts differently on the lower animals from what it does on man. I ask you whether you wish the Commission to believe that these cases represent the rule or constitute the exception?—I could not tell you that. It is quite possible that it may be in a great minority of cases.

13390. If you had answered otherwise I intended to ask you how you would explain the extraordinary fact that the veterinary pharmacopœa is practically the same as the human except with regard to doses. Are you aware of that?—No, I was not aware of that fact.

* *See Answer to Question 13344, p. 15. S.F.S.*

Mr. S. F. Smith, M.R.C.S.

29 Oct. 1907.

13391. You would not for a moment deny that?—If you say so I would not.

13392. I am not giving evidence, but I do say so?—Then I do not deny it.

13393. Coming to these specific cases in which you allege that unfounded claims have been made as to the benefit derived from vivisection, would you kindly turn to pages 223 and 224 of the Report of the evidence already given to us. You have got, I think, the Third Report there?—I have the page here.

13394. I want to direct your attention to this, because you quoted to us to-day some statistics on, I think, a very limited scale, and already not at all recent, from a book published by Dr. Melville. I want you to notice that the statistics given on page 224, if you look at that in the first place, relate to a large number of persons uninoculated and inoculated, there being among the uninoculated 10,000 and among the inoculated 1,700, and that the percentage of incidence of cases among the uninoculated was 14.14, and among the inoculated 2.05. Would you advise the Commission to disbelieve these statistics or to give no weight to them when they are asked to form an opinion as to the value of inoculation against typhoid fever?—The figures, as they stand, are certainly strongly in favour of it, but judging by the analogy of statistics in general, I should not like to say, off hand, that there might not be some vitiating factor.

13395. But that is not the question. Would you suggest to us what the vitiating factor is?—No, I am not able to do that.

13396. Would you give the same answer with regard to those figures on the preceding page, where there is an equally great difference with regard to the deaths among the inoculated and the uninoculated?—On the preceding page there are three.

13397. At the bottom of the page, I mean. These were officers, non-commissioned officers and men in the same regiment at the same place. There were 317 inoculated and two cases, and 164 not inoculated and 14 cases?—Two cases of what?

13398. Typhoid?—I see.

13399. Assuming that you find that these figures are actually reliable, would you admit that this method of inoculation appears to be of value?—Yes, I am bound to admit that—that it does appear to be of value.

13400. Now, would you turn next, please, to page 214. I want to ask you a question about rabies. Would I be right in saying that your case—as against the contention that the Pasteurian treatment of rabies is successful—is founded on the contention that Pasteur's statistics as to the mortality among untreated bitten persons are entirely fallacious?—Yes.

13401. You did not quote to us, so far as I could see, any statistics at all, but you entered into somewhat elaborate reasoning, from which you inferred what was the number of bitten persons in France in a year?—Yes.

13402. And you said that these were the largest figures available?—I think so.

13403. Will you please look at page 214?—Yes.

13404. We had this evidence presented to us relating, as you will see, to 3,127 tabulated cases of persons who were bitten by dogs reported to be rabid, and showing that the average mortality in these 3,000 odd cases was 16 per cent.?—Yes.

13405. Will you point out to the Commission where there is any probable fallacy in these figures?—Yes, I will point it out. The probable fallacy is that owing to the habit of killing the dog for fear it should bite other people, it was not then ascertained whether the dog was mad or not. Now, assuming that a dog has bitten four or five people and nobody contracts hydrophobia, the probable conclusion would be that the dog did not have hydrophobia, and those cases would be excluded from the statistics.

13406. But why? I cannot follow. Why should they be excluded? They are bitten persons?—Yes.

13407. Why should they be excluded?—Owing to the comparative rareness, and the fact that these cases are scattered about, you would have selected cases there where there was a very strong belief that the dog was mad, or some reason of that kind.

13408. I do not follow?——

13409. (*Mr. Ram.*) Why should they be excluded?—To take a specific instance, supposing that a dog runs round and bites half-a-dozen people. Somebody suspects "That dog is probably mad. Let us kill him before he bites somebody else." The dog is killed. There is a doubt about it whether the dog is mad or not. Nobody gets hydrophobia. The conclusion is that it was not a mad dog. These figures would naturally be excluded from the statistics; they would not find their way in.

13410. (*Chairman.*) But means would be taken to ascertain whether any person had got hydrophobia, and a report would be made long before that?—But so far as I know there is no evidence to show that these were made on every dog-bitten person.

13411. They profess to be?——

13412. (*Sir John McFadyean.*) I do not see how that vitiates these particular statistics. It might be that they left out a considerable number of bitten persons, but the fact would remain that there, among 3,000 persons bitten by dogs, some of which would probably be rabid (but we will assume that they were all rabid), 16 per cent. died?—Yes.

13413. Where is the fallacy in that in assuming somewhere about 16 per cent. as being the average. Because it is not a small number; it is 3,000 cases?—Taken from a great many places all over the place.

13414. But still 3,000 cases. The fact of the locality does not make it objectionable to include them in the statistics?—Not at all. But on the other hand there is a strong probability here that these were selected cases of bites.

13415. How would you select a case? Assuming that they are dogs actually rabid, in what sense could they be selected cases?—That you would get all those cases selected where the patient had hydrophobia. You get a dog that runs round and bites somebody. One of the persons gets hydrophobia. That is now certain. Those bites would be included?

13416. Yes?—If you got another case where nothing happened you would have those excluded from your statistics.

13417. But you do not discriminate between the probable danger of the bite in those two cases so far as one could see. These, after all, you will admit, will probably represent 3,000 mad dogs or 3,000 persons bitten by mad dogs?—Dogs mad and supposed to be mad.

13418. I have not been able to follow your reason why we should adopt your estimate of less than 1 per cent. when you have no precise figures to offer us at all?—Are you referring now in connection with the text book statistics?

13419. I mean this: Do these statistics on page 214 appear to indicate that out of 3,000 persons bitten by mad dogs, selected or not selected, 16 per cent. may die from rabies if they are not treated?—16 per cent., yes.

13420. They do appear to show that?—Yes.

13421. I am quite content with that?—At the same time I hope it will be recorded that I have pointed out the great fallacy in that connection.

13422. I hope that everything you said will be reported. I have no reason to suppose that it will not Will you turn next, please, to page 218. I want to call your attention to some statistics which have been put before us with regard to the efficacy of the anti-diphtheritic serum. You entertain no confidence whatever in this anti-diphtheritic serum?—None at all.

13423. You actually believe that it is a bogus claim that the diphtheria bacillus has anything to do with it?—It is not on the theory; it is on the statistics.

13424. That is your belief?—Yes.

13425. Would you explain to the Commission the extraordinarily different effect which this serum appears to have according to the period after the onset of the disease at which it is administered?—Yes.

31426. You will observe that when it is administered on the first day the mortality among persons receiving the serum appears to be, as a rule, very slight?—Quite so.

13427. But it gradually rises with the lapse of time. Will you explain the reason why?—In the first place, as regards these statistics, there is no uniformity, you notice. There is a general increase in the mortality the later the antitoxin is given. But there is no uniformity in them, which, for one thing, indicates that there is some other factor.

13428. But might the other factor be one which on *a priori* grounds would be possible, that the serum

is not always absolutely of the same strength, and we know is not always given in the same dose?—There is no reason that that should not be suggested. But I have not given my reason why these figures vary so. I merely indicate that there is some other factor besides serum, from their want of uniformity.

13429. Might I interpolate a remark there and point out that the varying factor may be in the human system?—Certainly, that is possible. That is one factor.

13430. That does not affect the value of the serum?—No. But now I had intended to point out to the Commission (but the Commission preferred it to be printed without my doing so) that there is a great fallacy in these statistics from the inclusion of selected cases; and I have here a very large amount of evidence to show that since the introduction, immediately on the introduction of the antitoxin, owing to bacteriological diagnosis, a large number of cases of mild sore throats were included as diphtheria. I think that is fairly well admitted, even by believers in the antitoxin. Now in the early stage of diphtheria there is great doubt about the diagnosis. Then in the first few days there are many mild sore throats which resemble diphtheria.

13431. Yes, I quite follow that; that among the patients treated on the first day there would be a proportion of them actually not cases of diphtheria?—Yes.

13432. But observe in some of the instances in order to make this explanation acceptable you would have to assume that none of them were cases of diphtheria. There is no mortality at all in some of the statistics among those that get the serum on the first day?—In a large number of cases?

13433. Yes, a considerable number of cases?—How large a number with no deaths on the first day? Where have you got a case of a very large number?

13434. Perhaps I was wrong in saying that there was a large number, because as a matter of fact I do not think in the particular table on page 218, which shows no mortality on the first day the figures are given, unless it relates to those above. But at any rate in the table above that the number you will see was large in some instances; there were 1,189 cases in one series, and 2,428 in another series; and in that large series there were only 2.2 on the first day?—I give two reasons for explanation. Firstly, at the earlier stage of the disease the greater is the probability of error in diagnosis, and the greater the error in diagnosis the better are the statistics. If a child has a case of sore throat, apparently on the second day it is suspected of being diphtheria, and it is given the antitoxin. The child gets well very quickly, and the result is put down to the marvellous effect of the antitoxin. But assuming that some of these cases are hospital cases you have to look for the reason—what was the reason for delay in giving the antitoxin. There must have been some reason for the delay in giving the antitoxin. The delay may have been that some doctors before giving the antitoxin would wait for the symptoms to be more marked, so as to make the diagnosis sure, while other doctors would say, "I will be on the safe side and give the antitoxin at once"; so you have great fallacies coming in for that reason. If they were hospital patients we may assume that a certain amount of delay occurred before the patient was sent to hospital; therefore you get the worst cases sent in.

13435. And you suggest to the Commission that these two sources of fallacy would account for such a difference as 2.3 mortality on the first day, and 34.1 on the sixth day?—Yes, I suggest that, but I think the Commission will be more likely to believe it after they have read what I have printed in this pamphlet.

13436. In speaking about diphtheria you quoted somebody as having said a few years ago that it was generally admitted that the Klebs-Löffler bacillus is not the cause of diphtheria. Do you want the Commission to believe that among bacteriologists and physicians that is the opinion at the present day?—I think probably not in England.*

13437. In Germany?—I do not know about Germany particularly.†

13438. France. Would I be wrong in saying that among hospital physicians and bacteriologists throughout Europe and the United States of America it is the almost universally accepted opinion that the Klebs-Löffler bacillus is the cause of diphtheria?—I could not say. I think the facts speak for themselves. I do not know the opinions of these men.

Mr. S. F. Smith, M.R.C.S.

29 Oct. 1907.

13439. You said there was something humorous about the suggestion that only those cases of disease in which the Klebs-Löffler bacillus was found should be called diphtheria?—I put it in this way: that the bacterium must always be found in the disease; that is Koch's first test. Löffler himself regarded the coincidence of clinical and bacteriological diagnosis as doubtful. This has been affirmed by others. He himself failed to find the bacillus in 25 per cent. of diphtheria cases. Hennig believed the bacterium to be absent in more than 25 per cent.

13440. I do not want to have all that over again, but what is there in the least humorous in insisting that only those cases shall now be called diphtheria in which the Klebs-Löffler bacillus is found?—I think perhaps you misunderstood me. What I said was this. We have the position humorously described by Hanseman: "The Klebs-Löffler bacillus is to be found in all cases of diphtheria, provided we select only those cases in which it is present." There is some humour in that.

13441. Nobody has ever made any such contention. Does this line of criticism apply to the present-day definition of tuberculosis, that it is the disease in which the bacillus of tuberculosis is found? Do you see anything wrong in that definition that tuberculosis is the disease in which the bacillus of tuberculosis is found?—In other words, where all the clinical symptoms exist the bacillus is found.

13442. No, on the contrary, we now know that there are a good many other disease conditions with lesions and symptoms simulating tuberculosis, but we agree to exclude them because Koch's bacillus is not found. Is it not perfectly logical in the same way to agree to exclude all cases which appear at first sight to be diphtheria, but in which the Klebs-Löffler bacillus is not found. Where is the humour in that?—The humour is in this: that bacteriologists have attempted to avoid, that is to say, deny, that these well-marked clinical cases of diphtheria are diphtheria because the bacillus is not found.

13443. In the same way that at present one contends that diseases following very closely and simulating tuberculosis are not tuberculosis if Koch's bacillus, the bacillus of tuberculosis, is not found in them. Is not that a precisely analogous case?—You are rather getting me out of my depth there, because I do not know much about tuberculosis.

13444. Surely not. I thought as you came here to criticise bacteriological work you would at least not lose your depth when I mention an elementary fact in bacteriology?—I am not criticising all bacteriology.

13445. Let us take that for granted?—I do not know anything about tuberculosis.

13446. What bacteriological disease do you know anything about. Do you believe in bacteria as the cause of disease at all?—I think one must believe it certainly, of course, in such cases as anthrax and so forth.

13447. That is good enough. We define cases of anthrax as those in which the anthrax bacillus is found, and it does not matter how like a case may be to anthrax clinically for it not to be anthrax unless the bacillus is found?—I may point out that it is a very sudden jump to suddenly exclude all these cases of clinical diphtheria because the bacillus of diphtheria is not found.

13448. (*Mr. Ram.*) Do you object to experiments upon animals if no pain results from the experiment. I am supposing the case of an experiment the object of which is to elucidate some fact which is for the benefit of humanity—an experiment which causes no pain to the animal?—I should like to say that if I thought all experiments are and would be of such a character that pain would be trivial (meaning by trivial what I call trivial and not what experimenters call trivial), I should cease to be an anti-vivisection agitator.

13449. All the evidence which you gave this morning, I think, of any examples you have seen affected only those animals which were allowed to recover?—You say I gave examples?

13450. You gave examples of animals which had

* *Lennox Browne, "Throat Diseases," 5th Edition, p. 546, says that a large number of practitioners have always denied the specificity of the bacillus, and that the number of them increases.—S.F.S.*

† *Buning in "Diptherickrankeit" quotes Lubarsch, Martins, Hennig, Hueppe, Baumgarten, Zupnik, and others.—S.F.S.*

Mr S. F. Smith, M.R.C.S.

29 Oct. 1907.

suffering inflicted upon them?—Did I? I do not remember.

13451. You gave some examples this morning in the books that you referred to. This book, for instance, which Sir William Church referred to, is full of experiments on animals which are painful?—Yes.

13452. Are you aware that under the Act with regard to cutting experiments the animals have to die under the anæsthetic except in the case of a special certificate being granted to admit of their recovery?—I am aware that there is a law to that effect—that such a law exists.

13453. Do you suggest that there are infringements of that law going on every day in England?—Yes, I do.

13454. Can you give any one instance which has come to your knowledge of an infringement of the law in England?—No, I cannot.

13455. Then on what do you justify your belief that there are many infringements of the law?—My belief is this. I do not believe that the present restrictive law has made any practical modification of vivisection at the present day although it may have modified what vivisectors have disclosed. There are two reasons for this disbelief. In the first place the inspection has been a farce. I consider that any statement to the contrary is an insult to common sense and intelligence. Secondly, obedience to a law merely because it is a law does not exist except in a small percentage of the people. Proof of that exists in the fact that nearly all people will smuggle when they can do so with safety.

13456. Do you put the case of smuggling when a man can do so with safety on precisely the same footing as that of a man of intelligence and education who is bound by law not to inflict pain upon animals or not to do so in an operation without a licence, and so forth?—I have already expressed the opinion that physiologists are mistaken about the pain which they inflict; that they are biassed in their opinion; they think the animals do not feel as they do; and that there is special reason for believing that physiologists hold an exaggerated belief of this insusceptibility of the lower animals to pain.

13457. (*Chairman.*) But would you say that the fact that a certain considerable proportion of the poor and the wretched will steal, and use the knife is a sufficient argument for you to satisfy your mind that a considerable proportion of the physiologists who are under this law break it habitually?—No, I said nothing about stealing and using the knife.

13458. You said the same sort of thing when you said that people would smuggle?—No, excuse me, there is a difference. Where a law exists concerning which the conscience is not exercised, people will not observe that law when they can break the law with impunity.

13459. (*Mr. Ram.*) Then your objections, as I understand them, are twofold, and they go to the root of all your evidence. First that pain is inflicted?—Yes.

13460. If there were no pain there would be no objection?—True.

13461. Secondly that that infliction of pain you believe goes on broadcast because the physiologist has a seared sense of sensibility?—Has blunted sensibilities.

13462. That will do. Whatever their sensibilities were the mischief could only occur in the case of animals not allowed to recover?—Or which were improperly anæsthetised during the operation.

13463. (*Chairman.*) And you say that, although these operations are never carried on in absolute solitude; there are always assistants, and in many cases spectators, and although there is no case that you know of, that you have any evidence about, yet you say it is done every day?—Yes.

13464. (*Mr. Ram.*) Have you read the evidence of the different people who have come here and said that they have operated?—I have not read all.

13465. Have you read some?—Yes.

13466. Do you observe that time after time they say that they have never witnessed any cruelty at all, or any insensibility to the sufferings of animals?—They may have done so.

13467. Do you believe their evidence?—I should disbelieve their judgment as to what pain was. Persons say there was no pain, but I have already given you examples.

13468. If it comes to be a question as many have said, that they have never known an operation performed on any animal that was inadequately anæsthetised, that is a question of fact. Do you disbelieve the assertion because the man is a vivisector?—I should say that it was not necessarily evidence, because I have already shown in evidence that there are people who believe that these movements of the animal are automatic, reflex, and that under curare they cannot tell whether the animal feels or not. I mean to say that they cannot tell whether the anæsthesia is complete.

13469. Do you deny that there are reflex actions under anæsthesia?—No, I think that does occur to a trifling extent.

13470. Then in the absence of the use of curare the animal may be fully anæsthetised and yet may make reflex motions?—I think it is very rare indeed, and I think reflex motions are very slight when they are purely reflex.

13471. (*Chairman.*) But are not these very gentlemen who perform these operations the most competent persons in England to observe reflex actions and to understand them. As to their capability you do not deny that?—I have known competent persons hold such extraordinary ideas about it.

13472. That is not answering my question. I say are not these gentlemen the most competent perhaps that can be found in England, so far as knowledge goes—the physiologists?—Yes.

13473. (*Mr. Ram.*) In regard to your own hospital do you use any antitoxins at all?—No.

13474. Any sera?—No.

13475. Have you any cases of diphtheria in your hospital?—I could not tell you about that. I have never had any cases.

13476. How long have you been connected with the hospital?—Four or five years.

13477. How long has the hospital gone on altogether?—I think I was appointed surgeon very soon after the hospital was opened.

13478. Four or five years ago?—Yes.

13479. Do you mean to say that you cannot say aye or no whether you have had any case of diphtheria or not?—No, because they would not come under my notice.

13480. What is the size of your staff?—Two surgeons, three physicians and a house surgeon.

13481. But holding the views that you do about the inutility of the diphtheritic antitoxin would it not be a matter of great interest to you to see a case treated?—With antitoxin?

13482. Either with or without?—No, I should not judge from one case for a moment.

13483. Could you find out for me whether there have been any cases of diphtheria, and what the rate of mortality has been in your hospital?—I think if they have been diagnosed at all they have not been taken in. We would not take them in if it could be helped.

13484. Why?—We have only one isolation ward. I do not think it is always furnished, and it is in a very inconvenient place.

13485. If the general view with regard to the diphtheritic antitoxin is correct it is lucky for the patients perhaps that you do not take them in?—Yes, if the view is correct that is so.

13486. With regard to your book, in this book which has been already referred to (Sir William Church has asked you about the preface) do you anywhere draw a distinction between the work done in England and the work done on the Continent?—I am afraid I could not answer that without reading the book again.

13487. Do you suggest that vivisection is carried on to-day in England just as it is carried on, or as it was carried on when you were in Strasburg?—No, because there is probably a difference in the nature of the experiments here and there to some extent. Strasburg is rather a special place for particular kinds of experiments.

13488. But you have been dealing in this book with all kinds of cruelties practised at Strasburg?—Not all kinds—some kinds.

13489. Some kinds, if you please, of cruelties practised on animals?—Yes.

13490. Were they operations of a cutting nature on animals not anæsthetised at all?—Yes.

13491. Do you suggest that that takes place in England to-day?—I do not suggest that all those experiments I mentioned there occur in England.

13492. Do you suggest that any of them do?—Yes, I suggest that it is probable, judging from human nature that the vivisector does not always take care to see that the animal is properly anæsthetised, believing as he does that the animal feels little pain.

13493. That is what you said just now. Have you any single fact upon which you can base that belief that you can bring before the Commission?—No, not a single fact.

13494. I want to read you one sentence from page 29 of your book: "My knowledge of what is done on the Continent, and my studies of the 'Journal of Physiology,' which details some of the experiments carried on in this country, prove to me absolutely that vivisection in Great Britain is not different in nature or scope to what it is on the Continent." Is that your opinion to-day?—Yes.

(*Chairman.*) Not if your last answer is correct, certainly.

(*Mr. Ram.*) I want to know whether the witness adheres to the previous or the last answer?

(*Witness.*) Would you mind reading it again?

13495. (*Mr. Ram.*) I was reading your words: "My knowledge of what is done on the Continent, and my studies of the 'Journal of Physiology,' which details some of the experiments carried on in this country, prove to me absolutely that vivisection in Great Britain is not different in nature or scope to what it is on the Continent"?—That refers largely to the nature of the experiments; that is what I had in my mind.

13496. I am asking you whether this represents your opinion of the facts to-day?—My opinion, and I am giving it simply as my opinion (I have already told you that I have no first-hand information to go upon), is that experiments of the present day do not differ from what they were at the time of the last Commission; that the present law has made no difference, and I do not believe that out of respect for the law, merely as the law and nothing more, experiments have altered.

13497. (*Chairman.*) Without having a single fact to go upon, speaking merely from what you call your knowledge of human nature, you mean to say that your opinion is that this Act has had no influence whatever upon the practice of vivisectors?—Yes.

13498. (*Mr. Ram.*) One or two questions about curare. You say, "An anæsthetised animal is immobilised by the anæsthetic. Curare in this case would be unnecessary. To speak of immobilising an anæsthetised animal would be equivalent to speaking of killing a dead animal." Is that your view now?—Yes.

13499. Have you seen the evidence given before this Commission of many cases in which, after the animal has been absolutely anæsthetised, curare has been given in order to prevent the possibility of any reflex action?—I think that the comment I put there is a fair one.

13500. You wish to stick to that, do you?—Yes.

13501. You say "it is clear that in curarised animals anæsthesia is a practical impossibility." Do you believe that?—Yes, certainly.

13502. You mean if the animal is given a lethal dose of anæsthesia?—No. If you say a lethal dose of anæsthesia, I do not say that.

13503. Then what do you mean by these words which I have just read to you "It is clear that in curarised animals anæsthesia is a practical impossibility." What does that mean?—That I am assuming, as in many of these cases, the experiment goes on for a certain length of time under chloroform and ether, and I am assuming that the experimenter does not wish the animal to die quickly, as it sometimes does when an overdose is given, and assuming that the experimenter will not give more anæsthetic than what he thinks is enough to keep the animal alive until the end of the experiment; and that inasmuch as under curare there are not the same guides which there are in giving anæsthetics on a human being, therefore it is highly probable that the animal will be conscious.

13504. Does that mean that anæsthesia is a practical impossibility in curarised animals?—Except by a lucky chance.

13505. Then you go on to speak of an animal which you saw operated on by Professors Starling and Bayliss in 1900 (I think this is an old friend), "When I first saw the animal (a small dog), he was motionless under curare." Then you go on to say what was done. Do you suggest that that dog had no anæsthetic given to it at all?—No, the account states that ether was given through a pump.

13506. Do you suggest that the dog was not anæsthetised?—I suggest that it is very highly improbable that the dog was properly anæsthetised.

13507. Then you go on to say, "This experiment is a fair example of what is going on daily throughout England"?—Yes.

13508. Do you believe that to-day?—Yes, certainly.

13509. Can you give me any fact on which you base that?—I have already shown you, I think, why it is so.

13510. I do not want deduction. I want you, if you can, to give me any case that has come to your knowledge on which you base that assertion?—I take it it is a question of statistics.

13511. Can you give me any case?—No, that is the only experiment I have seen on a living animal in England.

13512. Then why do you say it is a "fair example of what is going on daily throughout England," that being the only one that you have seen?—You have asked me the question and I think I have a right to answer it.

13513. I am trying to get you to answer it?—It is a fair example, because, firstly, I have seen, personally, cases in which curare is used, and, secondly, there are any amount of similar experiments to be found in the "Journal of Physiology."

13514. Is that the reason why you say that it is a fair example of what is going on daily?—Yes.

13515. You say on page 38, "Before the discovery of ether and chloroform, morphia was used in surgical operations. But it only diminished, it did not remove the torture." Do you still think that about morphia?—I have answered that question already.

13516. It is because you have answered it that I want to ask you a question upon it. You say now, I understand, that you have ascertained that there can be such a dose of morphia given as will produce complete anæsthesia?—Yes.

13517. Therefore you were mistaken in what you thought when you wrote this book?—I would rather say that the authorities upon which I made the statement were mistaken.

13518. At all events, you have now come to the superior knowledge that that is not correct?—Yes.

13519. Do you still believe that you are correct in saying, as you say here, that curare is used daily throughout England?—Yes.

13520. Do you believe that it is used daily throughout England on animals which are not absolutely anæsthetised?—Yes.

13521. Have you any facts on which you can base yourself for that?—Only you put in the word "daily" there.

13522. No, I have not; I am reading your words?—That is another statement, is it?

13523. Yes, it is another statement?—I have pointed out that the evidence of the "Journal of Physiology" is as to the proportion of physiological experiments in which curare is used, and I have already given you the reasons why, in my opinion, it is almost an impossibility, when you use curare, to have the animal properly anæsthetised.

13524. Do you know anybody who holds that opinion besides yourself?—I think all my colleagues do so.

13525. At the hospital?—Yes, and who belong to the Society.

13526. Eliminating those gentlemen, can you give me the name of any professional gentleman of eminence in England who holds that view?—I have not had an opportunity. My acquaintance is so limited that I could not give you any profitable information on that point.

13527. You give, in this pamphlet, certain statistics on page 67, called "Figures in favour of serum." You bring them down to 1900 only?—Yes.

13528. You have brought out another edition of this pamphlet, or brought it up to date, in which you deal with figures as late as 1904, in fact, later than that,

Mr. S. F. Smith, M.R.C.S. — 29 Oct. 1907.

because you quote the "Lancet" of 1905 on page 86?—Yes.

13529. Why was it that in those later editions, or in this bringing up to date, you did not bring these figures down to a later date than 1900?—Because I have not had the source to take them from.

13530. You have now got it before you in the evidence of Dr. Martin?—This pamphlet was printed before.

13531. But it was brought up to date later?—I have not said that I brought everything up to date. I said that some additions were made afterwards.

13532. I ask why you did not bring these figures up to date?—Because, firstly, I do not think it would have been of any interest whatever.

13533. Are you aware that if they had been brought up to date it would have shown a decrease in mortality as the use of serum was continued?—We will assume that it would have done so considerably; but I do not see the use of it.

13534. Will you answer my question. Are you aware that if you had brought your figures down from 1900 to 1905 (as you might have done), in this book, it would have shown a decreasing mortality since the use of serum became more common?—No, I am not aware of that fact.

13535. One question with regard to what you began your evidence to-day with. You said that animals probably are more sensitive to pain than other creatures because they have a keener sense of smell and hearing?—I did not say for that reason alone. I said for various reasons.

13536. You quoted the keen sense of smell?—I said that that was one part of the evidence.

13537. I see in your book that you quote an article about animals and their capacity for pain. You quote a case of a horse whose leg was broken, and you say the horse walked about on the broken bone and grazed and so forth, carrying the fractured limb dangling. You remember that case?—Yes, that is quoted.

13538. In your opinion does that show that the horse, at any rate, did not suffer very much?—I should want a good deal more evidence before believing that. It does not harmonise with all the evidence I have seen of pain in animals. Besides, even that is unauthentic.

THIRTY-FIRST DAY.

Wednesday, 30th October 1907.

PRESENT:

The Right Hon. the Viscount Selby (*Chairman*).

Sir W. S. Church, Bart., K.C.B., M.D.
Sir W. J. Collins, M.P., M.D., F.R.C.S.
Sir M. D. Chalmers, K.C.B., C.S.I.
Mr. A. J. Ram, K.C.
Mr. W. H. Gaskell, M.D., F.R.S.
Mr. J. Tomkinson, M.P.
Mr. G. Wilson, LL.D., M.D.
Captain C. Bigham, C.M.G., *Secretary*.

Mr. Francis Gotch, M.A., D.Sc., F.R.S., M.R.C.S., called in; and Examined.

Mr. F. Gotch, M.A., D.Sc., F.R.S., M.R.C.S. — 30 Oct. 1907.

13539. (*Chairman.*) You are a Doctor of Science, a Fellow of the Royal Society, and a Member of the Royal College of Surgeons, I think?—Yes.

13540. You are Waynflete Professor of Physiology in the University of Oxford?—Yes.

13541. And you come here at the request of the University?—I come here at the request of the Faculties of Medicine and Science of the University of Oxford.

13542. You are a Fellow of Magdalen College?—Yes.

13543. You yourself hold a licence, I presume, under the Act?—Yes.

13544. Have you had large experience in experimenting yourself?—I have had experience in experimenting extending now over 20 years.

13545. In research of all kinds?—In research and such experiments as I considered necessary for teaching purposes.

13546. There was a correspondence which was shown to us relating to an alleged illtreatment of a dog. Of course, I shall not omit to ask you about it, but I would rather first take you through your *précis* before I come to the correspondence?—Very good.

13547. You desire, I believe, to speak in the first place of the importance of extending physiological knowledge?—Physiology and pathology are so intimately associated, that advance in the one leads to a corresponding advance in the other; hence the undue restriction of either branch retards the progress of the other one. Medical science is based upon the existing condition of knowledge in both these subjects, since it deals with tissue processes normal and abnormal, and these are the direct subject matter of physiology and pathology. The more extensive the knowledge of these processes becomes, the more helpful will these sciences be for the prevention and mitigation of suffering in regard to both human being and domestic animals. My object in bringing forward this particular point is to enforce the fact that physiology and pathology are practically two branches of the same science, and that you cannot interfere with the one without interfering with the progress of the other; that although there may be no obvious utilitarian results from some physiological work, you cannot judge physiology on that basis.

13548. You mean that it may throw light on questions of pathology?—It may throw light on questions of pathology. I contend that you can no more separate them, for instance, than you can separate the different parts of a tree, the fruit of which is the obviously useful thing, but the physiological stem cannot be unduly interfered with without doing away with the fruit which comes from pathology. These two sciences, physiology and pathology, are under an enormous debt to physics, chemistry, and biology; this debt they partially repay by the fact that physiological and pathological discoveries and methods have in their turn helped the advance of these other sciences. The discovery of electricity, and the formulation of the law of the conservation of energy are notable instances of this. Natural science as a whole is retarded in its progress if the free development of any one of her branches is unduly restricted.

13549. (*Mr. Ram.*) Do you quote the discovery of electricity as an assistance given by physiology and pathology to chemistry and biology?—I quote it as an instance. Certain phenomena observed in animals and animal tissues led to the discovery of electricity. I may perhaps refer also to the conservation of energy. It is a very remarkable fact that this law was practically discovered by Dr. Robert Mayer in consequence of his observations on the blood of patients in Java; from these he formulated the great law which has practically determined the advance of modern physics and chemistry.

13550. (*Sir William Collins.*) Had not Joule something to do with it?—Mayer was the first formulator. I can only refer to the well-known essay on this subject by Tyndall, in which he states the history of the events quite succinctly, and puts the whole credit to Mayer.

13551. My question was, had not Joule something to do with it?—Joule certainly elaborated the question in regard to heat and its relation to various other forms of force.

13552. I thought you said that Tyndall gave the whole credit to Mayer?—The whole credit of the first formulation of the law.

13553. (*Chairman.*) Was Joule an experimenter on animals?—No.

13554. And was Mayer?—Mayer was a medical man. I could name very many other points, but I do not know whether I should name them now. One of the peculiarities I should say of physiological science is the necessity for accurately measuring time since the events occur so quickly. The accurate measurement of

time started by physiologists has been employed by engineers and has been used for measuring the muzzle velocity of projectiles. The recording arrangements employed by physiologists, first brought forward by Helmholtz and Ludwig, have been employed by engineers for obtaining graphic records of the time and working of various parts of machines. This is only an illustration of the way in which one science helps another.

13555. You mean that physiologists find it a necessity to have some very accurate method of measurement?—Yes.

13556. Who discovered the methods of so doing?—They were chiefly invented by the physiologists Helmholtz and Ludwig. Besides those branches of knowledge generally designated under the term natural science, there are others which are of great importance for the social community. Such are the study of the effect of environment on men and animals, and the study of heredity; in addition there are such scientific branches as psychology and education, this last comprising the appropriate training of both mind and body. The extension of physiological knowledge is of the utmost importance for that of the above subjects. I do not think I need dwell on that.

13557. Not unless you think it necessary. Then your next point is the methods of extending physiological knowledge?—All methods resolve themselves into two—observations on uncontrolled phenomena and observations on controlled phenomena; the control is the determining factor in what is termed experiment. Owing to the extensive scope of physiology, which comprises chemical, physical, and anatomical points of view, many of the observations of the experimental type do not necessitate the investigation of the actual living processes, at any rate, in the first instance. Others are simplified by extensive introductory study upon the isolated tissues of technically dead animals, cold-blooded or warm-blooded.

13558. What do you mean by technically dead?—The animal as such is dead, but the muscular and peripheral tissues are not dead.

13559. (*Sir Mackenzie Chalmers.*) Is the conscious life dead? Yes, the conscious life is dead, the animal being killed, and the particular organ or tissue removed from the body. But in all these cases a point is reached sooner or later when it becomes necessary to study the changes in the whole animal—that is, in one still possessing its co-ordinating mechanism. I explain co-ordinating mechanism later. I do not think I will pause to explain it now.

13560. (*Chairman.*) As you please.—This necessity must obviously exist from the first as regards the study of the co-ordinating mechanisms themselves. The co-ordinating mechanisms bring about the further co-operation or the antagonistic restraint of the activity of any one set of organs through the presence of changes in another set. Such a co-ordinating mechanism is the transfer of chemical substances by means of the circulation, and the more subtle transfer effected by means of the nervous system. For their efficient study and continued investigation experiments upon higher living animals are necessary, since in these only do the particular co-ordinating mechanisms attain a sufficient degree of development. My object in bringing this forward is to show that the scope of physiology and experiments in physiology is very large, and does not necessarily involve any experiments on living animals until you reach a certain point; but that as regards two essential things—namely, the blood as a co-ordinating mechanism and the nervous system as a co-ordinating mechanism—the very fact of co-ordination, meaning the simultaneous value of all parts, does involve experiments on the whole animal.

13561. Then your next point is the co-ordinating mechanisms of the higher animals?—In regard to the first of those, our knowledge of the circulation of the blood, of the condition by which it is modified, and of the part which is played by the character of the conveyed blood, is all due to experiments made upon living animals, and in particular upon mammals. This knowledge is still in many respects incomplete, but has been greatly advanced during the last half-century, the advance being initiated by the introduction by Ludwig of accurate recording methods. As regards the character of the conveyed blood as a determining factor in this co-ordination, there has been during the last 20 years a remarkable development through the discovery of a number of internal secretions. This discovery is entirely due to experiments on higher mammals and by demonstrating an extensive co-ordinating mechanism, which was previously unsuspected, forms a new starting-point, whose value is of the same order as that of the earlier discovery of the reflex activities of the nervous system.

Mr. F. Gotch, M.A., D.SC., F.R.S., M.R.C.S.

30 Oct. 1907

13562. When you speak of the introduction of accurate recording methods, do you mean those methods that we have heard described in the evidence—I am afraid I am not competent to describe them accurately, but when you are testing the pressure on the heart, and so forth?—Yes, the methods of recording the blood pressure, and recording the effects upon the blood pressure of various circumstances. The co-ordinating mechanism, which is termed the central nervous system, is so elaborate in higher animals that its investigation has to be conducted along many different lines. The extension of our knowledge as to the structure and processes which constitute the two main aspects of neurology has a very special importance, inasmuch as psychology, and with it scientific education (I mean an education based upon scientific principles), must be more and more based upon neurology. Much has been learnt by dissection of dead animals and by microscopic improved technique, but such fundamental principles as the distribution of functions within the different parts of the whole nervous mass, the paths by which these parts intercommunicate, and those by which they are connected with other non-nervous body structures, are all the fruit of experiments carried out on higher mammals during the last quarter of a century.

13563. I have not been asking you questions myself, because there are gentlemen here more competent than I am to ask questions on many of these points, and if they desire to do so they will do so afterwards. You now desire to speak of the necessity of a free choice of mammals for physiological research?—This choice is necessary even for the purpose of acquiring a knowledge of the gross and minute structure of tissues and organs, for which animals are painlessly killed and the dead animal then utilised. The frog and rabbit are only suitable for more general tissues, muscle, nerve, and such connective tissues as bone, cartilage, etc.; the tissues of carnivorous animals (dog, cat) must supplement the above, particularly in the case of the digestive and excretory organs; finally, the monkey's tissues must supplement the foregoing, especially in connection with the nervous system. Similar freedom of choice is demanded for the purpose of acquiring a knowledge of the process which, during life, are displayed by these structures, but in this case the study may be carried on during the stage of complete anæsthesia, thus absolutely eliminating all pain. It is, however, occasionally necessary to keep the animal alive after some particular experimental procedure has been terminated, and this is especially the case in connection with the extension of our knowledge as to the working of the co-ordinating mechanisms previously referred to. A most striking example of the great increase in knowledge brought about by experiments of this kind is that of the structure and functions of the central nervous system, as displayed by the degenerative changes and functional losses following definite nervous ablations. Here the introduction of aseptic conditions eliminates subsequent pain.

13564. With regard to the necessity of a free choice of animals, have you experimented on all these animals—the frog, the rabbit, the monkey, the dog, and the cat?—Yes, some time or other.

13565. Can you give us an instance of what you speak of as the necessity of making some experiments upon the monkey, as opposed to the dog or the cat, for example?—The question of the localisation of different functions in the cerebral hemispheres is carried out in the monkey with far greater detail than in any such animals as the dog and rabbit.

13566. If you want to discover what particular part of the brain governs the action of a particular limb or muscle or nerve?—Yes, I should certainly not accept as convincing evidence for a higher mammal any experiment except one which was on a higher mammal—that is to say, the monkey, from that point of view.

13567. Would an experiment on a dog suffice for it?—No, because the distribution of these functions in a dog is different from that in a monkey, inasmuch as the cerebral hemisphere of the dog is framed on a

Mr. F. Gotch M.A., D.SC., F.R.S., M.R.C.S. 30 Oct. 1907.

different plan. It is framed on what is termed the longitudinal plan of fissures. The transverse plan of fissures, which allows for a large nervous mass without undue protrusion forwards, is the highest type; it begins in the monkey, and goes on, of course, to man.

13568. (*Sir Mackenzie Chalmers.*) Is there an ascending scale among monkeys?—Yes.

13569. (*Chairman.*) Are experiments upon the brains of dogs or cats ever useful?—Certainly. They give useful information from the point of view of determining the action of the higher cerebral centres upon what may be termed the lower centres. The lower centres in the dog and cat, I should say, have far more effective value than in the monkey and man, for the very reason that the cerebral hemispheres themselves have not replaced them to the same extent since they are less developed.

13570. By the lower centres you mean the nerve centres?—I mean the nerve centre, including those which are at the base of the brain in what are known as the basal ganglia, the corpora striata, and the optic thalami.

13571. Then your next subject is the value of physiological experiments for physiological teaching?—Teachers of physiology hold positions of almost exceptional responsibility. In all cases they deal with a subject which forms an essential part of every medical man's intellectual equipment. In many cases, as in universities, the subject has to be also treated as a branch of natural science, and, besides medical students, there are others who approach it chiefly from this point of view. Some of these scientific students enter the teaching profession, and may have, even at present, to conduct elementary courses of physiological instruction based upon sound principles, whilst it is probable that in the future the value of enforcing the physiological principles underlying national hygiene and the physiological improvement of the young will be more and more recognised by all branches of the social community. The demand for elementary physiological knowledge will thus increase. I should like to point out that I myself have always had some students of this type, and that in some local universities these students form a considerable part. They are students who are taking up physiology with the object later on of becoming teachers.

13572. Teachers of physiology, do you mean?—Not necessarily of physiology.

13573. Some of them are teachers of science?—Teachers of science.

13574. Treating physiology as one branch of it?—Yes.

13575. But desiring to learn all?—Yes. I do not know whether the Commission is aware of the very extensive work that is done in the North in this way. Professor Sherrington has a large number of students of this type, for instance.

13576. I do not think we have had any evidence upon that point. I think we have some gentlemen coming from the northern universities. Are you referring to Manchester and Liverpool?—Yes.

13577. I think we shall have some gentlemen from there?—In all scientific teaching it is now recognised that the great desideratum is to help the student in drawing his own conclusions; this is the only real virtue of personal teaching, apart from mere book-work. This help can be afforded by personal intercourse, by lectures, and finally by enabling students to observe for themselves certain phenomena, instructing them how to control these phenomena and ascertaining that they do draw from these the legitimate conclusions. In order to accentuate this last and most convincing (practical) educational method, it is essential that the teacher should himself go through such practical work with or before his students. It is for this reason that every lecturer thus feels the necessity of illustrating his lectures by experiment; he does this not merely to display a phenomenon but to show the conditions of its control, to draw the logical conclusions himself, and make the student realise the intellectual steps by which knowledge of scientific principles has been attained. There may, however, be phenomena which, though of fundamental importance from this point of view, are difficult to control and observe; and others which for other reasons it is undesirable, even impossible, for students themselves to control and observe. The teacher has then thrust upon him an additional responsibility, since he has to determine how far he should display these phenomena, not merely for drawing conclusions, but for giving students a first-hand knowledge of their occurrence. In physiology, as in all science, teaching methods have during the last thirty years undergone a very notable change in this direction. Practical work by students in microscopic study, in physiological chemistry, and in ascertaining such features of the muscular and nervous processes as can be readily observed on the tissues of the pithed and of the dead, decerebrated frog, now forms a large part of the student's work. The extent of this work varies in different teaching institutions, but the general character is everywhere the same. There are, however, certain fundamental aspects of physiology which these practical courses, however extensive, do not display, and, as already indicated, among these aspects are those connected with the co-ordinating mechanisms. The preservation of the circulation and of the chief co-ordinated reflex activities of the animal necessitates the animal being more or less intact. But the seat of consciousness may be absolutely paralysed by anæsthetics, or destroyed by decerebration without invalidating this preservation. On fully anæsthetised animals phenomena of this character can be displayed, and the questions for the physiological teacher to settle appear to me to be four.

13578. I gather from what you said that you attach great importance to demonstration experiments on living animals accompanying lectures?—Yes.

13579. And you have fully explained your reasons for that here?—Yes.

13580. Then you come now to matters of more detail. I see you tabulate four questions that you think are involved in this question of the value of demonstrations?—Yes. I would rather put this as my personal view. I do not know that others would agree to this.

13581. We understand that this is your evidence and your opinion?—The questions for the physiological teacher to settle appear to me to be the following: (1) Is it necessary for efficient teaching of the subject to display some of these phenomena, on mammals so fully anæsthetised that no pain is possible? (2) Is it certain that such an animal can be effectually and completely anæsthetised? (3) What particular groups of phenomena should be chosen out of the whole extensive series as the most essential for students to observe? (4) What circumstances should determine the choice of animal and of anæsthetic in such demonstrations?

13582. Then you proceed to give the answers?—In answer to the first question I, personally, have no doubt of this necessity; whilst as regards the second I am convinced by practical experience that complete insensibility can be easily produced in any mammal.

13583. You have, of course, told us that you have had an experience of twenty years. You have had a very large experience I suppose of anæsthetising?—I have anæsthetised mammals of different sorts in large numbers, though not in such a large number of individual cases as many of my colleagues have.

13584. And you are very familiar with all the different anæsthetics or mixtures of anæsthetics that are used?—Yes.

13585. And you have formed your own conclusions by experience as to which are the best for particular operations?—Yes.

13586. I ask you this because we have had some gentlemen before us who have doubted whether complete anæsthesia can in some cases be obtained, and have very much doubted whether it is obtained in most cases, or in many cases, so I should like to ask you particularly upon that, whether your experience leads you to speak confidently on this question as to whether complete anæsthesia can always be obtained in experiments?—I should say, so far as my belief goes, that it is a certainty that it can be obtained.

13587. (*Mr. Tomkinson.*) For an unlimited time almost, at least for a great length of time?—For a very great length of time.

13588. What do you mean by a very great length of time?—I have been under a severe operation myself which lasted two and a half hours. I mean it is a question of hours.

13589. (*Chairman.*) And in your case, of course, it was part of the surgeon's duty to see that you did not get a lethal dose?—Yes.

13590. Which is not a thing it is necessary to avoid

(in fact, it is almost desirable to produce it) in the end in many operations upon animals?—Yes.

13591. I suppose the necessity of avoiding a lethal dose increases the difficulty?—I should think it does. I should think the most difficult animal to maintain in a prolonged condition of anæsthesia would be man.

13592. For that reason?—Yes.

13593. We have had a good deal of evidence and opinion as to whether you can be sure that you have produced complete anæsthesia in cases where curare is given—curare not given as an anæsthetic but for the purpose of keeping the animal still. There have been some strong opinions expressed before us that there are no means by which you can be sure that you have produced anæsthesia. Have you met with that difficulty?—I have had very little experience of curare.

13594. Have you used it?—I have assisted in its being used, but I have never used it myself on mammals. I should, however, have thought that it was easy to see whether there were any of those violent and inco-ordinated reflexes which we take to be the ordinary indications of pain, even under curare, because ordinary voluntary muscles whilst with the dose of curare used are put out of court, the involuntary muscles remain. And with pain you get inco-ordinated activities of these involuntary muscles, which very readily displays itself—which displays itself for instance in extreme alterations of blood pressure in consequence of the varying contraction of the muscles and the arterials.

13595. What is the object of using curare if you cannot prevent involuntary movement?—The object is to prevent the gross movements of the voluntary muscles and to leave the involuntary muscles free to be affected by the central nervous system. That is the object of using curare.

13596. You mean that the object is not to produce perfect stillness?—Only to produce perfect stillness of such muscles as move the limbs voluntarily, but not of the involuntary muscles which move the intestines, for instance, and other things.

13597. It would prevent the animal from blinking its eyes, I suppose?—Yes, that would be a voluntary muscular movement. But you would still have the indication of uncontrollable and inco-ordinated reflexes through the altered activity of the involuntary muscles which are unaffected by the dose used.

13598. Do you consider, then, that there would be something visible to the eye of the operator?—Yes.

13599. Something to tell him whether or not the animal was feeling pain?—I should say so in the alterations of blood pressure.

13600. You say that you have never yourself operated under such circumstances?—In earlier days I have assisted at operations under those circumstances, as a demonstrator I mean.

13601. What you are saying is rather a matter, as I understand, of what you think is the scientific probability than of your own personal experience and observation?—Yes.

13602. (*Mr. Ram.*) Does curare prevent the utterance of cries?—Yes, those being voluntary movements.

13603. (*Dr. Gaskell.*) It is a rise of the blood pressure is it not?—Yes.

13604. Owing to the contraction of the involuntary muscles and the blood vessels which would not be abolished by curare?—Yes.

13605. But it would be diminished if the animal was absolutely anæsthetised?—Yes.

13606. (*Chairman.*) And supposing you had taken the pains which, of course, ought to be taken in these cases—that is to say, extreme pains—to ascertain that you got the proper anæsthetising dose administered to the animal, and you took note of the time at which it was administered, would that convey any certainty to you?—I should say that it would. But you have, I should have thought, the additional certainty that in all experiments of this type, the experiment would be vitiated if there were these sudden and uncontrollable rises of blood pressure which would be produced under curare if the animal had a consciousness of pain. In experiments of this nature they are not produced.

13607. (*Sir Mackenzie Chalmers.*) For what class of experiments, then, is curare used?—Blood pressure—for certain blood-pressure experiments.

13608. Outside blood pressure it is unnecessary to use curare?—I think so. I do not know of any other.

13609. (*Chairman.*) Supposing you were experimenting on a limb which would very likely move in case of pain, like a leg or an arm, you would take direct physical means to keep it still you mean, or would you trust to the anæsthetic alone?—You cannot trust to the anæsthetic alone because there are reflexes from the spinal cord. Moreover, it is necessary to fix any animal, whether alive or dead, in order to make a proper dissection.

13610. I mean that when you do not give curare to animals to prevent these involuntary movements you rely on physical means taken to fix their attitude?—Yes.

13611. Then what is your answer to your third question?—The answer to the third question requires more detailed treatment. In making his selection the teacher must, I think, be influenced by a number of considerations. First, the character of the physiological principles which underlie the displayed phenomena. They should be fundamental, and such as cannot be convincingly set forth by experiments on the pithed frog or on any isolated organ of the dead animal. Such I consider to be the character of such demonstrations as the following:—The blood pressure, the working of the heart, the intrathoracic pressure and its changes during respiration, the respiratory movements, the action of such substances as raise and lower the blood pressure, the reflex control exercised by the nervous system over the circulation and the respiration; the nervous control of secretion and the digestive organs, and, finally, the localisation of reflex motor centres in special parts of the central nervous system. A further consideration is whether all these can be so displayed that a considerable group of students can observe and appreciate the significance of the phenomena. This depends very largely upon the possession of appropriate apparatus and of skill in its use. Associated with this is the circumstance that physiology offers extensive fields for work, so that one teacher is better acquainted with one mode of physiological technique than with another; thus he naturally selects those phenomena whose display involves the technique in which he is most skilled.

13612. I think at this point I ought to ask you a question about the conduct of students at lectures where there are demonstrations. Some witnesses have spoken of students habitually and frequently making a jest of the operations on the animals, and have accused them of demonstrations of hard-heartedness or cruelty as if they treated the whole matter as a jest. Have you seen anything of that sort at your lectures?—I cannot say that I have ever seen it. On the contrary, I am always impressed by the circumstance that this has been the most serious part, and is regarded as the most serious part, of practical physiological teaching.

13613. How many students would pass through your hands in the course of a year now at Oxford?—I have this year altogether about 70 working in my laboratory. I have not demonstrated to more than 15 or 20.

13614. It is not desirable to have a greater number at a demonstration?—No.

13615. They cannot follow it?—No, I think not. But teachers differ about that.

13616. (*Sir Mackenzie Chalmers.*) Are they all advanced students?—No, of two years—about 35 of each year.

13617. Do you demonstrate before all students, or only before advanced students?—I demonstrate some of these things before the first-year students and others before the second-year students.

13618. All students at Oxford now see actual demonstrations?—They all can see demonstrations.

13619. On mammals?—On mammals.

13620. On anæsthetised mammals?—Yes; the choice of the animal I have not yet referred to.

13621. (*Chairman.*) When you say that there are something like 15 students at a demonstration, there would be more at a lecture?—Yes, the lectures are attended by a variable group of between 30 and 50 first and second year students.

13622. Do you describe beforehand what the demonstration is to be?—Yes.

13623. At the lecture?—At an informal lecture or at the actual lecture

13624. Do only those who are making a special study

Mr. F. Gotch, M.A., D.SC., F.R.S., M.R.C.S.

Mr. F. Gotch, M.A., D.SC., F.R.S., M.R.C.S.

30 Oct. 1907.

of physiology for medical purposes go?—No, I make no distinction.

13625. (*Mr. Tomkinson.*) Would that apply to any undergraduate who was reading for honours or for a degree in natural science?—Only those reading for a degree in physiology. At Oxford the schools are separate.

13626. I thought that you said in reply to the last question that they all went without reference to a particular line?—But all those who come to my laboratory are taking this one subject of physiology.

13627. (*Sir Mackenzie Chalmers.*) You have 70 physiological students?—Yes. Natural science is a very large subject, with about 10 different ways of taking honours in it. Only the physiological students come to me, and most of them are medical students. I do not think out of my number there are more than four or five who are not.

13628. (*Sir William Collins.*) Would all the students attending the physiological course within the two years of their course see all the experiments that you demonstrate, whether they are medical students or others?—They can see them, they all can. They have the choice of seeing them; I do not say that they do.

13629. (*Chairman.*) But in groups of 15, I understand?—Yes.

13630. (*Sir Mackenzie Chalmers.*) That is as many as can be comfortably accommodated?—Some experiments I show to a larger group in the lecture room, say 30, where there is no doubt that the essential thing can be seen without any difficulty.

13631. (*Sir William Church.*) But your course in physiology and your lectures on physiology are open to any student in the University, whether he intends to take a degree in arts or intends to take a degree in natural science, are they not?—I do not think that is the case. The laboratory is by special rule placed under my supervision.

13632. You can exclude?—I can if I wish.

13633. Do you exclude a man from your courses of lectures who does not pledge himself to go in for science?—If an Oxford student came to me and said he wished to attend either lectures or courses of laboratory instruction, I should inquire what his reason was. Nor do I allow anybody to attend either lectures or courses of practical instruction unless he has seen me and given his reason for doing so.

13634. Then would you exclude a man who wished to become acquainted with physiology, but yet who probably wished to take his degree in arts rather than in science?—No, I should not do so provided he satisfied me that he had a serious intention.

13635. (*Sir Mackenzie Chalmers.*) A serious intention of studying your subject?—Yes.

13636. Not coming merely for curiosity?—Yes.

13637. When he attends your lectures has he not to enter his name and pay a fee?—There is no fee for attending professional lectures in the University.*

13638. (*Chairman.*) I presume as a matter of course that you would have the right, and would probably exercise it, of excluding any student in the lecture room who did not behave himself properly?—Yes, I have that right. I may add that I do get students of a different type altogether—gentlemen who ask to come specially to the last course of lectures that I give on the central nervous system. These are students of philosophy and psychology.

13639. (*Sir William Collins.*) I was going to ask you this question: you have suggested that all education should be based on neurology, have you not?—I have. I should like to add that in a special annex to my department which is now being built, special rooms are reserved for this particular subject, psychophysics, which is taken up, not only by philosophers, but by those who are qualifying for the education scheme of the University.

13640. (*Chairman.*) Are you now prepared to give the answer to your fourth question. What circumstances should determine the choice of animals and anæsthetic in demonstration?—The answer to the fourth question depends very largely on the selection made—that is, what experiments you select out of that group; but may be influenced by other more special considerations. The size of the animal is an important element in some, such as blood pressure, nervous control of secretion, etc.; the character of the animal in others, such as the localisation of cerebral motor centres. A considerable number can be shown upon large rabbits, and whenever this is possible it is, in my opinion, to be preferred. As regards the choice of an anæsthetic, I hold that the demonstration of the anæsthetising influence of chloroform and ether, singly or mixed, itself presents phenomena of the greatest practical importance to medical students. Apart from this, I am inclined to use, in my own demonstrations, which are made upon rabbits, chloral-hydrate, or urethane, which introduced some time previously in the alimentary canal in sufficient quantity causes a profound and increasingly developed anæsthesia; the animal's condition gradually passes beyond anæsthesia into painless death.

13641. I should like to ask you this question: we have had some evidence given which rather suggested that the interval between giving a lethal dose and painless death was too short for any use in operation. How is that?—That is not my experience in chloral-hydrate.

13642. How long will the animal live supposing you wish it to live under anæsthetics?—An hour and a half or two hours.

13643. Without giving it a fresh dose?—Without giving it a fresh dose.

13644. With a dose that is lethal when given and secures complete anæsthesia the animal may live an hour and a half?—Yes, or two hours.

13645. What animal are you speaking of?—A rabbit.

13646. Would a dog or cat live as long?—I have not had much experience in chloral-hydrate and in urethane. I may say I have had no experience upon dogs at all. I have had rather limited experience upon the cat.

13647. I wanted to see whether it was the case or not that a lethal dose operated almost immediately?—No, it is a prolonged stage.

13648. (*Mr. Tomkinson.*) Under those two substances?—Yes, being absorbed slowly from the alimentary canal.

13649. (*Mr. Ram.*) In your last answer you said you had had little or no experience in dogs, and on cats it is limited as to the use of urethane?—Yes.

13650. You have had a large experience of other anæsthetics?—I have had some experience, not so large as those of some of my colleagues.

13651. You have had some?—Yes.

13652. (*Sir Mackenzie Chalmers.*) Is this hour and a half with or without artificial respiration?—Without artificial respiration.

13653. It is the mere action of the poison that takes an hour and a half?—It depends upon the amount of dose, but you can give it so that it would take, I should say, two hours.

13654. (*Mr. Ram.*) And yet with perfect anæsthesia?—Yes.

13655. (*Sir Mackenzie Chalmers.*) Perfect anæsthesia throughout?—Yes, perfect anæsthesia throughout, and gradually deepening.

13656. Gradually deepening into death?—Gradually deepening into death.

13657. (*Chairman.*) There is no doubt of the perfect anæsthesia?—I have no doubt; there are no evidences of these irregular activities.

13658. (*Mr. Tomkinson.*) Would a rabbit be fastened down as rule?—When it is in this stage finally, do you mean?

13659. Yes?—You can fasten it or not, as you like. It lies perfectly flaccid. If I produced a rabbit here under chloral hydrate it would lie so.

13660. It would not kick or struggle?—No.

13661. Therefore there is no necessity to strap it down?—There is no necessity to strap it down, except for the purpose of making the necessary dissection.

---

* *The Professor of Physiology is authorised by a special statute to charge statutary fees on a given scale for Laboratory and is further authorised to charge a small University for students who commence attendance on lectures. This fee is to be applied towards meeting the expenses of the Department and do not go to the Professor; the charge is made at the beginning of the academic year and gives the Professor additional control over the admittance of students.—F. G.*

The necessity would practically be the same as in a dead animal.

13662. (*Sir Mackenzie Chalmers.*) To keep it in position, and to prevent your moving it with your own hand in the experiment?—Yes.

13663. (*Chairman.*) To keep the rabbit, for example, on its back?—Yes; it will not lie on this condition of absolute profound anæsthesia its back unless it is supported. The fact that in consequence of an ultimately lethal dose can be produced with such certainty in the rabbit, opens a further question. The demonstration method is not an ideal one as regards the students' acquisition of physiological principles. Viewed from this last standpoint, such acquisition would be greatly aided if it were possible for senior students under skilled and authorised supervision, and guarded by careful regulations, to themselves carry out on such profoundly and lethally anæsthetised animals some of the experimental procedures previously alluded to. The responsible character of medical, and particularly of surgical practice, renders it eminently desirable that this extension of existing possibilities should at least be seriously considered.

13664. Supposing you were consulted on the subject, what advice would you give as to the regulations that should limit the power of senior students to operate? Would you confine it to those who had taken a degree, and not begun to practise, or to those in the last year? —I should confine it to those who were in their last year in the university.

13665. But would you exercise any control, by examination or otherwise, to see whether they were qualified persons?—The control that I should exercise would be the control of a responsible person present.

13666. But in recommending them or in permitting them, if you had the power of permission, would you do it on the personal recommendation of the teacher? —I think so. I do not understand how one can make any other adequate selection. It is putting an extra responsibility, I confess, upon the teacher, but his burden already is a very heavy one, if he is a physiological teacher, and I do not think it is much extra burden.

13667. You would rely upon his observation and knowledge of the particular student?—Yes.

13668. I want now to ask you about this correspondence which took place. You are aware that Mr. Coleridge, in his evidence, called attention to a correspondence which he had with some undergraduate of Keble College; it is at Question 11455, and I will not read the letter, because you know it, and the Commission will remember it, but it was practically stating that that undergraduate had heard the yells of a dog at the University Museum, that he had satisfied himself that they proceeded from a dog under actual operation, and he spoke in strong language about the cruelty and the torture, "devilish practices," and so forth. That was signed by several other undergraduates, and then there was read a letter, I think, from yourself, denying that such a thing had taken place. Then Mr. Coleridge read a letter from Mr. Sharpe, the undergraduate in question, in which he in very strong language denies the truth of what you state, language probably which he did not, when he wrote it, intend to be read out to the Commission or anybody else, but thought he was writing to Mr. Coleridge only. However, it was read, and there the matter was left. Some questions were asked as to what Mr. Coleridge knew, and of course he said that he knew nothing about it personally, but that these gentlemen had given him this information, and he had no doubt that they were speaking the truth. I understand that since then this gentleman, Mr. Sharpe, has stated that he has inquired into the question, and has withdrawn the charge, and apologised for having made it?—Yes; and I should like in that connection to read two letters which I have been asked to read, in order that they may appear in the minutes. The first letter is a reprint of a published letter which appeared in the "Oxford Times" and the "Oxford Chronicle" of October 19th, 1907, from Dr. T. H. Warren, President of Magdalen College and Vice-Chancellor of the University of Oxford:—"Vivisection at the Oxford Museum. To the editor of the 'Oxford Times.'—Sir,—In your last issue you published an article with the above heading, taken from the 'Morning Leader,' which consisted largely of certain extracts taken from the evidence given by the Hon. Mr. Stephen Coleridge, before the Royal Commission on Vivisection. Mr. Coleridge quoted letters received by him from certain undergraduate members of Keble College, stating that it was within their knowledge that vivisection was being practised upon dogs in the Museum, and, further, that Dr. Francis Gotch, Professor of Physiology, when he stated that no vivisection on dogs had been carried on in the laboratory during the present year was not speaking the truth. I think it is just, alike to Professor Gotch and to the undergraduate members of Keble College who wrote or supported the letters, to say that I have had placed in my hands a complete apology by those undergraduates to Professor Gotch, a recognition by them of the correctness of Professor Gotch's statement, an explicit and unqualified withdrawal of the letters and statements sent and made by them to Mr. Coleridge, and an expression of their willingness that the fact of their apology and withdrawal should be published. I should be obliged, therefore, if you would now give the same publicity to the apology and withdrawal that you gave to the original statement.—I am, yours faithfully, T. Herbert Warren, Vice-Chancellor." The second letter is from the Rev. Walter Lock, D.D., Warden of Keble College, October 18th.—"Dear Professor Gotch,—I am very glad to find that you are satisfied with the apology which Mr. Sharpe and his friends have made to you, and with the action that the Vice-Chancellor is taking to make the apology public. And now that the matter is at an end, I should like to express my regret, and that of my colleagues, that you and the Museum authorities should have had this trouble, and that the relations between our college and the Museum, which have always been close and friendly, should have had even a momentary clouding. Mr. Sharpe and his friends are all excellent well-meaning fellows, who were actuated by a humane feeling, and honestly believed that the evidence which they were giving was true. But none of them is a science student or acquainted with the details of laboratory work, and I am afraid that they were not competent to estimate the real value of their evidence, the worst portion of which was based on a complete misunderstanding. They made some attempt to make inquiries, but the attempt was obviously inadequate, and I think that Mr. Coleridge treated them a little badly in accepting and making public the second letter without further investigations on his own part. As soon as further inquiries were made, and explanations given to them, they at once saw how their mistakes had arisen, and how impossible it was to substantiate their charges, and they have wholly withdrawn them. May I also thank you for the way in which your own patience and forbearance have contributed to reduce this matter to its true proportions, and to lead a friendly settlement of it. Pray make any use of this letter that you may think fit.—I am, yours sincerely, W. Lock."

13669. Have you Mr. Sharpe's letters that are referred to there?—They are in the hands of the Vice-Chancellor. I would rather not produce even a copy of them.

13670. I was going to say that it is entirely in your hands whether you wish them read or whether you wish simply to say that you are satisfied with his apology?—I am satisfied, but I should like to inform the Commission as to what the complete misunderstanding was.

13671. (*Mr. Tomkinson.*) Was one of those letters just read from Mr. Sharpe himself?—No.

13672. (*Chairman.*) Will you say how it arose?—The misunderstanding was one which may seem incredible, yet at the same time I know it does happen. These gentlemen imagined that dissection and vivisection were the same thing, and the evidence of the gentleman who was in for anatomy resolves itself into their having overheard a conversation between two students describing the work that they were doing for an examination in zoology involving the dissection of the rabbit; these students were not in my laboratory.

13673. (*Sir Mackenzie Chalmers.*) A dead rabbit?—Yes. That is their misunderstanding. The second point is that they heard dogs bark, and jumped to the conclusion, therefore, that it had some relation to the dogs. The third point is that they made inquiries of what they term an official. They made these inquiries by going in one Sunday morning, when they

Mr. F. Gotch, M.A., D.SC., F.R.S., F.R.C.S. 30 Oct. 1907.

Mr. F. Gotch. M.A., D.SC., F.R.S., M.R.C.S.

30 Oct. 1907.

saw a man going round with the keys of the museum, and they asked him whether animals were cut up in that place, to which he said, "Yes." Those are the three facts upon which the whole statement is based.

13674. (*Chairman.*) Is your laboratory in the museum?—My laboratory is at the back of the museum.

13675. And there is a dissecting room also, is there, in the museum for purposes of zoology?—Yes, at the back of the museum, for human anatomy, and also a zoological laboratory where animals are dissected.

13676. (*Sir Mackenzie Chalmers.*) Dead animals?—Yes.

13677. (*Chairman.*) When Mr. Sharpe wrote his letter, of course he was not writing about the dissection of a dead animal; he was writing about what he believed to be the vivisection of a dog?—Yes.

13678. Can you say (I only ask it because Mr. Tomkinson appears to have some further questions about it), was there any dog vivisected at that time?—No, there was no dog vivisected.

13679. (*Mr. Tomkinson.*) There is one question I want to ask you. It seems rather strange that these young men, all of them, say that they are perfectly acquainted with dogs, and that it was ridiculous to say that they could have mistaken the case of a dog in agony for the mere yapping of puppies. Can you explain it to us? Was there any dog persistently howling there day after day?—The puppies made a great noise. I am bound to say that there was no concealment in the matter at all. These puppies played in the yard, and the students themselves going through the museum used to play with them, and certainly they made a noise, a very considerable noise.

13680. (*Sir Mackenzie Chalmers.*) Whose puppies were they?—They were mine.

13681. (*Mr. Tomkinson.*) They were not there for physiological purposes—for experiments?—Not for experiments; but I will explain in a moment what was done with them. The puppies themselves were in the yard, which lies 160 yards from Keble College, with two buildings in between. But the yard opens on the parks, through which anybody may walk. There is no concealment of the animals in the physiological department; and any of these gentlemen could have walked through a public way into this yard, where the puppies were barking, and have seen them. But they did not.

13682. (*Chairman.*) I did not ask you any of these questions that you are being asked now, because I understood that this gentleman had stated that the whole thing was absolutely unfounded?—He has.

13683. And apologised?—Exactly; that is the state of affairs.

13684. You thought that was enough?—Yes.

13685. (*Sir William Collins.*) I think you were going to add what the puppies were there for?—Yes, I thought the Commission would like to know, and I am glad to add it, because I wish to introduce the subject later of the supply of animals. The puppies were kept in order that some of them might be killed in the lethal chamber later and the tissues used for the histological class of the present term. They were so killed. They were not all wanted, and two of them were given away, at the request of two of the students who used to play with them.

13686. (*Mr. Ram.*) With regard to the apology, did it contain a complete withdrawal of the assertions they made?—Yes.

13687. You observe, with regard to what you have just told us as to their mistaking dissection for vivisection, that in one of their letters they say: "A man in Keble, who is in for anatomy, told Mr. Heald (one of those who signed my paper) that they did cut up rabbits, and that lately they had cut up a small dog, and this had been yelling for a week." You observe that apparently the information which they received, and upon which they based their assertion, was not merely that a dog was cut up, but that the dog cut up, whether alive or dead, had been yelling for a week. Was any of that withdrawn?—The whole thing was withdrawn. I can only say that it does not say whether the dog was yelling before or after. The puppies yapped for a great deal more than a week.

(*Chairman.*) If there is any doubt about the fulness of the apology, I think the apology had better be read. I think it would be better, because here there are several suggestions that the charge might not have been withdrawn. Nothing is clearer than what the opinion of the Vice-Chancellor and the Warden is.

(*Mr. Tomkinson.*) I have a letter direct from Mr. Sharpe, which I have authority to read. I wrote a fortnight ago to ask him whether he had anything further to say. He wrote to me on the 20th, and I again wrote to him, asking him whether he was prepared to have his letter read to the Commission; and his last letter says: "By all means read my letter at the Commission. I quite realise the publicity it will receive, and I am perfectly prepared to take the consequences. I have heard indirectly from Professor Gotch, through the Warden, and it is his intention to make my full apology as public as possible. I do not in the least mind that, as, through false information, I made unjust charges against him with reference to the points I mentioned to you. I have therefore no wish to make a simpler withdrawal." I asked him whether he would like this letter to be read, or to make a simpler or more formal withdrawal. Now he authorises me to read this: "Dear Sir,—In reply to your letter of the 19th inst., I am sorry to say I have no more evidence to give. I have found that on closer investigation the facts which were told me as true—viz., that a dog and rabbits had been cut up, and had been yelling—were entirely false. I felt therefore compelled to withdraw these statements, and to apologise to Professor Gotch for my language concerning him when I heard he denied this. I offered to see Professor Gotch when I knew this, but he refused to see me. I am sorry he did so, because I think he might have given me further proofs if I was wrong in *all* my charges. I cannot possibly withdraw my statements in which I said I frequently heard the cries of dogs or animals of some kind in pain, nor that when I asked an official if vivisection was carried on he replied in the affirmative. I did not ask him, it is true, whether it was done with or without anæsthetics. But at any rate I have not yet had a sufficient explanation of the cries I heard, although, as a gentleman, I am willing to believe Professor Gotch's statement that 'no vivisection experiments have been carried on in the past year.' I shall be very glad to answer any more questions you might like to put to me, and might I ask if I may have a copy of the report of the last sitting of the Royal Commission."

(*Sir William Collins.*) Could we not have put in the actual letter sent to the Vice-Chancellor by these students, as that has been read?

13688. (*Chairman to the Witness.*) I do not know whether, after that letter has been read, you think it desirable to read their letter?—I will read the letters if they are desired; at the same time, they are in the hands of the Vice-Chancellor.

13688a. You have a copy of them, have you not?—I have. The first letter was from Mr. Geoffrey Heald. Mr. Geoffrey Heald is the person quoted by Mr. Sharpe. You will see that he is quoted at the bottom of the second letter.

13689. (*Sir Mackenzie Chalmers.*) Is he a student of anatomy?—No, none of them were students of anatomy or science students at all. Most of them, the only ones I know of, are theological students. "Dear Sir,—I have just seen a statement from the book relating to evidence given before the Royal Commission, and I find therein a statement made as follows: 'Dr. Gotch is a liar.' I entirely disassociate myself from such a discourteous remark, and hereby beg to assure you that I never lent nor gave authority for my name to be joined to those who have made such an imputation. I did hear from a student in the museum that a dog had been vivisected, and I concluded that that was the noise that I heard. But since you have informed me to the contrary, then I accept your statement that no vivisection has been performed during the past year.—Yours truly, Geoffrey Heald." I am prepared to state what the student was. I have his evidence. I am prepared to state what the student said. It was a student who was discussing the question of his examination in zoology.

13690. That is what you told us; that it was dissection and not vivisection?—Yes.

13691. On that letter you made inquiries about it?—Yes, on that letter I made inquiries. Mr. Sharpe wrote to me first: "Dear Sir,—I wish to write and apologise to you for the rude way in which I have

spoken of you recently, and which I am sorry to say has been published, a thing I never dreamed of. In my hastiness last term I said many things which I have since regretted. I hope you will accept my sincere apology, and regret that this should have happened." I did not accept that. Then he wrote again: "Dear Sir,—I have seen the Warden, and find from him that you do not regard the apology in my letter of yesterday as adequate. As this is so, I should like to state quite explicitly now (1) I am quite prepared to withdraw my letter of June, and to express my regret for having written it. I find that these points—viz., a dog and rabbits having been cut up alive—were quite untrue, but they were told me as facts. I was misinformed, and I cannot substantiate the charges which I and those who supported me honestly then believed to be true at the time. (2) I heartily apologise for having spoken as I did of yourself in my second letter, and withdraw my statement about you. It never occurred to me for one moment that that second letter would ever become public property. I knew that it might go before the Royal Commission, but did not know their evidence would be published. I will do what I can to cancel the publicity given to it by the Press without my consent by writing to Mr. Coleridge withdrawing my charge. I leave you free to make the withdrawal public in any other way that may seem fit to you.—I am, Sir, yours truly, Harold S. Sharpe. We, the undersigned, beg to corroborate this.—Arthur H. M. Peate, Cyril A. Bonser, Alfred C. C. Harvey Evans, Basil W. Truman."

13692. Whether he did communicate it to Mr. Coleridge you do not know beyond that letter—I do not know.

(*Sir Mackenzie Chalmers.*) At any rate, we have had no communication from Mr. Coleridge on the subject.

(*Witness.*) I may say that I have had no communication with Mr. Coleridge except that first letter on this subject at all from first to last.

13693. (*Chairman.*) That clears up the matter entirely, and makes it probable that what you say you learnt from some student was correct, that it was a mistake made as regards vivisection, and that what really was spoken of was dissection?—I have explicit information that that is the source of it.

13694. (*Dr. Wilson.*) There was no vivisection going on?—Not on dogs. I have another letter on the subject.

13695. (*Chairman.*) We have had so many letters that perhaps you had better read it?—This is an inquiry made by the Warden of Keble and Dr. Jackson, the Radcliffe Librarian, on behalf of the museum.

13696. I do not know whether it is worth while having this letter. It seems to me we are getting into too many letters?—I do not wish to bring it forward. It is an absolutely clear case, and can be vouched for by all the students, of course, not only in my department, but in other parts of the museum.

13697. (*Sir Mackenzie Chalmers.*) We have it on the Notes that no experiments were made on dogs at that time?—No vivisection experiments.

13698. When was the last time that a dog was operated on under anæsthetics—how long before, do you know?—I should think four years ago.*

13699. No dog had been operated on either with anæsthetics or without for four years in your laboratory?—No, not operated on. I cannot say definitely, but I do not think there has been a vivisection experiment.

13700. (*Chairman.*) Not for some time before that?—No, not for the last year and a half.

(*Mr. Ram.*) We have an absolute withdrawal of the charges that were brought before us. Need we go further?

(*Witness.*) I should like to say one thing more. The undergraduates were all freshmen in their first year, who knew nothing about science, and I consider that you cannot view them quite in the same light as you would view other people. But I cannot in the same light, I am bound to say, acquit Mr. Stephen Coleridge. He received this second letter; he never communicated it to me; he took no pains to find out whether this was or was not a true statement, and he interpreted it to mean cruelty without any inquiry.

13701. (*Mr. Ram.*) Although he had received your denial?—Although he had received my denial. Moreover, I want to point out again that the second letter which came before him was written in the sort of language which ought on its own showing to have awakened his suspicions. I note, for instance, that Mr. Coleridge himself, commenting in the "Times" on a statement of Lord Justice Moulton, given before this Commission, uses this very excellent language—this is quoted from his letter to the "Times": "Violence of language is only indicative of shallowness of thought and inaccuracy of statement." This is from one of Mr. Coleridge's own letters. It appears to me therefore that Mr. Coleridge, on his own showing, in consequence of the violence of the language of the second letter, might have suspected inaccuracy of statement. I have nothing more to say. *Mr. F. Gotch M.A., D.SC., F.R.S., M.R.C.S.* 30 Oct. 1907

(*Chairman.*) I think that closes that particular incident.

13702. (*Sir William Church.*) What would be your definition for the Commission of the term "pithed," when you speak of a pithed frog? We have had varying evidence given to us upon the point?—I always use the term for the destruction of the whole central nervous system.

13703. The spinal cord as well as the brain?—Yes, I use it in that way.

13704. Therefore in this *précis* "pithed" and "decerebrated" are not the same?—No.

13705. Do you think that there are any reasons for believing that a decerebrated animal is capable of feeling pain?—No, I think there is no evidence for it.

13706. I suppose it may be taken as an accepted fact from human anatomy, that when an injury takes place to the spinal cord, so long as it is not sufficiently high to implicate the breathing apparatus, the body is insensible to pain—the lower part of the body and all below the seat of injury?—Yes, certainly.

13707. Supposing there is a sufficient amount of pressure on the spinal cord of a man, you might say that you can have an amount of mere pressure upon the spinal cord which entirely prevents a man having any sensation below the seat of injury?—I think it is a certain fact that if the spinal cord is cut off (functionally or structurally) from the higher cerebral centres, below that point there is no sensation of pain.

13708. And do you know anything which would lead you to think that in a frog whose cerebral centres were removed the sensation of pain would remain?—No, I know of nothing. I do not wish to put before the Commission the wide question of the evolution of consciousness and pain, but all scientific evidence appears to show that this is a late acquisition, and that pain is a specific form of consciousness having a specific value like such definite forms as visual consciousness or tactile consciousness, and is related to the presence of definite structures, those structures being the cerebral hemispheres.

13709. It has been definitely put before us by a witness, if not more than one, that the view is held by some physiologists that sensation of pain remains even after destruction of the cerebral hemispheres in the lower animals—I mean in cold-blooded animals?—What physiologists, may I ask?

13710. That I cannot tell you. The evidence before us has been: a person has come here and stated that it is a moot question of physiology?—The physiology of the central nervous system, I should say, is the growth of the last thirty years. I do not know a single physiologist of the last thirty years who would make such a statement.

13711. There is one more question that I should like to ask you, and that is this: You think the head of a laboratory, or of a department which might embrace more than one laboratory, should be entirely responsible for the work which goes on there?—Yes.

13712. And therefore that the decision should be trusted to his judgment as to the standing of the men who are working in that laboratory?—Yes.

13713. That, of course, should they in any way either transgress the existing law, or even do anything which in his judgment he thought was not a fit experiment to be made, it ought to be in his power to be able to, in the first instance, represent the fact that they had gone

* *The witness subsequently wrote that after careful inquiry, he could not find any evidence of any licence in Oxford for performing vivisection on a dog with or without anæsthetics during the last five years.*

Mr. F. Gotch, M.A., D.Sc., F.R.S., M.R.C.S.

30 Oct. 1907.

outside their licence, if they had a licence from the Home Office, and in the second case to refuse that they should work any longer in his laboratory?—Certainly, that is my view. I should like to make some suggestions later as to the Act.

13714. (*Sir William Collins.*) I was going to take you upon that point myself. I do not think you told us how long you have held a licence?—I am afraid I cannot recollect. I had one before I went to Liverpool. Twenty years, I should say.

13715. And I do not think you told us what certificates, if any, you hold?—I hold only Certificate C at present.

13716. What does that enable you to do?—To give demonstrations.

13717. Have you ever held a certificate enabling you to dispense with the use of anæsthetics?—Completely, do you mean?

13718. Certificate A?—No.

13719. Can you tell us how many animals a year you use for vivisection purposes at Oxford?—I personally only give a few demonstrations. I do not use more than half a dozen.

13720. Could you give us any idea of the number of animals you have used for vivisection during the twenty years for which you have held a licence?—At one period I did a large number of vivisection experiments, so that I should think I must altogether have performed experiments upon 150 mammals.

13721. Not more than 150?—No.

13722. And you have enumerated some animals that you have employed. Was that a complete list?—Monkey, cat, dog, rabbit, mice, guinea pig, rat, frog, and fish.

13723. You have used your licence both for purposes of research as well as for purposes of teaching, I understand?—Yes.

13724. Have you encountered any restriction in obtaining a licence or certificate?—Never. I am bound to say that although I have not done so, a recommendation made by me was not accepted.

13725. In your capacity as a lecturer on physiology?—A recommendation for a certificate signed by me in my capacity as Professor of Physiology in the University.

13726. That is what I intended to say. I thought it was as a lecturer or Professor of Physiology in the University that you are yourself entitled to sign an application for a certificate?—Yes.

13727. Would you tell us what that case was?—It was a case which I considered to be a very important piece of work on the feeding of animals, and the effects produced by deprivation of food in a dog, in carnivorous animal.

13728. (*Sir Mackenzie Chalmers.*) A starving experiment?—Yes.

13729. (*Sir William Collins.*) Is that a case in which a licence was refused?—No, a certificate.

13730. Was that a case, then, in which, although the certificate had been signed, the Home Office intervened to prevent its coming into effect?—Yes.

13731. (*Dr. Gaskell.*) How many days starvation was it asked for?—Either six or seven days. I forget the particulars at this moment. I do not know that it was very definitely stated.

13732. (*Sir William Collins.*) In your *précis* you speak of the importance of extending physiological knowledge, and of the value of physiology in matters of psychology and education, this last, as you say, comprising the appropriate training of both mind and body, and you say that the extension of physiological knowledge is of the utmost importance for the above subjects. I gathered in the course of your examination that you intimated that in your opinion the science of education should be more and more placed upon a neurological basis?—Yes.

13733. Should I be right in saying that you think the study of neurology is desirable for the training of teachers?—Yes, that is my point.

13734. That teachers should undergo a course of instruction in physiology and specially in neurology?—I think they ought to know the elements.

13735. And that they should see these demonstrations to which you have alluded?—That is not involved, is it?

13736. I am anxious to elicit your opinion?—I should have no objection to their seeing demonstrations if they were serious students.

13737. You laid importance on what is commonly known as the heuristic method of study?—Yes.

13738. Should that apply to these cases of teachers investigating neurology?—I think it does, but I think they would generally go through what we may term the first university course, and would not therefore probably occupy the position of senior students.

13739. Should they not become acquainted with the functions of the central nervous system?—They would get their general acquaintance in the first part of this course, which is divided over two academic years.

13740. But is it possible to understand the training of mind and body without understanding the working of the central nervous system?—Some of the main principles of the working of the central nervous system can be grasped in the first year's course.

13741. Does that mean without any demonstration?—No, nor should I advise anybody to do it without doing experiments himself; for instance, in the tissues of the frog. They ought, at any rate, once to see some experiments involving higher reflex actions.

13742. But I want to understand. You place importance upon training in psychology and neurology for the training of teachers. Would you think it necessary for them to undergo a course of demonstration exhibiting the functions of the central nervous system?—I think it is desirable that they should see some typical instance of this reflex co-ordinating mechanism. The other parts of the neurology do not necessarily involve vivisection experiments, not the experiments themselves. They involve the results of vivisection experiments. Even practical work can be done, and different parts examined microscopically without the students themselves having to do a vivisection experiment.

13743. Did I correctly understand you to say that you think it is desirable that such students should have, at any rate, one demonstration upon the co-ordinating mechanism of the central nervous system?—They should see co-ordinating reflexes.

13744. Should that be on the higher mammals, as I understand you to suggest?—I think it should. I suggest the rabbit.

13745. Would not the monkey be preferable from that point of view?—That is an advanced part of the subject. I do not find that the monkey is an available animal, owing to the expense, except for a few advanced students.

13746. I understood you to say that you would only accept convincing evidence for conclusions respecting the higher animals from experiments performed upon higher animals?—I was alluding then to the brain.

13747. I was alluding to the brain?—But the central nervous system is not merely the brain.

13748. I have not heard anyone suggest it in this room?—But I said just now that I think these people ought really to see an example on an animal of this nervous co-ordinating mechanism. That includes the brain, the medulla, and the spinal cord, of course. They must see a control reflex. That is my view; it is only my own view, of course.

13749. Would that include a demonstration showing the localisation of cerebral functions?—No, I should not necessarily show that to students of this type.

13750. Why?—I think it is rather an advanced experiment.

13751. Superfluous for those studying psychology and methods of teaching?—No, I do not think it is superfluous, but you must recollect that the last monkey I had for histological purposes cost £2.

13752. It is a matter of economy?—Largely a matter of economical cost, and many considerations come in in connection with what one would demonstrate, it being implied, of course, that the animal is under an anæsthetic, and killed under the anæsthetics in every case.

13753. I gathered that both for your research work and for your teaching you have never had occasion to perform experiments on living animals without resort to anæsthetics?—No, I have not.

13754. Do you think it is ever necessary to do so?—I think it is absolutely necessary to do so. And that allows me to bring forward the first point I have in connection with the working of the Act.

13755. If you please?—I draw attention to the fact that in the working of the Act there is practically only one certificate, Certificate A, for all experiments which are done in which the anæsthetic is dispensed with. I know it is realised, I may be wrong, that inoculation experiments coming under this certificate are now treated in a separate class, not from the point of view of the certificate, but in the returns that are made I think they are put separately.

13756. (*Sir Mackenzie Chalmers.*) Separately from feeding experiments?—Separately from experiments dispensing with anæsthetics. At any rate, whether that is so or not, I want to draw attention to the fact that there are a very large number of most important experiments which have to be done on animals without anæsthetics, for which I suggest that there ought to be some separate category. These are the experiments of feeding and experiments such as Dr. Haldane is carrying on at this moment on change of environment, alteration in the atmospheric environment.

13757. (*Sir William Collins.*) Experiments not involving a cutting operation?—They do not involve a cutting operation. As it goes out to the public the public is liable to consider that all experiments coming under this certificate involve cutting operations, whereas I think it is the rarest thing. I cannot remember myself a case of an experiment having ever been done without an anæsthetic which has involved a cutting operation.

13758. (*Sir Mackenzie Chalmers.*) Certificate A would not be granted if the experiment involved a cutting operation—anything more than the prick of a hypodermic needle?—Exactly. But that is not sufficiently realised by the public, who imagine that all the experiments which are done of this class under this certificate are what they call cutting operations. I draw attention in the next place to the fact that I consider two of the most important sets of experiments that have to be done under this certificate are the experiments as to food and the experiments as to altered environment. Experiments as to food are being largely done now in America, and I need not point out their importance. The matter has formed the basis of discussion in the British Association Physiological Section at the yearly meeting. The whole question of the minimum diet, whether of the Army, Navy, workhouse, of any diet of any type whatever, is bound up in it. The question of the alterations which occur in the absence of food is not only a very important one from the point of view of ordinary starvation, but involves some principles of great importance for medicine. In fever you have starvation—semi-starvation, as well as a temperature, and we are not yet certain, in consequence of not having experiments sufficiently numerous on this particular head, whether the changes which are produced are produced by the temperature or are produced by want of assimilation of the food. This is a very important point.

13759. (*Sir William Collins.*) What you speak of as feeding experiments would include the starving experiments?—Yes, including the starving experiments.

13760. And would the alteration of environment include such things as drowning?—I should personally have said that that is an alteration of environment, and that experiments must be made upon it. I am aware that that has been before the Commission.

13761-2. Is there anything you wish to add in regard to modifications of the Act or the certificates?—I should like to make a remark (I do not know whether it is worth making) about Certificate D.

13763. Is that the certificate about repetition of experiments?—Yes.

13764. I think it would be very valuable if you would tell us your views about that?—I would point out, about that, that no experiment is a repetition; that every experiment is a display of a phenomenon and its interpretation by the mind of the person who experiments, and this interpretation must be one thing in one generation and another thing in another generation; and it is impossible, therefore, for one to repeat an experiment so far as the whole result is concerned.

13765-6. You mean that the personal equation of the investigators must be brought in?—I mean that scientific knowledge is a group of things which are framed by the minds of men.

Mr. F. Gotch, M.A., D.Sc., F.R.S., M.R.C.S.

30 Oct. 1907.

13767. For instance, I think that the argument which you have been developing has specially been mentioned in connection with the experiments by Sir Charles Bell on the spinal cord. It has been suggested that it is unnecessary to repeat those experiments with a view to ascertain the functions of the spinal cord with regard to the motor and sensory fibres. What do you say in regard to that?—I say in regard to that that the introduction of the aseptic method has altered completely our whole knowledge of the way to do experiments so as to limit the structural alteration to the part which appears to be involved; that the experiments which were made before the introduction of the aseptic method ought to be repeated, because the introduction of the new method involves a limitation which could not otherwise be attained.

13768. At one time there was a sharp conflict, was there not, between the evidence produced by Brown-Sequard and that produced by Sir Charles Bell with reference to the function of the spinal cord?—By the Brown-Sequard conflict I presume you refer to the crossing of the sensory paths.

13769. I refer to the suggestion that was made by Brown-Sequard, I think, and supported by G. H. Lewes, that Sir Charles Bell's views were altogether erroneous?—I think that means the crossing of the sensory paths. Brown-Sequard supported a view that the sensory path crossed in the cord.

13770. It was also, I think, in reference to the relative functions of the grey matter and the white matter in the cord?—I am afraid I do not know this particular conflict.

13771. I call attention to the fact that Lewes stated that the doctrine of Sir Charles Bell having been devotedly followed for many years, was shown to be wrong in every particular on the experiments of Brown-Sequard?—What date was that?

13772. 1858?—I have already pointed out that in the last 30 years the whole knowledge of the paths in the spinal cord has had to be entirely modified, due to the circumstance that the introduction of the aseptic method has defined more correctly the obvious lesion. I may point out that the method used is that of ablation—removing the part, and seeing what happens; but you must be certain what part you have removed.

13773. That does not answer the question as to whether there was this conflict or not. But do I rightly understand you to suggest that both must be put aside because they were before the introduction of the aseptic method?—I should think that they both had some elements of right and a considerable amount of wrong, and I should suggest myself that the final details of those who did work upon the central nervous system at a date prior to 50 years ago are more or less fallible.

13774. Would the same description apply to the work at the present time?—Well, we are none of us infallible; but, at the same time, the introduction of that method I have just described does, by its limiting more definitely the lesion, make our knowledge far more precise.

13775. We started from the question of the need or otherwise for the repetition of experiments. It has been suggested to the Commission that in certain areas of research knowledge has been so definitely ascertained that it is unnecessary to repeat by way of further vivisection some of the experiments that have been previously made. I rather gather from you that, in your opinion, no experiment is to be regarded as a repetition of another?—That is my view.

13776. Therefore, this Certificate D is superfluous, and there is really no finality to such research?—That is my view. I am bound to maintain, as a scientific man, that there is no finality in science. I am bound to maintain that attitude.

13777. Do I correctly understand you to suggest, in regard to fallibility, that you thought the earlier researches of Sir Charles Bell and Brown-Sequard stood in a different category from those which are being conducted now?—Yes.

13778. Did I rightly understand you to say that in the course of your 20 years' experience you have not had occasion to use curare on your own responsibility?—I have not used curare. I do not use it for the blood-

Mr. F. Gotch, M.A., D.Sc., F.R.S., M.R.C.S. 30 Oct. 1907.

pressure experiments that I show. I have not used it for the research experiments that I have done upon the nervous system.

13779. Did I rightly understand from you that curare, in your opinion, does not paralyse the involuntary muscles?—The involuntary mechanisms.

13780. Is its action in the case of the voluntary muscles upon the muscular fibres or upon the ends of the nerves?—I should say it is upon the ends of the nerves.

13781. And does it not so act upon the termination of the nerves in involuntary movements?—Not with the customary dose. It would with a very large dose, I suppose, but I have no evidence of it.

13782. It is a question of doses, is it?—I have no evidence of its being able to paralyse really involuntary nerve endings, even in very large doses.

13783. Is a change in blood pressure the only mode by which you can objectively determine whether the animal is conscious or suffering pain if under the influence of curare?—I suggest that that is one obvious way; there may be others. I really cannot say. I should have thought the other involuntary mechanisms, in the urinary bladder, for instance, or the intestines, might show similar changes. The reason why I suggest the circulation is because curare is used in circulation experiments, and consequently this particular fact of the condition of the blood pressure is brought prominently before the experimenters.

13784. Is there any other objective sign that you could mention to us which could be relied upon in addition to the variations in blood pressure?—I am afraid that I have not got any evidence of another one, but I should imagine, as I say, that most of the involuntary mechanisms which are largely influenced by pain would give objective signs of this type in the alimentary canal or the urinary bladder, for example.

13785. But you have no evidence of it?—I have no evidence.

13786. (*Dr. Gaskell.*) Would you not modify what you said just now with regard to involuntary mechanisms with respect to the action of curare on the heart? It does abolish that?—The heart is rather in an intermediate position. I was not including that at the moment in what I call the involuntary movements.

13787. (*Sir William Collins.*) Would you say unstriated rather than involuntary?—Yes, I would say unstriated.

13788. That leaves the heart out?—Yes.

13789. Then, in order to ascertain whether any changes were taking place in the blood pressure in a curarised animal, would it be necessary to have a manometer?—Yes.

13790. Without apparatus, then, it would not be possible to determine whether consciousness or pain were present?—No, I do not think so, but I do not really know.

13791. (*Sir Mackenzie Chalmers.*) In your evidence do you speak simply as Wayntlete Professor, or do you in any way come as representative or any body in the University?—Three of us were appointed to represent the Faculties of Medicine and of Science—Professor Osler, myself, and Dr. Haldane.

13792. We may take it that your evidence is on behalf of those Faculties?—Yes.

13793. Is Professor Osler not coming to give evidence?—I have only heard this morning that he is not.

13794. Then, may I ask, does your evidence represent also the opinion of Professor Osler?—Yes, I communicated verbally the *précis* of my evidence to Professor Osler.

13795. He is Regius Professor of Medicine at Oxford?—Yes.

13796. And as regards Dr. Haldane, I forget what he is?—Reader in Physiology.

13797. Is he coming or not?—I think that he would rather allow me to represent the views of the three of us.

13798. Then we may take your views as representative of the school at Oxford?—Yes.

13799. I want to ask you now on one further point. You yourself have medical qualifications?—Yes.

13800. Are there many physiologists now, and teachers of physiology, who are not medical men?—There is a growing number, I should say.

13801. Who make physiology, so to speak, their profession?—Yes.

13802. Do you think that there is any difficulty arising out of that? For instance, when a licence is granted by the Home Office to a medical man, you have the guarantee of his profession and his position in a great profession; but what guarantee have you of competence and humanity in granting a licence to a man who says simply "I am a physiologist"?—You have certainly a guarantee when a man is in a responsible position in a great university or in any university in this country, have you not?

13803. I want you to tell us what your opinion is?—I should say that that is a better guarantee really than the guarantee of belonging even to such a great profession as the medical profession—the guarantee of your being a responsible teacher in a university.

13804. Appointed by a great university?—By a university.

13805. Would you go further in granting licences to physiologists who were not medical men, or would you confine the licences to people who hold university appointments?—No, I think I should require additional information, but I should not exclude them if that information was given by people who would themselves accept the responsibility of giving it—people I have mentioned.

13806. The people who sign the certificates?—You might have a further guarantee if you wished—of that type, I mean.

13807. Now, taking your evidence generally, have I understood you rightly that the main advances in physiology have been within the last 25 or 30 years?—During the last 50 years there have been extraordinary advances in physiology.

13808. In your opinion would those advances have been possible without animal experimentation?—I should say that they are absolutely based upon animal experimentation.

13809. And in your opinion further advances must equally be based on further animal experimentation?—Yes.

13810. As regards experiments before students, you have told us the necessity of them from an educational point of view. We have been told by some witnesses that they have a brutalising effect on character. Have you any opinion on that point?—I do not believe it.

13811. We have been told, for instance, that witnessing surgical operations has not a brutalising effect, but that witnessing a physiological operation would have a brutalising effect, for this reason—that the object in a surgical operation is to save life, but the object in a physiological operation is merely to obtain knowledge. Have you any comment to make upon that?—I make the comment that I do not consider that a serious pursuit for the attainment of knowledge is brutalising. That would be the case with these students.

13812. You have had a large number of students through your hands. What has been the effect, in your observation, upon your own students?—I think that witnessing demonstrations, and even doing experiments themselves upon the pithed frog, are always regarded as a very serious part of a student's work.

13813. Do you think it is necessary for students to go any further in the way of experiment than operating upon a pithed frog?—Yes, I do. I have indicated that.

13814. What sort of licence would you suggest that students should have?—I should suggest that they should have a licence for carrying out experiments belonging to a certain category, which I am not prepared at present to frame, upon an animal which is presented to them in a fully anæsthetised state.

13815. You mean that the professor, or whoever is in charge of the laboratory, should be responsible that the animal is anæsthetised and in a state of complete insensibility to pain?—Yes.

13816. That the animal in that condition should be handed over to advanced students to do certain operations?—Yes, and killed.

13817. Who would be responsible that the animal was kept under anæsthesia until death?—I should have thought the students, under the control of this re-

sponsible official. I do not think that students ought to be allowed to do the experiments without his being present. That is what I mean. They should be done in the presence of a responsible official.

13818. A responsible official who understands anæsthesia?—Yes.

13819. And who would be responsible that the animal was kept under anæsthesia until death?—Yes, that is my view. I should rather limit this control to university officials holding responsible teaching positions.

13820. You mentioned Professor Sherrington's school. What number of students has he?—I could not tell you at this moment.

13821. Are they medical students or training physiologists?—He has medical students and physiologists, and I know he happens to have a considerable class of those who are taking physiology because they are subsequently going to become teachers. May I be allowed to make one more reference to the Act?

13822. Certainly?—I want to bring to the attention of the Commission the extraordinary fact that the Act applies to such a wide group of animals.

13823. Would you kindly explain what you would suggest?—I think it ought to be limited to warm-blooded animals.

13824. The Act should be limited to warm-blooded animals; that is to say, frogs and fish you think have such small sensation that you think they ought not to be included?—I think the whole evidence on general grounds is that pain is a function of the higher animals and evolved as a potent element for certain specific purposes, for producing or restraining certain activities. But that is only a view. At any rate, I maintain that it is inconsistent to penalise work upon fish and amphibia for purposes of scientific research since procedures as regards these animals are quite unpenalised for other purposes—for instance, the whole fishing industry. Then I have a note with regard to the whole question of the supply of animals. I think that is the weakest part of the present position.

13825. That is not dealt with, of course, by the Act at all?—No.

13826. What is your suggestion?—My suggestion is that animals like cats and dogs might be handed over by responsible people, on certain payment, and the only responsible people that I know of are the police authorities.

13827. You mean stray animals that have to be killed?—Condemned animals.

13828. Stray animals that are, so to speak, under sentence of death?—Yes.

13829. That they should be handed over without payment?—Sold by the police authorities for the purpose. I think that there is not merely a sentimental but a possible practical difficulty in the way in which animals of this kind have to be at present obtained In my own case I make every inquiry possible, but I take very few animals of this type at Oxford, and even when one attempts to grow them for histological purposes you see the difficulties one is landed in.

13830. But on the other hand what you mean is that about 30,000 dogs a year have to be destroyed in London alone, and that as they have to be destroyed you would rather have one of those animals than breed a puppy for the purpose?—I would certainly. That is my view. I may say, of course, that when I spoke of growing these animals I did not grow them for experimental purposes, I grew them to use them as dead material, and even then I was subjected to criticism.

13831. You suggested an amendment of Certificate A. Certificate A is only granted when no cutting operation is involved?—It is granted for inoculations.

13832. It is granted for inoculations; it is granted wherever there is nothing more severe than the prick of a hypodermic needle. How would it benefit anybody to split those up?—I do not see why all these experiments should be grouped together under this one certificate. They are all very different. This is the one certificate I should have thought in which you could make categories.

13833. What would the practical object be?—That the public would receive more ample information from the publication.

13834. It is limited to the public?—Yes.

13835. You referred to one case when I think about three years ago a certificate was refused by the Home Office, by Mr. Akers-Douglas?—Yes.

Mr. F. Gotch, M.A., D.Sc., F.R.S., M.R.C.S.

30 Oct. 1907.

13836. If I remember aright, I think he said that he could not authorise starving experiments that would last longer than three days?—Yes.

13837. In your opinion would that have vitiated the particular experiment you required?—Yes, the experiment had to go on for longer than three days.

13838. Would it have involved very severe suffering?—Different views are held about that. I should maintain that it would not.

13839. Starving experiments, of course, would come under Certificate A?—Yes.

13840. In your proposed new classification such would be feeding experiments?—Yes.

13841. Modifying food?—Yes.

13842. Then of course Certificate A does include certain kinds of experiments with food—for instance, experiments with new drugs?—I should group those in an entirely different category, as pharmacological experiments.

13843. How would you group inoculations of disease by feeding? When once you get into grouping you get into difficulties. You may inoculate disease by feeding?—They are divided at present, I understand, into physiological, pharmacological or pathological.

13844. You think there ought to be three categories?—Yes. I think there ought to be three.

13845. A 1, A 2, and A 3?—Yes. That is a suggestion merely.

13846. (*Mr. Ram.*) In the third part of the *précis* which you have given to us you say that as regards the character of the conveyed blood as a determining factor in the co-ordinating mechanisms of the higher animals there has been during the last 20 years a remarkable development through the discovery of a number of internal secretions. Have those matters been discovered entirely by experiments on animals?—Not entirely, but the most important of them have been discovered entirely by experiments on animals.

13847. Has the discovery of those internal secretions been a direct benefit to humanity?—I do not know to what extent they have been a direct benefit to humanity, but I should hold, of course, that the next sentence is an answer to that—namely, that by demonstrating an extensive co-ordinating mechanism, which was previously unsuspected, the discovery forms a new starting point, for the whole question of co-ordinating mechanisms has been practically brought forward.

13848. That is exactly what I am upon. That is the good you think that has resulted from those experiments?—Yes.

13849. And may that discovery in its application be a direct benefit to mankind in your opinion?—In the future I should have thought it was likely to be as directly useful as the discovery of the nervous system control. I may point out that one of these new mechanisms is the discovery by Professor Starling of secretion, a means of co-ordinating the mechanism of the pancreatic secretion.

13850. With regard to the use of some of the higher animals, in your experience do animals of a higher class of development experience greater pain than those of a lower class; are they more liable, do you think, to pain?—I hold the view, of course, that pain is a late evolution, therefore I am bound to say that I think they do. I think man of course is likely to experience it in the highest degree of all.

13851. But save in so far as they are affected by the use of anæsthetics, cats or dogs might experience a greater degree of pain in an operation than a rabbit or a lower animal than a rabbit?—That would be my belief.

13852. (*Sir Mackenzie Chalmers.*) A witness told us yesterday that he concluded that animals which have very sensitive smell or sight are more sensitive to pain than animals with less sensitive sight or smell. Is there any connection whatever between special senses of sight and smell and the power of feeling pain?—No, I do not think so.

13853. (*Mr. Ram.*) Can you see any connection between those two conditions at all?—No.

13854. (*Sir William Collins.*) Are sight and smell an earlier or a later development?—Earlier than pain, I should have thought; the relation, if any, is between

Mr. F. Gotch, M.A., D.Sc., F.R.S., M.R.C.S.

30 Oct. 1907.

tactile sense and consciousness of pain; but even there the relation is not really close.

13855. (*Mr. Ram.*) With regard to students, Sir Mackenzie Chalmers has asked you some of the questions that I wanted to ask you, but I have one or two that I still want to ask. You would only allow students to deal with an animal under an anæsthetic, which anæsthetic had been given and was watched by a responsible person?—That is my view.

13856. And you would not advocate operations, I understand, by a student in any case in which the animal was allowed to recover from the anæsthesia?—No, I do not think I should allow a student to do it as part of the physiological curriculum or for the mere purposes of teaching.

13857. Of education?—Of instruction. At the same time I am bound to say that I represent only my own view, and that Professor Osler does not agree with me in that; but he treats the matter from the point of view of the use of such experiments for subsequent medical and surgical practice, and he thinks that in many cases it would be necessary that the animals should recover.

13858. (*Sir Mackenzie Chalmers.*) He goes further than you?—Yes.

13859. (*Dr. Gaskell.*) He would rather advocate the John Hopkins' method of treating an animal like a patient?—Yes.

13860. (*Mr. Ram.*) At any rate, the action of the student would only, in your opinion, be desirable when the animal was under anæsthesia?—Yes, for physiological purposes.

13861. And even if Professor Osler's view prevailed and a student was allowed to deal with an animal which ultimately came from under the anæsthesia, at the time that the student was operating on the animal, the animal would be under anæsthesia?—Yes. I should like to add that I think what Professor Osler means is that this should not be physiology, but a subsequent course, as it were—an introduction to the practice of surgical treatment. I only deal with it from the point of view of physiology.

13862. Would you have the responsible person who is to superintend the student, and be present all the time the student is operating, to be a licensed person; would you limit it to that?—Yes, I should limit it to a licensed person. I should further limit it to a person holding a responsible position in a university.

13863. There would be very few of those. There would be some two or three in the university, perhaps?—Yes.

13864. In one answer that you made just now as to amendment of the Act you stated that you thought that work done for scientific purposes should not be penalised, as the Act is at present, by its being limited to cold-blooded animals. Do you regard the Act as to any extent penalising scientific work?—Experiments on fish are extremely difficult to carry out.

13865. Before I come to the question of cold-blooded animals, taking the Act as it stands at present, both with regard to cold-blooded animals or warm-blooded animals, do you regard it as penalising scientific work?—Perhaps I used the wrong word when I said "penalising." May I say restricting?

13866. The Act does restrict it, you think?—It does restrict it.

13867. Leaving out the question for the moment of warm-blooded animals and cold-blooded animals, does the Act restrict scientific work to an extent which, in your opinion, damages scientific research at all?—I think it does by its scope, not by its detail. I think this one question is rather an important one—it is too wide in its scope. I suggest that it is rather absurd that you should not be able to make any experiments for scientific purposes under the Act, at any rate, on fish. It is a very difficult thing to anæsthetise a fish.

13868. Then you would say that all animals other than warm-blooded animals should be exempt from the protection of the Act?—Yes.

13869. (*Sir Mackenzie Chalmers.*) They should come under the ordinary law of cruelty to animals?—Yes.

13870. (*Mr. Ram.*) Now with regard to warm-blooded animals, do you regard the Act as restricting scientific research?—No, I do not think it restricts it. I think it has operated well.

13871. A good deal has been said by some people who have been before us as to the desirability of making inspection more effective. Have you ever in your own experience been visited by the Inspector?—Yes, I am visited by the Inspector two or three or four times a year.

13872. Do you find his visit any nuisance to you at all?—Not in the least. I often am not there; that is because I do not know when he is coming.

13873. If it was thought to be otherwise desirable and feasible, should you, so far as you are concerned, have any objection to the Inspectors being multiplied in numbers and their visits being multiplied?—Not at all.

13874. With regard to curare, you have told us the effect of curare, and we have had evidence as to the amount of the use of it. Would you tell me, in the small number of cases, for we are told it is only small, in which curare is used, is the effect of curare so essential to the success of the operation that to forbid totally the use of curare would be a serious impediment to scientific research?—I think there are lines of inquiry in which it would be a very serious impediment. For instance, supposing you wished to ascertain the working of the nervous system, the discharge of nervous impulses from the nervous system without these nervous impulses being able to produce the movement of a muscle, under those circumstances it would be absolutely necessary somehow to block the end of the passage into the muscle.

13875. And the absence of curare would make that experiment impossible?—I do not know how it would be done in any other way.

13876. Would it be possible to limit and define those cases?—I think they could be more or less defined, but I think it would be difficult. It is difficult at any one stage of scientific knowledge to make a definition. That is my difficulty.

13877. Do you see any objection to its being enacted that there should be a special certificate for the use of curare?—No, I see no objection to that at all.

13878. One question as to starving operations. The carnivorous animals, as we know, can go without food for a very long time without dying?—Yes.

13879. Would it be possible in your opinion to allow starving experiments to extend with regard to carnivorous animals for such time as might be useful for science, and yet not so long as to cause any material pain to the animal?—I do not know that there is any material pain (that is my difficulty) after the discomfort of the first few days. I do not think the later stages, so far as all our evidence of starvation goes, even in man, are associated with material pain.

13880. Then if the animal suffered any pain, it would be in the first two or three days?—Yes, the discomfort would be at the start.

13881. (*Sir Mackenzie Chalmers.*) Did those exhibitors, those men who starved for forty days, suffer pain?—I do not know.

(*Dr. Gaskell.*) Then is it necessary to have a licence at all? The Hon. Stephen Coleridge told us that it was not.

13882. (*Mr. Ram.*) Should you feel justified in performing a starvation experiment without a licence?—No.

13883. (*Dr. Gaskell.*) Although you think there is no pain?—I think there is discomfort. I may say that I represent also the view of Dr. Haldane about his own experiments, which are in very much the same category; they are experiments upon alteration of environment, especially in compressed air, and are performed at the Lister Institute. There he has a licence, and on my asking him why, he said, "I cannot say that at the start there is not discomfort."

13884. (*Sir Mackenzie Chalmers.*) He has tried it on himself?—He has tried it on himself, and he found that there is some discomfort.

13885. Some discomfort at first?—Yes.

13886. (*Dr. Gaskell.*) You said just a minute ago that you would have no objection to a multiplication of inspectors. Would you adhere to the Hon. Stephen Coleridge's desire that an inspector should be present every time?—No, I do not think it is possible that he should be present every time, because then you could not perform even a simple demonstration to your class without waiting for his arrival. I understand the question to mean that there would be more inspectors

than there are at present, who would pay, I presume, surprise visits.

13887. Not that they should be so much multiplied as to be always present?—No.

13888. (*Mr. Ram.*) I understand that your objection would not be to the presence of the inspector, but to the inconvenience of always waiting for him?—Yes.

13889. You would not mind his being there?—No.

13890. (*Dr. Gaskell.*) Then with respect to urethane, I want to ask you a question. The Hon. Stephen Coleridge in the Bill which he proposes to bring forward, proposes to limit the anæsthetics to respirable gases. Have you much experience of urethane?—I use in my demonstrations either chloral-hydrate or urethane almost entirely.

13891. How many years ago is it since you used it?—The last two years urethane, and chloral hydrate the last four or five years.

13892. Do you consider that that is as efficient an agent for producing anæsthesia as a respirable gas?—Yes, and I prefer it because the dose being one which is derived from the absorption of the substance in the alimentary canal must go on gradually increasing to a certain point. You are not dependent, in short, upon the working of an external apparatus for maintaining your anæsthesia.

13893. With respect to the question of cold-blooded animals, do you know Harrison's experiments on cutting out portions of tadpoles and joining them together again?—I know of them.

13894. I presume that under the present condition of things those experiments would require a licence in England?—Certainly. I suppose they would require Certificate A.

13895. Still an experiment on a crayfish would not require anything of the kind?—No.

13896. In your opinion is not a crayfish a much more sensitive animal than a tadpole?—I think it has got a more complex nervous system, though I much doubt whether it has the particular sort of nervous system which involves a consciousness of pain.

13897. (*Sir William Collins.*) Is the crayfish a later or an earlier evolution?—An earlier evolution I should say.

13898. (*Dr. Gaskell.*) Do you consider that analgesia, the absence of sensation of pain, is not necessarily coincident with anæsthesia?—I consider that it is not necessarily coincident with anæsthesia.

13899. Which would you consider would come first?—Analgesia, by which I mean the absence of pain as in a large number of cases of hypnotism.

13900. (*Chairman.*) What other perceptions would survive when the analgesia came on and not yet anæsthesia? What would the other perceptions be that were left?—I think sight and hearing and touch might still be left as in the case of the hypnotic condition in which it is evident that the person sees and hears and feels and is entirely insensible to pain. There are cases of that description.

13901. (*Dr. Gaskell.*) Quite so. Have you made use of Certificate B at any time—to keep the animal alive after the operation?—Yes.

13902. Has your attention been called to the evidence of the Hon. Stephen Coleridge on this matter?—No.

13903. (*Sir William Collins.*) Do you hold Certificate B now. I thought you told me that Certificate C was the only one you held?—It is the only one I hold now. But I have held Certificate B and done a large number of experiments under it.

13904. (*Dr. Gaskell.*) I want to know what in your opinion is the meaning of the term "initial operation." The reference is at page 202, Q. 11473. The Hon. Stephen Coleridge there said, in answer to a question of mine: "My point is that under certificate B, as now worded, anæsthesia must be applied during the initial operation of opening the animal and fixing the electrodes to different nerves, or whatever it may be." Then I say that "under Certificate B the animal can be kept in that condition on the board, and allowed to recover its consciousness, and the animal can be kept there disembowelled, or whatever it may be, as long as the operator chooses, without any anæsthesia to allay its sufferings"?—That is an entire misconception, I should say, on Mr. Coleridge's part of the meaning of Certificate B. I hold, and everybody who has got Certificate B always holds, that anæsthesia must be applied during the whole period of any cutting operation.

Mr. F. Gotch, M.A., D.Sc., F.R.S., M.R.C.S.

30 Oct. 1907.

13905. What is the meaning of that period, the initial operation? Is it until the wound is sewn up, or what is it?—It is until the wound is not only sewn up, but I should say dressed.

13906. Dressed too?—Yes.

13907. That is your meaning of the initial operation?—Yes.

13908. And, so far as you are aware, is that the meaning that all physiologists give to that term?—Every physiologist that I know of gives that interpretation to that term.

13909. The only person, then, that you know of who does not give it that interpretation is the Hon. Stephen Coleridge?—Yes. I may say that it strikes me as a most extraordinary statement. I had not had my attention directed to it.

13910. As we are on Certificate B, there was a suggestion made by Lord Justice Moulton with respect to experiments that may involve pain such as those under Certificate B. That would be one class. That is on page 261. He advises that "certain men of acknowledged capacity in research, who have shown that they are not only capable of serious research, but have already done it, should have general certificates entitling them to perform such experiments, subject only to one thing, and that is that they should report fully every experiment. They are immeasurably better able to judge what is worth doing than any body of men that you could put over them. They are the people who are working at the subject itself, and they are, as a rule, men of such high position and high character in England that there can be no ground for being afraid of trusting them with this power." I should like to know whether you think that is a good suggestion and whether you agree with it?—I think it is a good suggestion and I agree with it, but I do not think we are seriously hampered by the working of the present Act except in regard to its scope.

13911. Do not you think that the difficulty of having to get a new certificate if you want to change the animal you are working on is a bit of a hamper?—It involves writing some letters, but I have never had any difficulty.

13912. Does it not involve loss of time?—Yes, it involves a little loss of time. I think there would be no objection to this any more than an objection to the present system, so far as I can see, and that it would be, on the whole, a more satisfactory method of giving the power.

13913. Then there is one other suggested alteration in the Act that I should like to have your opinion upon, and that is, whether it would not be advisable, certainly in the case of animals operated on under Certificate B, to allow them to live in some other place than the laboratory where they were operated upon, to have an outside farm place in which such animals could be kept. The present Act insists that they should be kept in the same place as has been licensed?—Of course, I think it would be an immense advantage, not only for science, but for the animals themselves.

13914. Would you strongly advocate that the Commission should report in favour of such a change as that?—I should. At the same time I should not wish it to be made necessary that you should transfer the animals.

13915. No, but that they should have power?—That it should not be permitted to put them in better hygienic surroundings seems to me to be wrong.

13916. Only one other question. You know most of the physiologists, or I might say all the physiologists in England practically. Have you any evidence whether or no they are kind-hearted men, who are fond of animals?—I think it is rather a remarkable thing that all physiologists almost are fond of animals, and most of them, so far as dogs are concerned, are particularly attached to dogs and keep them as pets.

13917. And the dogs are particularly attached, naturally, to them?—Yes.

13918. (*Mr. Tomkinson.*) You hold very strongly that any limitation of the freedom of choice of mammals or the higher living animals from experiment would be a distinct blow to the researches of science?—Yes.

Mr. F. Gotch, M.A., D.Sc., F.R.S. M.R.C.S.

30 Oct. 1907.

13919. In what order do you place the highest animals? Do you put the monkey first as being nearest to man in structure?—Yes.

13920. And on the whole you think in—whatever you call it—instinct or intellect?—No, I put the monkey as being nearest to man because the peculiarity of man is the development of the nervous system, and in the monkey the nervous system is the most highly developed; but I do not consider the monkey to be as near to man from the point of view of the digestive and excretory organs.

13921. And the dog next, I suppose?—The dog is nearer to man from the point of view of the digestive and excretory organs.

13922. Do you think it possible to draw an exact and a very marked dividing line between the highest, the most developed and most intelligent animal, and the very lowest form of human being known to us?—Yes, I could draw that distinction.

13923. Quite enough, apart from other considerations, to make experiments upon the one unthinkable and upon the other quite permissible?—Yes.

13924. What is the object of these operations for the sake of the investigation of the circulation and blood pressure? May I ask whether in those are included experiments for watching the operation of shock?—I presume that that would be one. But the object, as I understand it, is that the only means by which one organ can influence another is either by sending a message to the nervous system and so reaching it, or by the direct plan of the circulation, which, of course, passes through them all and is common to them all, by which I mean the assemblage of the whole organs. Therefore it becomes an extraordinarily important feature in an animal to extend our knowledge so far as possible of this means of intercommunication—viz., the circulation—and that of course is the object, as I understand it, of experiments upon the heart and blood pressure.

13925. But have not experiments of that kind and with that object been made over and over and over again, and is it necessary that they should be repeated?—Yes, and I have no doubt that they will be made over and over again.

13926. Is there something new to be discovered?—Something new is to be discovered almost in every succeeding year.

13927. Have you read a description of 14 cases of operations upon dogs by Dr. Crile?—No, I have not read them. I know the general character of the work, but I have not read it.

13928. You told us that the preservation of circulation was possible, even in an animal when paralysed by anæsthesia, or with the circulation absolutely destroyed by decerebration—that is, the taking out of the brain?—Yes, of the cerebral hemispheres.

13929. Can this circulation go on after the brain is taken out—that is, in some animals, I suppose?—The cerebral hemispheres—not the whole brain.

13930. Does pithing mean the severing of the spinal column?—I do not use the word pithing in that sense.

13931. I mean a pithed frog?—A pithed frog is one in which the whole central nervous system has been destroyed, including the spinal cord.

13932. Is the head severed from the body?—No, the whole system is destroyed in the usual way.

13933. And you are satisfied then that the frog cannot feel?—There is no central nervous system left at all then.

13934. (*Chairman.*) Is the brain taken out and the spinal cord also?—A hole is rapidly made, and by means of a wire the brain and spinal cord are destroyed with great rapidity.

13935. (*Mr. Tomkinson.*) In the case of the experiment of starvation of a dog, would water be withheld as well as food, or allowed?—In the particular experiment for which the Home Office refused a certificate water was not to be withheld. I should say that the experiment could not go on if water was withheld.

13936. In these cases of fasting by men, whether they were actually *bona fide* or not (there was some question about that, particularly in the case of Succi, whether he did not have some food), unlimited water was allowed?—Yes.

13937. Would that, in your opinion, tend to mitigate what are called the pangs of hunger?—Yes, I think so. There might be an experiment made upon the effect of withholding water, but ordinary starvation experiments must be accompanied with allowing the animal to have large amounts of water.

13938. But you rather seemed to think that the pain of starvation is negative rather than positive?—I think it may be expressed by early discomfort better than any other word.

13939. Then you think that the general opinion of the pangs of hunger and the dreadful pain of starvation is somewhat exaggerated?—I do. I think, of course, that provided you take water or something into the cavity of the stomach you will not get these particular cramps.

13940. I want to ask you one question as to the ground of your belief in the insensibility of animals, whether there is no analogy to be drawn between the sensitiveness and the development of the senses in an animal like the dog, and its application to its feeling. You admit that out of its five senses three are extremely highly developed, its sense of sight, of hearing, and scent. Everyone must admit that who knows dogs?—Yes, certainly.

13941. And as regards the fourth sense, taste, we do not know about that, but taste and smell are very close to one another, therefore we may presume almost that the dog has that fourth sense?—Yes.

13942. Then on what possible grounds are we justified in saying as we do, knowing that three at least of the senses are most highly developed, that the fifth sense, that of sensation, is duller in the dog than in man?—Do you mean by the fifth sense cutaneous sensation?

13943. I mean the power of feeling?—You mean touch.

13944. I mean the power of suffering?—Do you mean the sense of pain or the sense of touch?

13945. I put the two together?—But they are quite distinct. As I have already pointed out, the sense of pain and the sense of touch are quite distinct.

13946. But surely the sense of touch is sensitiveness?—I do not wish to go into the details, but even in a man it can be shown quite plainly that there are certain points of the skin most susceptible to contact; there are quite other points most susceptible to heat, quite other points most susceptible to cold, and quite other points most susceptible to the particular pressure which produces pain.

13947. But is it wrong to say that the five senses are seeing, hearing, smelling, tasting, feeling?—They have been greatly extended.

13948. I am afraid that the man in the street does not think so, and I am the man in the street?—I am afraid that the cutaneous sensations, as they are termed now, really comprise groups as different from one another almost as sight from hearing.

13949. The sense of touch is most highly developed in the ends of the fingers?—Yes.

13950. And surely the ends of the fingers, or the ends of the toes, are the parts of the body most sensitive to pain?—I think there are spots in your arm which could be demonstrated which would give you more pain.

13951. I would rather be vivisected in any other part of my body than in the ends of my fingers or the ends of my toes?—Then may I point out that you can touch hot things with your fingers.

13952. Only for an instant?—Without your being able to bear that temperature in other parts of your skin.

13953. Only because the skin at the end of the fingers may be a little rough or hardened by work when they have not got a covering like a glove.

13954. (*Dr. Wilson.*) I observe that you have not used dogs for two years at Oxford?—Not for vivisection experiments but for histology.

13955. As dead animals merely?—Yes.

13956. You do not believe in the necessity of demonstrating these blood pressure experiments before your class?—Yes, I demonstrate them on large rabbits, and sometimes on a cat.

13957. So that according to you—at all events, according to your experience at Oxford—dogs can be dispensed with altogether in these experiments before students?—Some things cannot be done without dogs, but then I do not do those things. I do not say that

they are not advisable to be done. For instance, the influence of the nervous system on secretion would be very difficult to do upon any other animal except a dog or a cat—preferably a dog.

13958. You do not consider it necessary for your class?—I do not do it, but I have a difficulty in the supply of animals.

13959. That is the reason, is it?—That is one reason.

13960. You say that no experiments are final?—That is my belief.

13961. The results of each experiment must be translated in a different way by different experimenters, there is that possibility always?—Yes, I should say that.

13962. So that there can be no finality?—I do not think there can be finality.

13963. And, of course, you strongly advocate experimentation on animals purely from the scientific point of view, not as an aid to medicine or surgery, or the relief of pain. You think it is absolutely essential for the acquirement of useful knowledge as a part of science?—Yes, that is, if I may say so, the trunk of my tree of knowledge. I think that physiology is in the trunk, but you cannot get the fruits, of course, if you damage the trunk. Some of these fruits are the medical and surgical advancements which result in the relief of pain. *Mr. F. Gotch, M.A., D.Sc., F.R.S. M.R.C.S.* 30 Oct. 1907.

13964. But supposing that it were even possible to prove to your satisfaction that no further cutting experiments on animals are necessary for the advancement of either medicine or surgery, you would still advocate the performance of these experiments before students?—I cannot really conceive such a condition, but I should advocate the advance of scientific knowledge under any circumstances.

13965. Would you use urethane and chloral hydrate instead of chloroform if you were experimenting with dogs?—I have had no experience of the use of urethane and chloral hydrate with dogs.

13966. Your laboratory, of course, is not very far from houses?—It is in the Parks. It is some way from houses, but still it is very open to the public.

13967. But to allay the sensibilities of the public you would recommend that laboratories for experiments on living animals should be at all events kept away from houses?—I suppose it is necessary, or at any rate desirable.

Mr. M. S. Pembrey, M.D., called in; and Examined.

13968. (*Chairman.*) You are a Doctor of Medicine and Lecturer on Physiology at Guy's Hospital?—I am. *Mr. M. S. Pembrey, M.D.*

13969. And a member of the Army Medical Advisory Board?—Yes.

13970. As a lecturer on physiology, I presume that you have had experience in experiments on living animals?—Yes, I have had considerable experience, both from the point of view of research and of teaching. I have taught physiology at Oxford, Charing Cross and Guy's.

13971. I will ask you shortly first of all a question which has been asked of many witnesses. Do you consider that the demonstration of experiments to pupils is or is not a valuable or essential part of education?—I think it is absolutely necessary if they are to obtain a proper knowledge of physiology in its application to medicine. I may take one example—coal-gas poisoning. We can show coal-gas poisoning on a mammal such as a rat or a rabbit. It takes 30 seconds to kill a rat or a rabbit with coal-gas. I can then demonstrate to the men the fact that when an animal is poisoned by coal-gas, as is perfectly well known in man, it dies a painless death—it becomes gradually unconscious, then gives convulsive movements, due to asphyxia, and dies—from lack of oxygen. If when it is dead, one cuts open the animal, one can at once demonstrate the characteristic change in the colour of the blood. Of the application of that to coal-gas poisoning we have a case in hospital at the present time. One points out to the men that the colour is quite characteristic, and the same knowledge is seen in man. And one can also show them on animals the treatment of such a case that it is no good to transfuse, as the chief thing to do is to give oxygen. Further, one can point out to them that an animal, such as a rat or a mouse, can be used as a test for the presence of carbon monoxide in the air of a mine after an explosion, and show them that by sending down an animal such as a rat or a mouse it can be used as an indicator of the presence of a poisonous quantity of the gas. This method is used. That is only one instance. Would you like me to give some further instances?

13972. If you would give us shortly one or two?—I may take another instance from experiments on the nervous system. This is one of the cases which is objected to by the anti-vivisectors. One can show upon a frog that after destruction of the cerebral hemispheres most complex movements can be carried on. The practical application of that one can bring out by showing specimens of brainless monsters. These brainless monsters, as it well known, can breathe, suck, cry and perform complicated movements, but there is no evidence of course that they are conscious.

13973. I do not quite know what a brainless monster is?—I am using the term "brainless monster" in the medical sense, that is a child born without any cerebrum. It ought not strictly to be called a child, because it is not really an individual. Then following from that example one can lead up to all the complicated mechanisms which can still act in a man who is perfectly unconscious. I could give more instances if you like, they are so many, and we use them every day. These of course are experiments which do not come strictly under the Act. Perhaps it would be well if I were to give an experiment which comes strictly under the Act, an experiment in which it is necessary to give an anæsthetic. I think it is necessary to do some experiments upon an animal under anæsthetics in order to demonstrate fundamental points on the circulation and respiration—to show, for example, the influence of opening the pleural cavity. Medical students find it very difficult to understand the mechanism of the pulmonary ventilation unless they see these experiments; they cannot form a definite idea of the contraction of the heart and of the passage of the blood through an artery and vein unless they see these experiments upon a mammal. A frog is not big enough to show the difference in the circulation in an artery and a vein. I could give many instances, but I think it would only take up your time.

13974. These are instances of the kinds of experiments which you think are absolutely necessary?—Yes, I think they are absolutely necessary.

13975. I want now to ask you some questions with reference to a statement made by Miss Lind-af-Hageby in her book, which is referred to at Question 9354 and following questions. The statement was: "We once saw a marmot the spinal cord of which had previously been divided by the vivisector," and then the story continues. You, I believe, were acquainted with that marmot?—It was my marmot.

13976. Was it kept at Guy's Hospital?—Yes.

13977. Was this experiment at Guy's Hospital?—No, it was at the University of London, South Kensington.

13978. And you brought the marmot there on that occasion?—Yes.

13979. I ask you at once, because there seems to have been considerable dispute about it, was the spinal cord of that marmot ever divided?—No, that is absolutely untrue. I have the body of the marmot here, and if you like I can show it. Perhaps I had better do it at the end of my evidence, and then I can wash my hands.

13980. How long ago did it die?—It died in 1903, but I think this marmot ought to be thoroughly well examined.

13981. Has it been preserved?—Yes, it has been preserved.

13982. Then I think you had better show it?—Shall we leave it to the end or shall I bring it out now?

13983. I think you had better do it at once—it is rather a principal point of your evidence?—Of course it may be suggested that this is not the marmot, but my laboratory man is here, and can confirm my statement that this is the marmot. (*Exhibiting the marmot.*)

13984. (*Sir Mackenzie Chalmers.*) You know that it is

Mr. M. S. Pembrey, M.D.

30 Oct. 1907.

the same marmot?—Yes, but if my word is not good enough my laboratory man can confirm it, because that may be a point of dispute.

13985. (*Chairman.*) No, that is not the point, I think?—This is the same marmot that Professor Thane examined. We did not try to mount the specimen after Professor Thane examined it. I thought of having it macerated so as to obtain its skeleton. I can cut down on to the spinal cord and show you that it has not been divided. It is as Professor Thane examined it, absolutely intact. There has never been any operation on this marmot at all.

13986. (*Sir William Collins.*) Has the spinal cord ever been exposed?—No, there has never been any cutting operation on this marmot at all. I am perfectly willing to cut through the skin and show you that the cord is undivided. I have got my laboratory man to bring a scalpel on purpose.

13987. (*Chairman.*) No, I think the Commission do not need that?—I think, at any rate, it ought to be on record that I offered to do so.

13988. Miss Hageby says that she never saw the marmot, except on that one occasion, and from what she saw on that occasion she spoke?—Well, that is the marmot.

13989. There was some question about whether the marmot had been used for experiments?—That statement is also completely false. No experiment under the Act has been performed upon this marmot by me, nor has any experiment under the Act been performed by me upon any marmot.

13990. When you say no experiment under the Act, what do you mean exactly?—I use the term in that sense simply for this reason, that confusion has arisen because Professor Thane said that no experiment was performed except taking the temperature. Taking an animal's temperature I do not consider to be an experiment, and that is the whole point upon which the apparent conflict about Professor Thane's evidence rests. It is simply the use of the term "experiment." I told Professor Thane that no experiment under the Act had been performed. The taking of an animal's temperature is not an experiment.

13991. Was the temperature taken with a view to ascertain what was the effect of hibernation upon temperature?—Yes. Simply an ordinary thermometer put into its bowel or into its mouth.

13992. Were there any experiments of starvation?—There were certain fasting experiments, and in reference to that I sent down to the Commission some letters which appeared in the "British Medical Journal."*

13993. In the experiments on fasting, was the animal hibernating at the time?—No. I have a copy of a paper here containing an account of them. They were experiments upon the marmot during the deposition of fat. These animals can put on an enormous quantity of fat, as was shown by this paper, and in order to study it on some occasions the animal was kept in a fasting condition, and exception was taken to the one in which it fasted for 52 hours. The confusion is simply due to ignorance that hibernating animals, as is notorious, often in the summer will go into a sleepy condition, and take no food for days, because they have a large storage of fat—they can almost double their weight by putting on fat—so that it does not matter to them in the least if they go without food for a week or more. In the winter, for example, they may go without food for six months.

13994. I do not know that this question of fasting is very material. What I want to know is whether the experiment—testing the effect upon the marmot of fasting 52 hours—was a natural hibernation in the summer time, or was it that while it was lively and willing to feed it was not fed?—All the conditions are stated in the paper. The rectal temperature, the weight, and all the conditions are given in this paper† (*handing in the same*). The animal was then, of course, awake; it was not hibernating. But even when they are awake they often for days take no food. In support of my word I have references to the most recent monographs upon hibernation, and I can give you them to confirm my view.

13995. Perhaps you will just give us the reference?—As a general point, it is well known that in warm climates animals often hibernate in the summer; I will give the reference to that. *Ergebnisse der Physiologie*, third year, second part, pages 220 and 221. That is the most recent work in Germany on hibernation.

13996. The only experiment in the way of feeding, I understand, was leaving the animal without food for 52 hours on one occasion?—Yes.

13997. And something less on another?—Yes; on one occasion 52 hours and on another 42 hours. They are all given in this paper.

13998. Did the animal survive that?—Yes. They would survive, as I said just now, weeks of it in the summer, if that were done. That has been done, but not by myself.

13999. What was the object of it?—The object was to see the contrast between fasting and feeding.

14000. The contrast in what way do you mean—in the appearance of the animal or in the temperature?—In the animal's temperature and respiratory exchange. The experiment was on the gases that it gives out from its lungs and bear upon the question of the deposition of fat.

14001. (*Mr. Tomkinson.*) And the weight?—And the weight.

14002. (*Sir Mackenzie Chalmers.*) So far as you could tell, did the animal suffer or not?—It suffered absolutely no pain. I have two marmots now, and I should like, in support of my evidence, to bring up one of these marmots, or to let you have the two marmots so that someone can keep one, without your knowing which, without food for 52 hours, and then you could not tell the difference. There is an opportunity for you to make the experiment. I will provide the two marmots, and you will not be able to tell the difference unless by delicate weighing.

14003. (*Chairman.*) I think we must be content with your evidence. This is very much a by-point which happens to have cropped up?—If I may say so, I think it is frivolous, because I am willing any day to fast for 52 hours without suffering pain.

14004. You are not a marmot?—But a marmot can do it all the better.

14005. Yes, I know the marmot has the advantage of you?—Yes.

14006. You say that those are the only experiments that were performed upon this particular marmot?—No experiments under the Act were performed upon it. Those were only observations, and they are not under the Act.

14007. (*Sir Mackenzie Chalmers.*) They are not under any certificate or licence?—No.

14008. You did not consider them painful?—I did not consider that they came under the Act as painful, and therefore I did not apply for a certificate. The responsibility is thrown upon me of determining whether experiments come under the Act or not, and I think it would have been frivolous if I had applied for a certificate. I could have applied for a certificate, and have protected myself from bother, but I think it would have been frivolous to do so.

14009. (*Chairman.*) We know now that the spinal cord of this marmot has never been divided; you have produced the marmot. What was the condition of the marmot on that day of which Miss Hageby spoke?—It was in a condition of hibernation, and it was waking up. I can quite easily explain why the mistake arose as to the paraplegia. The condition of the animal was that the hind legs were quite paralysed and drawn out behind the body. Instead of the animal walking like that (*describing*), it would be drawn out thus in a condition of paraplegia. This is mentioned in one of my papers, and there is no excuse for the statement that the animal's spinal cord was cut, because I can give you references to the actual papers, in which I say that no operation had been done, and in which I also give the explanation of the paraplegia. On page 80 of this paper of mine I actually explain the paraplegia (*handing in the same*).‡

14010. (*Sir William Collins.*) When was that paper published?—In 1901, two years before that statement in "The Shambles of Science" was published.

* *May 23rd and 30th, 1903.*

† *Journal of Physiology*, 1901, *vol. xxvii., p.* 407.

‡ *Journal of Physiology*, 1901, *vol. xxvii. p.* 80.

14011. (*Chairman.*) It does not follow that it had been brought to the author's notice?—No; but she refers to these papers in the Blue-book and in the evidence too. Further, I can show by reference to the *Ergebnisse* again that the condition of paralysis of the hind legs is perfectly well known to all people who have worked at the question. I can give the reference to that if the Commission wish it.

14012. I do not think it is necessary?—It is a thing that should be known. I can give the pages—227 and 228 of the *Ergebnisse.*

14013. (*Sir William Collins.*) Are the symptoms just the same as from paralysis after division of the spinal cord?—Yes. A very interesting thing also is that as the animal wakes up this paralysis passes off, and on that very day, at the end of the demonstration, by the time that the marmot got back to Guy's there was no paraplegia at all. It is a condition that comes on each winter.

14014. (*Chairman.*) Did the marmot live for some time after that?—I gave the lecture in 1902. It lived for a year, and you see that marmot now upon which, if the Commission wish to see it, I could demonstrate in one moment that the spinal cord is uncut.

14015. (*Sir Mackenzie Chalmers.*) What did this particular marmot die of a year afterwards?—It died of an abscess in its throat. There was no experiment done. The animal got an abscess in its throat which extended to the eye, and it died. It was kept practically as a pet from 1898 to 1903. During this winter I am willing, if the Commission wish, to demonstrate the paraplegia upon two marmots which I now have at Guy's.

14016. (*Chairman.*) If our functions are extended to examining into the habits of the marmot we will avail ourselves of your offer, but at the present time I do not think it is necessary.

14017. (*Sir William Collins.*) Is that the only marmot that you had at that time?—That is the only marmot I had at that time, and I believe it was the only one that any physiologist had in England.

14018. (*Chairman.*) I think in answering those questions you have answered also some attack that was made upon you in a newspaper to which you wish to refer. I think that is sufficiently answered by what you have told me?—Yes. I would like simply to show the way in which we physiologists are misrepresented. Complaints were made that I was freezing hibernating animals by exposing them to a temperature of 10°. That complaint was made and inquiry was made about it. I was asked to supply details about it. It was an absolutely fallacious statement on the part of the anti-vivisector. It was 10° Centigrade, which is the ordinary temperature of my room in the winter. They thought it was 10° below freezing point upon the Fahrenheit scale.

14019. (*Sir William Collins.*) Has that statement been made in the Blue Book?—No, it has not. This is a copy from a letter to the "British Medical Journal."

14020. (*Chairman.*) I think we are getting rather beyond the question. We are not looking up all the statements which have been made by anti-vivisectors and then proceeding to contradict them. We are inquiring into the working of the Act?—The reason why I put it in was because they did consider these to be painful experiments.

14021. It was somebody writing in the papers that they did not consider this or that, but it is not really material; it is not an attack that has been made specially upon you with reference to any evidence that you have given or anything of the kind. Those I think are the points to which you wished to draw attention, especially as regards the marmot?—There are other points, my Lord. I wish to refer to the answer to Question 7410. That is with reference to a joint book published by me and the late Dr. Phillips: "The Physiological Action of Drugs."

14022-3. This was in MissLind-af-Hageby's evidence?—Yes. I wish to bring to the notice of the Commission that it is carefully pointed out in the preface to that book that the law relating to experiments on animals renders necessary the destruction of the animal's cerebral hemispheres. I say that to me the statement of the witness is absolutely misleading, as I carefully pointed out in the preface what was the law, that these experiments must not be performed without destruction of the cerebral hemispheres, and I contend that, so far as I can understand Miss Hageby's evidence, it maintains that we did the opposite.

14024. The statement there is that you said that (*after referring to the passage*) physiologists looked upon experiments on frogs as legitimate for students to perform?—Yes, and I point out in the preface of this book that on account of the law it is necessary in all these cases that the cerebrum should be destroyed.

14025. In frogs?—In frogs; so that Miss Hageby's evidence absolutely gives an entire misrepresentation of what we say in the preface.

14026. I do not think that is quite so. Surely an experiment on a frog with its brain taken out would come under the Act?—No, it is not under the Act. A frog with its brain removed is not under the Act, and that is carefully stated in the preface.

14027. You do not mean that the Act excepts frogs altogether?—No.

14028. Do you say (the Act does not say so in so many words) that if you perform an experiment on an animal which kills it it is not an experiment?—No; it is not an experiment under the Act, if the brain has been destroyed.

14029. If part of the experiment is killing it?—Then you cannot kill the animal in any possible way without doing an experiment.

14030. You kill the frog by pithing the brain?—By destroying the function of the brain.

14031. (*Sir William Collins.*) Is that pithing that you are speaking of?—I carefully say destruction of the cerebral hemispheres.

14032. Is that pithing?—I say that pithing is the destruction of the total central nervous system. That is the definition which I use of pithing throughout the book.

14033. Destruction of the cerebral hemispheres would not, in your opinion, be pithing?—Not in the sense in which I use the word, and not in the sense in which I teach my students. I carefully draw attention to that—that pithing is used in different senses; by some observers it is used for the complete destruction of the central nervous system, and that is the sense in which I use it.

14034. (*Chairman.*) You complain that Miss Hageby says that you have spoken of frogs as animals upon which students might operate without first stating that you had said that they should only operate after the frogs have been pithed?—Yes, after pithing the cerebrum.

14035. (*Dr. Wilson.*) After decerebration?—Yes; thank you.

14036. That is the difference?—Yes. Then there is a chapter to which I would like to refer in the "Shambles of Science" on "painless experiments." It refers to a lecture of mine, and seeing that it is full of false statements, I should like to have an opportunity of being taken right through them. It begins at page 11 of the book.

14037. (*Sir Mackenzie Chalmers.*) Which edition?—I have the first—I did not know that there was another. If there is a second edition it seems to me that it is a libel on me.

14038. We have "the fourth and revised edition"?—I have only the first one, published by Bell.

14039. (*Chairman.*) Will you refer to the passage?—I should like to be taken right through. First of all it is maintained that I inserted a pair of forceps under the skin behind the skull for a moment. That is absolutely untrue.

14040. You were the lecturer on that occasion, were you?—I was the lecturer at London University. I believe the date is wrong.

14041. That is a little material as to identifying you as the lecturer?—Yes, I raised that in connection with the question whether I could bring an action for libel. I believe the date is wrong by one day. I have not looked that point up in my pocket-book just now, and I could not swear to it.

14042. (*Dr. Wilson.*) It is immaterial?—Yes, it is immaterial here. The experiments were done by me, and Dr. Waller can support my statement. I did not insert a pair of forceps under the skin. I destroyed the cerebrum, and this is also shown later on towards the end of the chapter on page 14.

Mr. M. S. Pembrey, M.D.

30 Oct. 1907.

14043. (*Chairman.*) It does not seem to me very material whether you put a pair of forceps under the skin behind the skull for a moment. You did destroy the cerebrum?—Yes; but the inference from the statement that I inserted one point of a pair of forceps under the skin behind the skull for a moment is, to any one who knows the subject, that I made a farce of destroying the cerebrum, which I did not. Then the next point is on page 13.

14044. (*Sir Mackenzie Chalmers.*) Will you read the words first to which you object?—This is a very minor point, but it is suggested there that I thought it would be better to cover over the frog after the destruction of its brain, with a cloth. I did nothing of the kind. It is often noticed in lectures that if the animal is not covered over, whether anything has been done to the animal or not, it distracts the attention of the audience, and for that reason it is constantly covered over. When an animal is brought into the theatre, it is absolutely imperative to cover up the animal before anything is done with it, or it distracts the attention of the audience in the same way as a butterfly in church will distract the attention of the congregation. It was not thought that it would "produce disagreeable reflections in some of the audience," as is stated. Then, again, on page 13, it is said that the rabbit was placed in a freezing machine. There was no freezing machine there at all. There was only an ice chest, and a piece of ice was put into that ice chest in order to lower the temperature of the ice chest.

14045. (*Chairman.*) Do you mean by an ice chest a chest with double walls for ice?—Yes. The temperature could never be down to zero, so that the rabbit was never exposed to the cold to which it is constantly exposed in winter. As a matter of fact, the temperature was four or five degrees above freezing point. The reason for that will appear later. Then it is further stated on page 13 that after fifty-five minutes the rabbit was taken out of this freezing machine, and found to be "beyond the stage for observation." Now the actual facts about it are these; and upon this I could bring Dr. Waller and Dr. Alcock, I believe they were both there. Dr. Waller I know was there. I showed before the audience that the animal's temperature had not gone down, that I had waited too long. I took the animal's temperature before the audience, and showed that the temperature was about 37 degrees Centigrade—that it had not gone down one degree.

14046. What is that Fahrenheit?—About 99 degrees—between 98 degrees and 99 degrees.

14047. What is the normal temperature of a rabbit?—About 99 degrees. Then these references must be taken together, because it is maintained on page 14 that the rabbit was "quite conscious but frozen stiff like a piece of wood." That is absolutely false, and it is shown on the face of it. An animal frozen stiff could not have a temperature of 37 degrees; it could not jump. It is absolutely absurd; it is entirely false. The animal's temperature taken before the audience was not one degree below the normal temperature, it could not therefore be even suffering from cold. The statement is absolutely false, and is shown to be false by the statement that the animal tried to get away.

14048. (*Sir Mackenzie Chalmers.*) If I understand you aright, what you meant when you said that the animal was beyond the stage of observation was that the temperature had fallen, and had very nearly gone back to normal?—Yes.

14049. That was all that you meant?—Yes, that was the only point of it, because the reason was to show the audience the importance of paying attention to the question of cold during an operation. It is well known to surgeons that unless the temperature of the air can be kept up during an operation, the patient's temperature goes down from the influence of the anæsthetic, and he is in a worse condition for recovery. I anæsthetised the rabbit. It was, therefore, not under the Act. I exposed it to a temperature of only two or three degrees above freezing point, and constantly in winter it is exposed to 10 degrees of frost under natural conditions, or even inside a laboratory it may be exposed to actual freezing point. I forgot, owing to the lecture, to take its temperature before the anæsthesia passed off. It had gone down slightly. I did not prolong the action of cold; it was beyond the stage of observation, because I did not observe it early enough, and, of course, the observation of the temperature showing that it was 37 degrees Centigrade, showed conclusively to the audience that the animal was not even suffering from cold, and that was the important thing. It is absolutely false to suggest that that animal was even suffering from cold, much less that it was frozen stiff as a board—stiff as a piece of wood.

14050. Miss Hageby states then that you again inserted an instrument into the skull cavity of the frog, moved it round several times, after which you said, "Now the brain is thoroughly destroyed," and she says, "What, then, about the first destroying"?—It is said on the first page that I only put a pair of forceps under the skin. She contradicts herself when she says that I put it into the skull in the first case. Those two points have to be taken together.

14051. She says that you informed them that you had destroyed the brain, and that the frog could not feel pain any longer?—Yes.

14052. (*Chairman.*) What had you done?—I had destroyed the cerebrum first; it was a decerebrate animal in the first case.

14053. And in the second case?—In the second case I did the complete pithing.

14054. You mean that you destroyed the rest of the brain?—Yes. I was perfectly fair at those experiments. If you read page 15, you will see evidence of my fairness, and what I complain of is that outspoken remarks are absolutely turned against me. I said I was not licensed for that laboratory, and therefore that I could not perform vivisection experiments. I said that I did not think the laboratory was licensed for vivisection experiments, and anything, therefore, that I did would be experiments which were not under the Act, and were painless experiments. And to freeze an animal, even partly, without anæsthetics, even to let its temperature go down 10 degrees, apart from any question of freezing it as stiff as a piece of wood, would be a cruel experiment. The suggestion, I maintain, is absolutely monstrous. I think it is contradicted by the statement: "The animal springs back." The only other point is about the same animal, only enforcing the same remark. The animal was not half paralysed by the cold, its eyes were not glazed in the least, and there were no signs of terror in the animal at all.

14055. Had anything been done to the rabbit at all, except putting it into this box?—Only giving it the anæsthetic.

14056. (*Sir Mackenzie Chalmers.*) Was the animal any the worse for it afterwards?—None the worse. Can I bring out a few other points that I have notes of in reference to some of the statements given in evidence before the Commission?

14057. Certainly?—One is in reference to sulphur dioxide experiments in relation to the destruction of rats on plague ships. The reference to that is in your last volume of evidence.

14058. (*Chairman.*) I have not had any notice of any other statements, except those with regard to the marmot. I did not, in fact, know that you were going to speak about these things?—When I was asked to come, I was not told at the time that I should be expected to give a *précis* of all the points I wished to bring before the Commission, but I thought, seeing that the Commissioners did touch upon the point of the sulphur dioxide experiments in connection with the destruction of rats on plague ships, I might state that I did some of those experiments within the last year or two in conjunction with some work done by Dr. Wade, who did the chemical part. It was work done for the Local Government Board. I want to draw the Commission's attention to the different position in which I was placed as a physiologist, compared with an ordinary man. A rat catcher on the Thames could use sulphur dioxide, and could be paid for using sulphur dioxide, and he could not be interfered with for the destruction of rats in that way. It was necessary for me, a physiologist, to get a special licence, which was limited to so many rats, in order that I might do experiments on rats, with the object of finding out for the Local Government Board what was the minimum dose of sulphur dioxide necessary—that is to say, I, as a physiologist, am in a worse position than a rat-catcher. These experiments are painful experiments. I returned them as painful experiments.

14059. How does the poison operate on a rat—at once?—No, it takes some time to produce fatal symptoms.

Further, one cannot do these experiments with anæsthetics. If one does them with anæsthetics one cannot arrive at the minimum dose of sulphur dioxide which is necessary to kill the rats on board ship, and therefore one cannot tell the length of time for which the ship should be shut down in order to kill all the rats. The sulphur dioxide acts upon the eyes in the first place, and I have not the least doubt causes pain. The eyes become quite opaque from the irritant action which the sulphur dioxide produces. As I said, I returned these as painful experiments. I could see that the animal felt the irritation by its trying to wash off the offending matter. The sulphur dioxide irritates its trachea and lungs, and causes violent bronchitis, and it is chiefly in that way that death is brought about. These are the painful experiments which I have done.

14060. You were not using this sulphur dioxide on board a ship for the purpose of killing all the rats on the ship?—No, I was using it in my laboratory.

14061. You were making an experiment with a view of ascertaining what was the best method of killing a rat?—And the proper dose.

14062. That was clearly an experiment under the Act?—Yes.

14063. Then you say that you are comparing your position with a rat catcher's position?—Yes; I say that I am worse off than a rat catcher.

14064. The one is killing the animals and the other is experimenting on them; that is the difference?—Yes, but a rat-catcher can kill them by the thousand and I am limited to experimenting on only five or six. I say that the limitations of the Act are against research.

14065. Under the Act there is nothing to prevent a man shooting his pack of hounds, all of them on the same day, but if he hands one of them over to you to experiment upon, that is an experiment?—Yes.

14066. Although you may be going to kill it under anæsthetics?—Yes; but the rat catcher is not killing the rat in the most painless manner possible; it is a painful death.

14067. I think we see your point?—I wanted to mention it in order to show the necessity of painful experiments. I think that painful experiments are necessary.

14068. That, of course, is the whole question. There is no question if they are not necessary?—I mean painful experiments, as against experiments under anæsthetics.

14069. (*Sir Mackenzie Chalmers.*) You maintain that they may be necessary in certain cases?—Yes. Can I give another example?

14070. Certainly?—I have worked on the question of bleeding—on the influence of bleeding and transfusion. These are experiments that I did in Germany, where it was not necessary for me to be licensed. I did them with Dr. Gürber.

14071. (*Chairman.*) With a view to what point are you bringing this forward?—To show the necessity of experiments without anæsthetics. I want to bring out the fact that if one studies the question of bleeding or transfusion, it is impossible to give an anæsthetic. If one gives an anæsthetic, one cannot study the effect of bleeding and transfusion. It is of the utmost importance that we should know what is the effect produced upon a man by the loss of a large quantity of blood. These experiments were directed to see what would be the difference in respiration, and the rabbits were not anæsthetised at all; they were simply tied down, and they did not show any violent struggling or signs of pain. I may say that my laboratory man has brought two rabbits—I did not know whether the Commissioners would like me to show the experiment, but I would like to show one point in connection with this, which I think is overlooked—that is, that if an animal is bound down on its back it often passes into a condition of hypnotism, which I can show you if you will allow me. I could take a perfectly intact rabbit, simply put it down on its back, keep a little pressure on it for a short time, then take away the pressure, and the animal will pass into a condition of hypnotism. I have seen in Germany, when I have done these experiments without anæsthetics, that these animals, when tied down, pass into a condition comparable to hypnotism, and it is known in the case of man that operations can be done under the influence of hypnotism without the patients feeling pain.

Mr. M. S. Pembrey, M.D.

30 Oct. 1907

14072. Are you suggesting that hypnotism should be used in cases of experiments and no anæsthetics?—In some cases. I want to point out that you could dispense with anæsthetics and hypnotise the animal in this way.

14073. Would there be any advantage in using hypnotism instead of anæsthetics?—Yes, because in the case of respiration the anæsthetic diminishes the respiratory exchange by one-half. Would you like me to do the experiment? There is not the least sign of pain.

(*Chairman.*) Personally, I do not desire it. There are three members of the medical profession present who understand those things better than I do. I would like to know what they think about it.

(*Sir William Collins.*) It is not new to me.

(*Dr. Wilson.*) No, we may accept the statement.

(*Dr. Gaskell.*) Certainly.

(*Witness.*) Animals do not appear to feel pain then even without an anæsthetic, and I can give evidence of that from some of the experiments that I did in Germany.

14074. (*Chairman.*) That was your experience?—That was my experience.

14075. Using hypnotism for the purpose?—Yes. Directly after the bleeding and transfusion the animal was able to run about. It was kept warm for about two hours, because there was a certain amount of shock.

14076. Did it lie still while you operated?—Yes, the animal was tied down as well to keep it in position.

14077. Did it struggle?—It only struggled when it became unconscious from asphyxia. That is another point to which I want to draw attention—that all the evidence in man, and I could do the experiment upon a man to prove it, shows that in the first stage of asphyxia, before struggling begins, there is loss of consciousness. If students experiment upon themselves by breathing in and out of a bag so that there is a lack of oxygen, they will often become quite unconscious, and tumble down before any struggling movement takes place, and one can actually anæsthetise a man simply by producing this stage of asphyxia—from the lack of oxygen. In Java anæsthesia, for example, if one presses upon the two carotids (*describing the action*) to prevent oxygen going to the brain, the man becomes unconscious. Asphyxia is not painful; it is preceded by a condition of anæsthesia from lack of oxygen. A dentist can produce a like effect simply by making a man breathe in and out of a bag in which the oxygen is gradually diminished. Although asphyxia is constantly mentioned as a painful condition, I can demonstrate upon any objector that it is not painful.

14078. What is the precise meaning of asphyxia? We all use the term. What do you say it is precisely?—The precise meaning of asphyxia, I think, is that it is the condition brought about by the lack of oxygen in the blood, and the accumulation of carbon dioxide.

14079. That is the scientific explanation, but what is the condition that is brought about?—The condition of unconsciousness and convulsions; that is to say, in popular language, unconsciousness and convulsive movements.

14080. (*Dr. Wilson.*) Garrotting, then, you would call not a painful experiment?—Not if it be done properly. You can make the experiment upon yourself, if you press upon your two carotids; there is no danger, because directly one becomes unconscious the pressure goes. If you press upon your two carotids so as to produce asphyxia of the brain, you become unconscious; then your arms are paralysed, and you save yourself by relaxing the pressure.

14081. (*Mr. Ram.*) Do you cause the brain to be gorged with blood?—No, the brain becomes in a condition of asphyxia from the combination which I gave just now—from lack of oxygen and accumulation of carbon-dioxide.

14082. (*Dr. Wilson.*) Like charcoal poisoning?—As regards lack of oxygen, yes, but there may not be an accumulation of carbon-dioxide then.

14083. (*Dr. Gaskell.*) Does not the Japanese ju-jitsu, as they call it, put a man to sleep?—I do not know. There is only one other point that I desire to draw

Mr. M. S. Pembrey, M.D.

30 Oct. 1907.

attention to, and that is this: I think one ought to recognise that pain is not the supreme evil, as one of your witnesses maintained. Pain, I maintain, from the physiological point of view, is a protective mechanism, and the modern idea of trying to abolish all pain is absolutely absurd. It is simply, from this point of view, one of the conditions of every-day life. If we take the distribution of pain we see that pain often protects an animal from danger. There is a fractured limb. The pain brings about uncomfortable sensations, so that that limb is kept in a condition of rest, which is the most satisfactory condition for repair; or there is an injury to the abdominal cavity, when pain brings about reflex alterations of the abdominal viscera, so that the viscera do not move, and therefore puts the patient in the best condition for recovery. In the case of some abdominal wounds it was notorious in the South African War that the men who were left out all night, and left to themselves to suffer this pain, and given no anæsthetics, were the men who recovered afterwards with or without operations, while the men who were treated at once and given brandy or something to relieve the suffering, were the men who died. Pain, then, is a protective mechanism, and I maintain that we are becoming so over civilised that we run a danger in our attempts to abolish pain of doing an enormous amount of harm. Take, for example, the extent to which anæsthetics are now used in cases of midwifery, in ordinary cases of delivery.

14084. (*Chairman.*) Is this an argument to show that there is no occasion for anæsthetics?—This is an argument to show that a common sense view should be taken of this question, and that pain must be admitted. I admit that I have done painful experiments, and I am not ashamed of admitting it. They are absolutely necessary. I want to show that pain is part of the scheme of nature, and that we must recognise its existence.

14085. We know that pain and pleasure and everything else are part of the scheme of nature, but I do not know that we can have the Act amended with a view to acting on that principle. When a dentist pulls a large double tooth out, he causes a great deal of pain, but I do not know that I should call it protective. It does not protect me in any way. So that if you perform an experiment deliberately on an animal and leave out anæsthetics altogether, you perform an experiment on an animal which is a painful operation?—I say that in some cases pain is absolutely protective. I will give you an example.

14086. Supposing you proceed to perform an operation on an animal, it may be protective in one sense; it may be better for the animal—I do not know, I am sure—that it should suffer some pain if it has to have an operation. But you are not protecting it in inflicting pain upon it, you are inflicting pain upon it simply?—But the pain that it actually feels is protective.

14087. I do not think we need go into such fine points as that. Surely it is a very simple proposition that if you take a knife to an animal and cut it open you inflict pain upon it?—Yes.

14088. And if you inflict pain upon it the Act says that you must use anæsthetics?—Yes.

14089. How does your theory affect that? If everything that you say about pain being protective is true, what has it got to do with the case?—In this way. I think the Act is not really what one would expect from the point of view of common sense. If an animal is cut and there is a reflex painful effect produced which would act upon its heart, under ordinary conditions—for example, the animal has been injured by a dog and torn—some of these very mechanisms which we may shut out by an overdose of anæsthetics would be protective to the animal, if the animal was to be kept alive after the operation. Therefore I maintain that it would be wiser to allow these operations often to be done without anæsthetics.

14090. The Act only applies to experiments; it does not apply to a veterinary surgeon using the knife for the purpose of saving an animal's life. This is a question only of the infliction of pain?—I think we ought to be given a licence to cover all experiments. I think that the Act is entirely antagonistic to the advancement of physiology. If we were given a licence for all experiments there would be no more cruelty. There would be a great saving of time and no limitation of work, and there would actually be in the long run a saving of life.

14091. What do you mean by a licence for all experiments?—I mean without any conditions.

14092. With or without anæsthetics?—Yes, without any limitation at all, and without certificates.

14093. That is to say, you are to put yourselves in the condition in this country which I understand physiologists are in in some parts of Germany, where there is no limit?—I think there should be no limit; that is to say, that a recognised physiologist should be given a licence to cover all experiments.

14094. Without anæsthetics?—Without anæsthetics or with anæsthetics and without certificates.

14095. And without limitations as to length?—Without reference to any conditions at all, but that he should, of course, be subject to inspection. I would point out that the difficulty of the present situation is this: I live in the country, and I could actually reckon myself as a farmer, seeing that I have more than three acres, and I do have to give a return to the Board of Agriculture. As a farmer, if I had lambs I could castrate those lambs without any anæsthetics; it would be absurd to give them anæsthetics. I have seen castration done over and over again. At Guy's I cannot castrate one lamb without a special licence, and if I tried to get a licence to castrate a lamb without giving anæsthetics it would probably be refused. My condition, then, is this: that as a private individual, if I liked to tax my conscience, I could make experiments in the country, and I could publish those experiments as a private individual, not as experiments, but simply as observations, which I could not do in my own physiological laboratory.

14096. I think you would find it rather difficult to do it if you published it, without bringing a great deal of odium upon yourself?—If I did it simply from a commercial point of view, I believe that legally I could not be touched. And then, of course, as regards pain, one causes very much more pain in the country, even unconsciously, than one does in a physiological laboratory. The worst pain that I ever caused I am convinced—I could bring evidence in support of it, but I am quite convinced—was in a case where I took away a calf from a cow. The cow was exceedingly fond of the calf; the calf was too big, and I wanted the milk for my children, so I took away the calf and sold it. For two days that cow was in obvious pain; it would not take its food; it went about bellowing, roaring, and moaning, and was so bad that the cottagers complained. There is a case in which it was perfectly obvious to me that the animal was suffering pain for two days. Never in any physiological experiment have I caused so much pain, even under the Act, as one does every day in the country.

14097. The Act deals with physical pain?—I cannot see the difference between physical and mental pain from a physiological point of view.

14098. There are a great many cases which come on the border line in everything, but I think there are a vast number of cases in which you would say that the pain is mental pain, and not physical?—I do not think that physiology can really separate the two.

14099. I am not using any scientific language. I am using the language of every day conversation. In a certain sense, of course, you may trace mental pain to certain physical causes?—I quite see what you mean; it is that mental pain is the worse form of pain.

14100. There is a great difference between what we call a broken heart and a broken leg?—Yes.

14101. You seem to think they are the same thing?—No, I do not admit that, if it is taken down in evidence.

14102. (*Sir William Collins.*) Is the mental pain protective, too?—I believe that it is protective, because it is followed by reaction.

14103. (*Mr. Ram.*) Would the pain caused by an operation for purposes of experiment be protective; is the cutting of an animal's skin protective to the animal?—If you take the condition in which you could see the animal's reacting mechanism it would be protective. What I want to show is that the protective mechanism must be there for meeting the contingencies which will probably arise.

14104. (*Chairman.*) What I put to you is this: If you inflict a pain upon an animal, and you want to do an experiment upon it, you do not do it to protect the animal against anything, the pain that you cause is incidental to your making the experiment?—Taking into account all the conditions which you mention, the

reactions are not actually protective, but in ordinary conditions, if an animal were to get such a cut as that, and it were kept alive, the reflex reactions would then be protective.

14105. But the pain that you would inflict would protect no animal?—In that individual case it would not be protective unless the pain was enough to produce syncope.

14106. It would be protective against something that it would not suffer unless you caused it?—But I say that even if I caused it, it might produce syncope, so that the animal would not suffer pain. There is only one other point which I think ought to be recognised. One of the reasons why vivisection is objected to is entirely from the theological point of view, and that comes out in the first chapter in this book, "The Shambles of Science." It is believed that physiologists are rank materialists. I for one absolutely deny it. The chief arguments in favour of vitalism, the modern arguments in favour of neo-vitalism, have come from physiology. The opposition from the clergy to vivisection largely comes from the fact that they believe that all physiologists are materialists. There has always been, so far as I know, a division in physiological thought—there have always been two schools of physiology, the materialistic school and the vitalistic school. The vitalistic school is increasing in force, and it is quite unfair for the writers of "The Shambles of Science" to maintain that physiologists are materialists. My experience as a teacher is that the students often come from the study of physics and chemistry, from their ordinary studies, and from their reading of the ordinary literature of the day, to start physiology with a materialistic bias, and, judging from their papers in our students' society, the study of physiology is the best corrective of these materialistic views. I should say that many of them change their views from the materialistic side to the vitalistic side owing to the study of physiology. I insist again that the best support of the vitalistic position at the present day comes from physiology.

14107. (*Dr. Wilson.*) The vitalistic side is the agnostic side rather?—A vitalist might be an agnostic. It depends upon the sense in which you use the term agnostic, because the vitalist has a definite position. A vitalist of course believes that there are conditions which cannot be explained by the ordinary terms of physics and chemistry, and is not agnostic therefore in that sense.

14108. (*Sir William Collins.*) How long have you held a vivisection licence?—Fifteen years. I was demonstrator first at Oxford in 1892.

14109. What certificates, if any, do you hold?—I have got a good many. I do not remember what they are now. I could look it up.

14110. Do you hold a certificate to permit you to dispense with anæsthetics?—I do not know exactly what certificates I have, because I have not been doing any vivisection experiments this year.

14111. You are, I think, joint lecturer on physiology?—No, I am entire lecturer; there is no joint lecturer.

14112. I took it from the title page of the book you handed in?—My late colleague is dead, and I am now full lecturer.

14113. As lecturer on physiology are you one of the persons authorised to sign certificates?—No, I cannot do so.

14114. Have you anything to do with supporting applications for licences?—No, I have not.

14115. I understood you to say in the course of your evidence that the Vivisection Act was entirely opposed to the advancement of physiology?—Yes.

14116. Is that opinion held by others engaged in physiological research besides yourself?—Yes, I think so. I have already given evidence as to experiments which I could not do in this country which I could do in Germany. The medical members of the Commission will recognise the importance of understanding the effects of bleeding and transfusion.

14117. I think I gathered your point with regard to the experiments in Germany?—It was that we were able to show that after the loss of half the quantity of the red blood corpuscles we could revive an animal and render it perfectly fit.

14118. Without anæsthetics?—Yes.

14119. Did I rightly gather that in your opinion anæsthetics are unnecessary?—Yes, I am convinced that they are often unnecessary, not only in the case of animals, but of men.

Mr. M. S. Pembrey, M.D.

30 Oct. 1907.

14120. For vivisection and for surgical operations?—For vivisection and for surgical operations; and I mentioned the case of midwifery.

14121. Would it be going too far if I were to express your opinion as being that pain is a good thing in itself?—I say that pain is a beneficent and protective mechanism. I have written that in an article which I have recently published, and I am prepared to defend it. It is not a new view at all; it is recognised by surgeons, I believe, that a certain amount of pain is a protective mechanism.

14122. There was a good deal of argument of that kind, was there not, at the time of the introduction of anæsthetics?—Yes, a large amount. When we came to the question of midwifery and the use of anæsthetics, there is not the least doubt that unborn children are injured by the dose of chloroform that is taken in. It may not be a large enough dose to poison the unborn child, but it will interfere with the circulation through the mother's uterus and thereby injure the prospects of the child. The amount of pain that a woman feels in childbirth is protective because the pain will actually inhibit a movement; the pain in parturition will actually produce a condition in the mother which will prevent the too rapid or too slow passage of the child.

14123. I want to be quite clear that I took down your words correctly. I think you said that to abolish pain is absolutely absurd?—To abolish all pain in the condition in which we are at present would be absolutely absurd. The condition would be this: that if we met with an accident we should straight away go from bad to worse without any natural protective mechanism.

14124. Just one word about the marmot. I see that it was implied in one or two of the questions put to Miss Hageby that a post-mortem examination had been made of this marmot. Was that so?—That is Professor Thane's evidence. It depends upon your interpretation of a post-mortem examination. Post mortem means after death.

14125. Did Dr. Thane make any further *post-mortem* examination than that which honourable members have made to-day?—Yes, it was further, for the reason that the animal was much fresher then; it had not long been preserved.

14126. Was there any *sectio cadaveris*?—No, but it is absolutely correct to say that there was a *post-mortem* examination. There was a *post-mortem* examination in the strict sense—that is to say, the body was examined after death and under much more favourable conditions, because it was fresh, but there was no cut made.

14127. You mean that there was a *post-mortem* examination in the same way that we have made a *post-mortem* examination to-day?—Yes, but I do not think that was a thorough *post-mortem* examination to-day. I wanted you to let me cut through the skin and demonstrate to you and make you admit that its spinal cord has not been cut.

14128. I understood you to say that you drew a distinction between a brainless frog and a pithed frog?—Yes.

14129. You say that the law makes it necessary that the cerebral hemispheres should be destroyed?—Yes.

14130. I do not remember it in the Act?—Because the experiment must not be one calculated to cause pain. All the evidence shows that the pain is connected with the cerebrum. I can give examples of that.

14131. I only wanted to know whether there is any definition of pithing laid down in the Act?—So far as I remember I do not know of any.

14132. Would there be a difference in the physiological manifestations visible in the case of a frog which had only been deprived of the cerebral hemispheres compared with one which had only the spinal cord left intact?—Yes.

14133. Should I be right in thinking that in the former case purposive movements would be present as they would not in the latter, to the same amount?—No, not of the same order; of a different order; but they would be present in both cases.

Mr. M. S. Pembrey, M.D.

30 Oct. 1907.

14134. Should I be right in thinking that the higher order of purposive manifestations would be present in the case where the cerebral hemispheres alone have been destroyed?—Yes.

14135. And you compared the condition of a frog to that of a brainless monster?—Yes.

14136. Do you think that purposive movements even of a higher character do not imply possession of consciousness?—I say not so far as one can judge. Shall I give you the reason? We can only judge of consciousness from ourselves philosophically—that is the first point. Then we must go to other people. If you take the case of a man with a section of the spinal cord (I have made the observation several times) that man with a fractured spinal cord will perform purposive movements—he will draw up the leg if tickled; but if he is asked whether he feels the tickling he says, No. He knows nothing about it unless he sees the movements.

14137. Do you not draw a distinction between reflex actions and purposive movements?—These movements are all purposive?—Further, I have seen the case of a woman, who was pregnant at the time, with a fractured spinal cord in the dorsal region. She was brought into the hospital in a condition of paralysis. The physicians and surgeons in charge of the case were doubtful whether abortion should be produced in the interests of the woman. They consulted Dr. Mott and myself from the physiological point of view, and we recalled at once the physiological experiments done by Goltz in Germany, which showed that pregnant animals with a section of the spinal cord could go quite safely to full term. This woman went to full term, and—this is what I want especially to draw attention to on the question of consciousness—all the complicated movements of pregnancy, all the movements in connection with the alteration of respiration, straining movements, and contraction of the uterus went on, and the woman was absolutely unconscious of the fact that she was in process of delivery; although she knew the condition from previous experience, being the mother of several children, she felt no pain at all. That child was born, and until the mother was shown the child and told she had been in labour she did not know that it had taken place. I say then that the common-sense view to take of the matter is this—we cannot be absolutely certain about the question of consciousness except in our own case. In the next case we must take what is told us by other people as regards consciousness. They may or may not tell us the truth. We can only argue from our own consciousness and from what other people who have a fracture of the spinal cord tell us about their condition of consciousness, whether an animal with its spinal cord only has any consciousness. That is a perfectly fair, straightforward statement. That is the only way. I say that I do not deny that there may be consciousness; I believe myself, for example, that philosophically one should believe in the germ of consciousness in the spermatozoon and in the ovum, and there is no reason to suppose that consciousness comes in at any special time during pregnancy. All life, I maintain, must possess the germ of consciousness. I am quite willing to be perfectly straight on that point, but judging by people with a section of the spinal cord—with a fracture of the spinal cord—they do not feel in the paralysed part, and yet they perform the most complicated purposive movements, such as contraction of the bladder, contraction of the uterus, contraction of the rectum, purposive obviously to get rid of the urine from the bladder, to get rid of the full time child from the uterus, and to get rid of fæces from the rectum.

14138. But all involuntary muscular fibre?—No, certainly not. If you tickle the feet, for instance, they are drawn up.

14139. Those that you referred to are involuntary muscular fibre?—I gave you the most complicated because I thought they were the more important. If you tickle one foot it is drawn up. And those that I referred to are not entirely involuntary muscular fibre, because in the case of parturition there is a large amount of accessory pressure brought about by contraction of the abdominal muscles.

14140. I was referring to your quotation of the uterus, the bladder, and the bowel. Those would be involuntary muscular fibre?—Yes.

14141. Can a brainless frog swim?—With the cerebrum alone removed.

14142. Can a man with the spinal cord divided high up?—The only case that I can draw attention to is this, and the case bears on the question of brainless animals. During the construction of the Forth Bridge a workman fell down, and, falling into the Forth, he struck against a great many planks of timber. There was a boat kept there, and the man was picked up and conveyed to the Edinburgh Royal Infirmary. The man was still breathing at the time, and breathed for some time after, and he showed reflex movements. When a *post-mortem* was made after the death of that man it was found that the entire cerebrum was completely destroyed; the skin had simply kept together the fractured skull; the brain was destroyed, but the lower parts, such as the medulla, were intact, and so he had been able to breathe and perform these reflex actions in the same way that a brainless monster will suckle and cry and can do purposive movements and can breathe perfectly well. That man showed no sign of consciousness.

14143. Can a frog with the spinal cord only left swim?—I have not seen one swim.

14144. (*Mr. Ram.*) With regard to pain I want to make your position clear. I understand you to say that pain is very often protective?—Yes, I believe that pain is very often protective.

14145. That means this, does it not—that when a man or an animal suffers a lesion, the pain produced by that lesion is protective?—Yes.

14146. But if there is no lesion, if you take the case of an animal that is perfectly sound and well, do you justify the infliction of unnecessary pain upon that animal?—You want me to assent to the "unnecessary"?

14147. I want you to answer my question?—I consider that it is perfectly right to inflict pain upon animals.

14148. Unnecessarily?—Not unnecessarily—no.

14149. Do you think it is right to inflict pain upon a healthy animal—I mean when there is no question of protecting mechanism—when you can discover all that you want to discover if that animal is under anæsthetics?—What I should say to that is exactly this. I will be perfectly straightforward. I say that you should not inflict pain if you can obtain the knowledge in any other way; but I say that even where there is an operation, the pain there is of a protective nature; it may produce syncope, and therefore less sensation of pain. Further, I say that the introduction of an anæsthetic may produce complications, so that more experiments may be necessary than if the experiment were done on the animal in a condition of hypnotism, which I offered to show to the Commissioners. That I think is one very important point. These animals pass into a condition, so far as one can see, comparable to hypnotism. If you give them anæsthetics you are introducing a complication which you could remove, and therefore without anæsthetics you actually save life and actually diminish the infliction of pain.

14150. (*Dr. Gaskell.*) Do I rightly gather that you would advocate the abolition of the Vivisection Act altogether?—No, I would not do that. I think only people interested and people who are competent should be allowed to make vivisection experiments—that is to say, there should be a certain limitation that these people have the requisite knowledge, and that no ordinary man without the requisite knowledge should be allowed to cut up an animal or to carry on such experimental work. I think that a licence should be given which covers all experiments, those with and those without anæsthetics, painful or otherwise.

14151. Do I rightly understand you to mean that you would diminish the number of people at present holding licences?—No, I would simply leave it for the Home Office to decide by means of special advisers—such, for example, as the Association for the Advancement of Medicine by Research—whether certain applicants for a full licence are competent people for carrying out experiments in physiology or pathology. There would be no limitation of numbers. The limitation would depend only upon the capacity to carry out the work.

14152. You would not consider that some of the points which you have put before us might be solved by introducing the term hypnotism as one of the anæsthetics under the Act?—Yes, I think that ought to be done. Further, I think that hibernation should also be introduced, because it is known, for instance, that

a hibernating mammal passes into a condition of anæsthesia by natural causes, and I think that all natural conditions of anæsthesia should be introduced in the Act. I am told—I am only speaking from memory—that in Denmark it is lawful to vivisect an animal during the winter when it is in a condition of hibernation, but it is not lawful to vivisect it in summer when it is not in a condition of hibernation. Hibernation is a natural condition of anæsthesia, and we ought to be allowed to avail ourselves of that natural condition of anæsthesia.

14153. (*Chairman.*) If you could satisfy the Home Office that an operation on a hibernating animal did not inflict pain, would you require a licence?—It is left to me to decide what operation is calculated to cause pain, but the difficulty that I find is that I may consider that it does not cause pain, and then the Inspector, who, with all respect, does not know anything about hibernating animals, may say that he does not believe that to be the case.

14154. Exactly. If the Home Office were satisfied that it would not inflict pain upon the animal, you would not require a licence?—No; but the Home Office throws the obligation upon me, and it is very difficult to simply convince them.

14155. Very?—But I am willing to show the Commissioners during this winter hibernating animals and to show them that they do not feel pain from the cut of a knife.

14156. (*Mr. Tomkinson.*) Did I rightly understand you to contend that pain of itself is not only protective but a blessing, and that all anæsthetics are a mistake?—No, I do not go so far as that. I say that pain in general, if one takes a wide view of biological processes, is a protective mechanism, and it is in that sense beneficent.

14157. But does not that extend only to this, that if one puts one's hands by mistake into the fire or into boiling water, thereby violating a law of nature, one is punished for it, and pain is naturally beneficent and protective in order to teach us how to obey the laws of nature and not to subject ourselves to danger in future? Surely it goes no further than that?—Yes, I think it goes further than that. How otherwise do you explain the pain that we feel with a fractured leg and the pain goes on and the pain is still protective after the fracture?

14158. I confess that I cannot see the analogy between that and the infliction of gratuitous pain upon an animal?—I gave you an example of the infliction of gratuitous pain upon an animal without anæsthetics which produces a condition of shock, so that there is less circulation of the blood and therefore the animal's brain is not so active and it does not feel pain so much, and therefore to that animal upon which you inflict pain, that pain is actually protective in the example which I have taken.

14159. Now I want to ask you a personal question?—I am quite willing.

14160. If you had to undergo a very severe operation yourself, say the amputation of the thigh or some very severe skin lesion, do I rightly understand that you would think anæsthetics a mistake?—I should consider the question of what would be the effect of the operation and the effect of the anæsthetic. For a small operation I should have no anæsthetic. I have had my lip sewn up without anæsthetics, and the pain is much less than the trouble caused by the anæsthetic. I have seen a man come into the theatre and sit down in the chair and without moving a muscle have a cancer cut out of the lip and have the lip sewn up and march out. If you give an anæsthetic you forget that one of the effects of an anæsthetic is pain. If you go round the wards after anæsthetics have been given, you see patients vomiting from the effect of ether. Is not vomiting painful? I am certain that in many cases in dentistry also, people suffer considerable pain afterwards from the anæsthetic used. In the case of an animal or man if the pain to be inflicted is of a trival kind an anæsthetic is a greater discomfort than the slight infliction of pain. That is my candid view.

14161. Surely you do not contend that the horrors of the cockpit on board a vessel in action and of field hospitals have not been marvellously mitigated by the blessed discovery of chloroform and other anæsthetics?—But these things also bring disadvantages. There is no doubt that the excessive use of anæsthetics is a modern danger. In proof of that is the death roll from anæsthetics. I have seen cases of people dying—of children dying from an anæsthetic given for simple operations like circumcision. I have circumcised children without anæsthetics. If they cry it does not matter; it is much better that a child should cry and moan than that its life should be lost. That circumcision is not such a serious operation is shown by the fact that the ordinary medical man does circumcision under anæsthetics and the Jewish non-medical man does it without anæsthetics. There is an exact case in point in which the introduction of anæsthetics has done a considerable amount of harm. Take also the case that I gave you of midwifery. The pain that a woman suffers in childbirth is protective. Extend the analogy of the use of anæsthesia and every woman in childbirth ought to be given an anæsthetic. What would be the result? You would make the nation more degenerate, if possible, than it is at present. And the very idea that women require anæsthetics during childbirth, I am convinced, has done a good deal towards bringing about the decrease in the birth rate—that is to say, women will rather take preventive measures or produce abortion, will rather be immoral, than suffer a certain amount of pain. It is really owing to the nonsense talked about destroying the bad effects of a small amount of pain. A small amount of pain is part of the scheme of nature, and should be so recognised.

Mr. M. S. Pembrey, M.D.

30 Oct. 1907.

14162. One question more on another point. You mentioned having performed and seen performed the operation of castration. A good deal has been made of that from certain quarters before this Commission. You have seen it performed on sheep?—In hundreds of cases or more.

14163. And on pigs?—Yes.

14164. It is very momentary?—No; it is a short operation if it is done efficiently, but the man is an ordinary farmer in most cases. I will tell you the way it is done if you like.

14165. The effect upon the animal is apparently very slight?—I will not admit that. The lamb is taken by its four legs.

14166. I do not want a description of it?—But I cannot agree to your view that it is momentary pain. It is not. The lamb is taken by the four legs by one man. Then the farmer—this is exactly the way I have seen it done—seizes the scrotum, slits it with a penknife on one side, seizes the testicle, which is a sensitive part, with his teeth, which is quite a good method, pulls on it, and cuts it off with the knife. The operation is then repeated on the other side, the other testicle is removed and the lamb is put down. You see at once the condition of depression. The lamb, which was jumping and frisking about before the operation, stands with its tail between its legs in a marked condition of depression. That depression—I say nothing against it—is protective; it will keep that lamb quiet and that lamb's scrotum will quickly heal up, I grant you. But there is the depression; it is not only for a moment that it feels pain.

14167. But in the case of bulls, certainly, and of horses, it is a necessary operation, we know, for domestic purposes?—Why?

14168. Because they could not be kept?—Why? I can understand that it is advisable, but I do not see why it is absolutely necessary.

14169. Entire horses could not be used for draught purposes in towns and other places; they would not be amenable to discipline.

14170. (*Dr. Wilson.*) I think you said that you had not performed any vivisection—I mean cutting experiments—this year?—Not so far as I remember.*

14171. But you are a lecturer on physiology?—Yes; but I have done the experiments that I have mentioned with carbon monoxide.

14172. What I want to get at is this, that you did not consider it necessary this year, at all events, to give experimental illustrations of your lectures?—Not experiments under the Act—that is so. So far as I know I have done no experiments under the Act.*

14173. You have done no experiments on dogs?—I can state on that point that I do no experiments on dogs at all.

* *The witness subsequently wrote that after reference to his lecture note-book he found that he had performed three experiments.*

Mr. M. S. Pembrey, M.D.
30 Oct. 1907

14174. Yet Guy's Hospital is a large school of medicine?—Yes, I suppose I have about 70 or 80 fresh men every year, and of course those men do physiology for two years, so I may have practical classes of 75 men.

14175. You do not consider it necessary to use a dog for experimental illustrative purposes?—I have not used a dog at Guy's for illustration of experiments at all. I use rabbits, rats, and guinea-pigs. I am very fond of dogs, and if I want to vivisect, and can get a rabbit, rat, or a guinea-pig I do it in preference to vivisecting a dog.

14176. But even those experiments you dispense with. You can teach physiology thoroughly without?—I can teach physiology without experiments on dogs; but there are certain experiments of course which can only be done upon dogs.

14177. But you do not consider them necessary for teaching physiological courses?—In my case I do not use dogs for illustration of lectures.

14178. Then with regard to feeding experiments, do not you think that more knowledge would be gained by experimenting on human beings?—Yes, experiments have been done on fasting men. But the point that I want to bring out is that the reason why one takes hibernating animals is that in their case the deposition of fat is brought up to a point which is found in no other animal.

14179. But men do not hibernate?—No, but the deposition of fat takes place when the animals are not hibernating, so that from the point of view of the condition in men it is really useful to do this. The only other way of experimenting, which has been done, is to use fattened geese.

14180. I threw out that hint, because I was reading the other day that Professor Wiley has instituted or started what his students call a poison squad; that is to say, a certain number of students volunteer for feeding experiments and experiments with drugs?—I think that to safeguard the students those experiments should be preceded by experiments upon animals. Some of the drugs might produce poisonous effects upon the students. I quite agree that those feeding experiments should be done upon man, but in this case the animal may almost double its weight. The process therefore is accentuated, and one can study it better on the marmot, and of course during the deposition of fat the animal is not actually hibernating.

14181. You believe that even severe experiments could be carried out on hibernating animals during hibernation without causing pain?—Yes, when it was in the protective condition of torpor. It has actually been done.

14182. Can you not wake up an animal out of the hibernating sleep?—Yes, if the experiment or the actual performance of the operation took too long, the animal might wake, but the process of waking is a fairly long process, and the experiment should be timed to be over before the animal is fully awake.

14183. But how could you tell?—By previous control experiments. I could give you figures as to the time it takes.

THIRTY-SECOND DAY.

Tuesday, 5th November 1907.

MEMBERS PRESENT:

The Right Hon. the Viscount SELBY (*Chairman*).

Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir J. McFADYEAN, M.B.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. A. J. RAM K.C.
Mr. W. H. GASKELL, M.D., F.R.S.
Mr. G. WILSON, LL.D., M.D.
Captain C. BIGHAM, C.M.G. (*Secretary*).

Colonel DAVID BRUCE, C.B., F.R.S., R.A.M.C., called in; and Examined.

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.
5 Nov. 1907.

14184. (*Chairman.*) You are a Colonel in the Royal Army Medical Corps?—Yes.

14185. And you are a Fellow of the Royal Society?—Yes.

14186. A member of the Advisory Board, Army Medical Service?—Yes.

14187. And you have acted on the Sleeping Sickness Commission of the Royal Society in 1903?—Yes.

14188. And you were Chairman of the Mediterranean Fever Committee of the Royal Society in 1904-6?—Yes.

14189. For a good many years past, I believe, you have been accustomed to perform experiments on animals in the study of disease?—Yes.

14190. Would you tell us, generally, the occasions and places at which you have been so employed?—After I came into the service, I was stationed at Malta for five years, from 1884 to 1889, during which time I worked at several medical subjects, among them, the principal one, from a medical point of view, being Malta fever. Then in 1889 I went to Netley Army Medical School and remained there five years as an assistant professor of pathology.

14191. And did that involve the study of bacteriology?—Yes; I was bacteriologist there.

14192. And animal experiments?—And animal experiments. Then in 1894 I went to South Africa, and soon afterwards went up to Zululand, where I remained for some two years, working at a disease called nagana, or the tsetse fly disease, which was causing a great deal of destruction of cattle up in Zululand, and giving the Government a good deal of anxiety.

14193. It was not at that time ascertained to be identical with the tsetse fly disease, I think?—No. Then in 1897 I returned to Natal and shortly afterwards began working at a very serious disease of animals called South African horse sickness, and after that the war began and I was put on a commission to study dysentery and enteric fever in soldiers, especially in the field, and there, of course, there was a slight amount of animal experimentation, but very little, as we were up in Pretoria, surrounded by the enemy, without any books and without any animals; the only animal we could get to use would have been the horse, and that is too large, of course, for ordinary subjects.

14194. Then you were not engaged in experiments on animals during the time you were in the field?—No, on account of our being in a beleaguered town without any opportunity. But, in my opinion, you could not work at dysentery or enteric fever with any chance of success without animal experimentation. It was only want of animals that prevented our working in that way at that time. Then I came to England in 1902, and in 1903 I went to Uganda to study sleeping sickness. I remained there some seven months, and on coming back to England in 1904 I became chairman of the Mediterranean Fever Com-

mission for the study of Malta fever. At the present time I have a licence to perform experiments on animals at the Royal Army Medical College, but at present I have not much opportunity of doing research work on account of other duties.

14195. You have had very large experience, at any rate, spread over a good many years in animal experiments?—Yes.

14196. And you have had an opportunity of forming an opinion as to the value of them in advancing medical knowledge?—I have.

14197. What is your opinion, generally, on the subject?—My opinion is that it is the most valuable method we have of advancing medical knowledge, and without it we could hardly advance a single step safely. These questions are so complicated, and one is so apt to fall into error, that unless each step is checked by animal experimentation one soon goes wrong.

14198. And have you observed during your twenty years' experience advances made in knowledge by means of experiments on animals?—Yes, certainly.

14199. And in the method of dealing with disease as well as the cause of it. I mean with regard to the serum treatment more especially?—Yes, I think I can say that.

14200. Have your experiments been more directed to the cause of disease?—Yes, my work has been nearly always on the causes of disease with a view to their prevention on broad lines rather than on drug or serum lines.

14201. You are going to tell us, I understand, what your experience is with reference to the causes of disease in some special cases of disease that you have dealt with?—If you please. I have worked at many different things, of course, but I have especially worked at three diseases, namely Malta fever, nagana, and sleeping sickness. I think in Malta fever you have a good example of the result of experimental work in elucidating the natural history of the disease and finding out how the infection is carried from one animal to another. The result of this work has been very striking; that is to say, we have had in the garrison at Malta an average of 700 men down with this fever, for, on an average, 120 days each up to last year. This year to the end of August there has not been a single case in the Navy, and only six cases in the Army, a reduction from 700 down to six; and during the two worst months of this year, July and August, there has not been a single case in the Army or in the Navy in Malta. So that there is yearly saved to the State the services of almost a whole regiment of soldiers, and 700 men from remaining in hospital 120 days with a painful disease, a disease which very often shatters the health for years and sometimes for a lifetime.

14202. Will you describe what the nature of the disease is as regards the pain and the suffering of it, and the length of time it lasts disabling a man?—It is a disease which is characterised by its extremely long duration; that is to say, the men remain, on an average, some 91 days in hospital in Malta, and as most of them are invalided to England and spend another two months or so in hospital here, you can put down the average duration of this disease at the extraordinarily long time of four months, or 120 days. Of course, it lasts much longer in some cases.

14203. You mean before they can be discharged from hospital?—Yes, before they can be discharged from hospital. Many are invalided from the service altogether, and a certain percentage of them die. Some cases of this fever last as long as three years, rendering the man absolutely incapable of work of any kind during this time; and two years is by no means an uncommon duration. In fact, it is a disease of very long duration; it is characterised by extreme weakness; that is to say, a man is brought down to the very edge of the grave without absolutely dying; he is extremely emaciated; he suffers from severe pains in the joints and nerves, and altogether we look upon it as a more severe disease than even enteric fever. Although the mortality in the case of Malta fever is not nearly so large as in enteric, on account, probably, of the different anatomical regions that the two diseases attack, enteric fever attacking the intestine and ulcerating it, very often giving rise to death by perforation of the intestine, whereas in Malta fever there is no ulceration of the intestine, and therefore that is one reason, no doubt, why the mortality is less.

Colonel D. Bruce C.B., F.R.S., R.A.M.C. 5 Nov. 1907.

14204. Is it widespread as well as serious?—Yes.

14205. You speak of it as Malta fever. Is it confined to Malta?—No, it is found all over the world. It was first studied in Malta, hence the name. The Americans found it in the Philippines lately, and it has also been found to be very widely spread in South Africa, in the Orange River Colony, and in Kimberley and other parts of Cape Colony. It is also found in Egypt, and generally round the shores of the Mediterranean, and it has also been found in Arabia, India, China, the Fiji Islands, North and South America, and the West Indies, so that you may say it is a world widespread disease in the sub-tropical and tropical regions of the earth.

14206. And what is the particular micrococcus that you find causes it?—The parasite which causes it has been called the *micrococcus melitensis*. It is a minute bacterium, which, if you magnify it a thousand times, is just visible to the eye, and it is a parasite which can only live in the warm bodies of animals, on account of its requiring a high temperature for multiplication. It multiplies very little, or not at all, at ordinary temperatures, but when kept at the temperature of the blood it multiplies fairly rapidly, so that you may call it a parasite that depends upon its parasitic existence for its own existence. It cannot live outside the body and multiply there. It can only live in a dry condition, retaining sufficient vitality to set up again its activity if it again reaches the blood of a warm-blooded animal.

14207. It is called Malta fever because it was first found there or studied there?—It was called Maltese fever because it was first studied there. It was studied by Army medical doctors who go there on service, and at that time it was thought to be fairly well restricted to Malta, so that naturally, being one of these local diseases, or at least, thought to be local at that time, it received a local name. It has other names, for example, rock fever in Gibraltar.

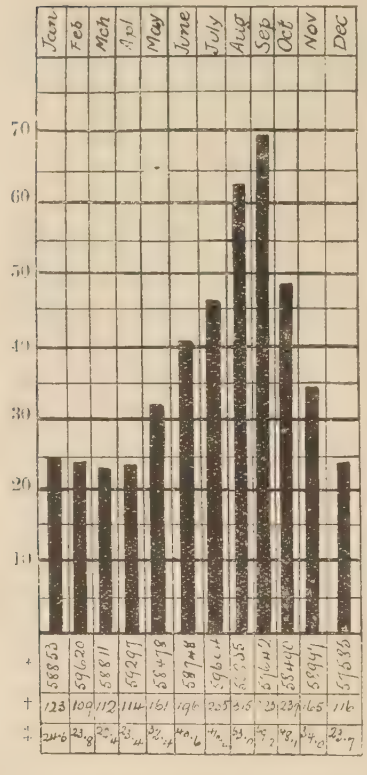
14208. (*Sir Mackenzie Chalmers.*) Is that the same fever?—Absolutely the same fever.

14209. (*Chairman.*) And in these other places it is not always known as Malta fever?—No; in Kimberley it is known as camp fever, and every place gives it its own name. Now, of course, it has been pretty well worked out, and everyone knows of it, and at present it is usually called Mediterranean fever. In the nomenclature of diseases it is known as Mediterranean fever, with the synonym of Malta fever. The change from Malta fever to Mediterranean fever was a little politeness to the Maltese people; but I think it is better to keep to the term Malta fever until they do something to clear their island of it. That is to say, we have suffered a great deal in the past from Malta fever, and therefore I always encourage the use of the term "Malta fever" in order to drive the Maltese to try to remove the stigma from their island. After they have purified their herds, then we will see about renaming this fever. The Italians call it the septicemia of Bruce; so we might call it by this name, as I have no objection to have my name associated with a disease, after they have purified their herds.

14210. You have a table, I believe, that you can hand in showing the amount of Malta fever in the troops at Malta at different times in the year?—Yes.

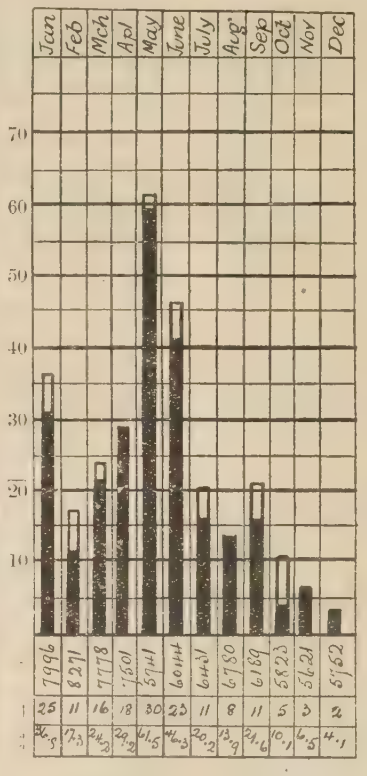
MONTHLY PREVALENCE—RATIO PER 1,000 OF STRENGTH EXPRESSED IN TERMS OF AN ANNUAL RATIO.*

CHART I
1899 TO 1905.



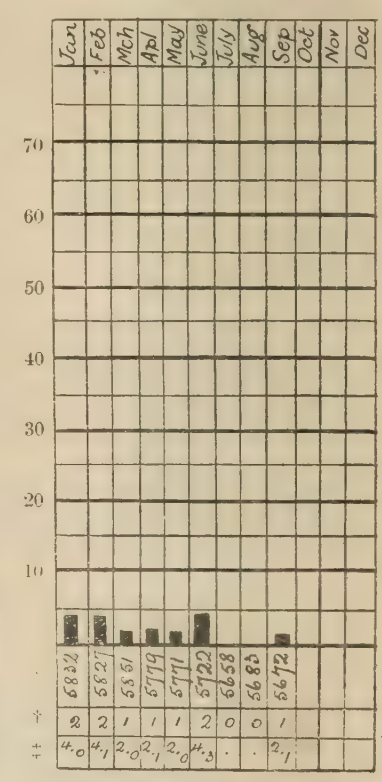
* Aggregate strength for 7 years.
† Admissions.
‡ Ratio per 1,000 of strength.

CHART II.
1906.



Readmissions shown thus.
* Average strength.
† Admissions.
‡ Ratio per 1,000.

CHART III.
1907.



* Average strength.
† Admissions.
‡ Ratio per 1,000.

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.

5 Nov. 1907.

14211. That is from 1899 to 1905?—Yes, that is the chart made up from those years.

14212. It is very high in August and September?—Yes.

14213. And less just in the months each side of them and less still in the more distant months?—Yes, but at the same time there is not much to be said in regard to seasonal prevalence. When you make a chart of this sort out of a number of years you get a fixed chart, and naturally in the hottest months of the year, when people are lowered in health and when they probably take more of the infective agent in, there would be more cases; but sometimes epidemics arise in February or March, or December in some years, changing the aspect of this chart and showing that seasonal prevalence has very little to do with the disease. This chart shows that on an average there are some 400 cases of this fever among the soldiers in Malta; and at another part of this paper I give the number of cases for the Navy, and it comes to very much the same.

14214. I think you made it 37.6 per cent. per 1,000 men in garrison?—Yes.

14215. There are about 8,000 men in garrison?—Yes.

14216. Then there are three other tables which perhaps you will put in also?—Yes; the first table is the incidence of continued fevers (including Malta fever, simple continued fever, and enteric fever), among the troops in Malta from 1897 to 1906. That is put in to show that a number of cases that are returned under the name of simple continued fever are probably cases of Malta fever, and when Malta fever disappears a number of these simple continued fevers also disappear. Then in regard to Table 2 the incidence of Malta fever among officers, women and children in Malta, you find that the incidence among the officers is about four times as great as among the men. We discovered the reason for this when the cause of the mode of infection of Malta fever was discovered to be due to the milk of goats. Naturally, the officers drank more milk than the men.

14217. You mean that they were in the habit of drinking more milk than the men?—Yes.

14218. Therefore, when you discovered that, that explained the greater incidence among officers?—Yes, we could not understand before that, seeing that the officers live in good quarters and have good food and are not exposed to the same risks—that is to say, they do not go among the lower classes as much as the private does—why they, their wives and families, were much more struck by this fever than the private soldiers; but the moment we found out that this fever was due to the milk of goats, then the habits of the officers and their families in the way of drinking much more raw milk than the soldiers explained it at once.

14219. In Malta, I understand, the milk used is the milk of goats generally, just as it is the milk of cows here?—Yes, there are very few cows in Malta; even if you ask for cows' milk, and the contractor says it is cows' milk, in all probability it is goats' milk. The goat is the animal that supplies milk in Malta.

14220. Then the other table is to the same effect, showing the number of officers, non-commissioned officers and men invalided from Malta?—Yes. In the Army we were not in the habit of invaliding the men as much as in the Navy. In the Navy it was made a rule that if a man had Malta fever the moment he was able to be invalided to England he went. Of late years, for example, in 1905, there were 21 officers and 382 non-commissioned officers and men invalided from Malta, so that the habit of this invaliding was getting more marked in the Army than it had been. It was found that the men remained debilitated for such a long time that it was better to invalid them home to England. That, of course, means a great deal of expense to the State, providing passages to England, and treating the men in hospital in this country for some two months or more.

* *These charts were afterwards substituted by the witness in place of the one referred to during the evidence, in which the figures did not go beyond* 1905.

The following are the Tables handed in by the Witness.

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.

5 Nov. 1907.

TABLE I.

INCIDENCE of continued Fevers, including Malta Fever, simple continued Fever and Enteric Fever, among the Troops in Malta, from 1897 to 1907.

Year.	Total admissions for continued Fevers.*	Total Admissions for			Malta Fever Ratios per 1,000.		Simple continued Fever. Ratios per 1,000 admissions. A
		Malta Fever.	Simple continued Fever.	Enteric Fever.	Admissions.	Deaths.

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.

5 Nov. 1907.

TABLE III.

NUMBER of Officers, Non-Commissioned Officers and Men invalided from Malta to England for Malta Fever, 1897 to 1907.

Year.	Officers.	Non-Commissioned Officers and Men.
1897	9	110
1898	10	121
1899	8	120
1900	15	43
1901	9	92
1902	21	36
1903	21	133
1904	14	100
1905	21	382
1906	12	165
To end of Sept. 1907	—	1

14221. So much for the severity and distribution of the disease. The most important part, which follows, of course, is the question of animal experiment in the investigation of Malta fever. Will you now come to that?—In regard to the discovery of the germ causing a disease, it is very easy to be led astray, because when people are sick their tissues are very often invaded by other micro-organisms, so that when you examine a man's blood or examine the various excreta you may come across a bacterium, or bacteria, and it is difficult to know that you are dealing with the right one. And it is very important, of course, to know that you are really dealing with the cause of the disease, because, naturally, it would be a waste of time to work up the natural history of another harmless bacterium which had got in by accident; so that after one has found a germ in the body of a man or animal suffering from a disease, it is very useful if you can find one of the lower animals that will take the disease and so prove that the germ you are dealing with is the real cause.

14222. But it is when you have found one of these particular bacilli, wherever you find it, that it is important to test in a lower animal what its effect is?—Yes. It was laid down years ago by Professor Koch, the famous German bacteriologist, that the proof that a micro-organism is the cause of a certain disease must fulfil three conditions—(1) you must find the same micro-organism in every case of the disease, (2) you must be able to cultivate that micro-organism outside the body in such a way as to remove it from all products of the body, and (3) you must be able, by the injection of this artificial growth into healthy animals, to give rise to the same disease. Certainly, one of the most important things in beginning the study of a bacterial disease is to be able to put your finger on one germ and say that absolutely is the cause of the disease. Having settled that you can go on to study its natural history further. In the case of Malta fever another animal besides man is susceptible to the disease under ordinary natural conditions, and that animal is the monkey. So that after having tried the ordinary laboratory animals, such as the rat, guinea-pig, rabbit, and finding no result from them, I tried monkeys. When one injects this micro-organism into the former animals there is no rise of temperature and no appearance of disease, but in trying it on monkeys one found that they took a fever very similar to the fever in man, that they suffered from arthritic pains, and that, so far as you could see, they suffered in the same way as man did; and, lastly, when they died the same micro-organism was found in large numbers in pure culture in their organs. In this way Koch's three postulates were satisfied, and it was proved that the *micrococcus melitensis* is the cause of Malta fever. And it it difficult to know how you could prove this without animal experimentation, because in diseases such as dysentery you often find in the spleen, or the gall bladder, or the liver various forms of bacteria which have nothing whatever to do with dysentery, but have got in there on account of lowered vitality of tissues, and you might be led to think that they were the causes, or one of them was the cause of the disease, and in that way be led into error.

14223. Did you, by this process, discover what you now call the *micrococcus melitensis*?—Yes.

14224. You ascertained that that was the cause?—Yes.

14225. So far as you could ascertain it by those means which you think are satisfactory?—Yes.

14226. When was that?—That was in 1886.

14227. That was, I presume, by a series of experiments?—Yes.

14228. On monkeys?—Yes. The monkey is an expensive animal, and at that time there was no help given to private pathological work in the Army, so that one had to buy these monkeys out of one's own slender pay, and naturally I did not buy many, but I bought a sufficient number to enable me to say that this micro-organism was the cause of the disease.

14229. (*Mr. Ram.*) As long ago as 1886, did you say?—Yes.

14230. (*Chairman.*) The same bacteria I think you say you got from spleen of men who died of the fever in some cases?—Yes, I found this particular micro-organism in every case of death from Malta fever in man; after death, at the *post-mortem*, one removed a small quantity of the spleen and planted it out in various materials suitable for the growth of these things, and on a particular material and at a particular temperature this particular micrococcus grew, and it was from the growths, of course, on the artificial media that the animals were inoculated; that is to say, you find the micro-organism in the animal, you grow it outside their body, away from the animal, and, thirdly, you inject it into a susceptible animal and give rise to the same disease.

14231. Did you infect other animals from the blood of the monkeys that had the fever?—At that time we could only infect monkeys, because the monkey is the only animal sufficiently susceptible to take the disease by ordinary means; by feeding or by injection under the skin.

14232. Did you use experiments for the purpose of ascertaining how you could convey infection into man, or how it was likely to be conveyed?—Yes. Of course, later on, when we had the Commission, all these experiments were done in large numbers; I do not know how many monkeys were used as experimental animals, but there must have been some 150 or 200 monkeys; we had a large number of monkeys, and in using them they were used in many ways.

14233. That was in 1904-6?—Yes. For example, in finding out how the *micrococcus melitensis* leaves the body (which is naturally a very important thing to find out), it is a minute germ, and it might possibly come out in the expired air, in the urine, or it might come out as the bacillus of enteric fever principally does, from the alimentary canal in the dejecta. Then, of course, in examining how the micrococcus leaves the body, naturally you would examine the sweat, the saliva, the tears, and the other secretions. At the time this work began everybody supposed that Malta fever was due to effluvia, that it was due to this minute micro-organism finding its way into the air of wards from the sick or into the air of rooms from drains, sewers, etc., and so causing infection. Now, to put that to proof, you have to drive thousands of cubic feet through an apparatus in order to collect the micro-organisms contained in the air, and as you collect a number of ordinary air bacteria, you could not, by simple examination under the microscope, distinguish between the *micrococcus melitensis* and these others. So that here it is necessary to use an animal. The animal, as it were, picks out the pathogenic organism, which alone has the power of growing in the tissues and so causing the disease. All the other common organisms found in the air are killed off by the tissues and fluids of the animal, leaving the particular pathogenic one alive, and so its presence in the air can be proved.

14234. How would you infect the animals. By allowing them to breathe this air?—The micro-organisms would be taken from the air into a quantity

of water, that water would be centrifuged in order to throw the solid matter down, and that solid matter in a small quantity with water would be injected under the skin of a live animal. In this particular case, as the monkey was the only susceptible animal the Commission used monkeys. At one time it was thought, for example, that the grand harbour of Malta was the breeding place of this fever. On account of its being used as a sewer for hundreds of years it was until recently in a disgraceful condition, and it was considered that the sailors got the fever when going back to their ships at night. Now, in order to prove that, large quantities of the harbour water had to be examined. For that purpose a large quantity of water is passed through a Chamberlain filter in order to retain the little particles contained in the water, and then removing these germs from the filter you can experiment as to whether they contain the *micrococcus melitensis* by injecting them under the skin of a monkey. If there are any *micrococcus melitensis* they will probably set up the disease, and the one particular germ will be recovered from the animal afterwards, all the other harmless ones having been killed off by the tissues of the animal.

14235. And you found, I understand, from these experiments that the micrococcus was not conveyed either by the air, by the effluvia, or from the harbour water?—Nor from dust collected in suspicious places where one might expect to find it, contaminated places, nor from the air and dust, for instance, of fever wards, or of rooms where cases of the fever had occurred, and so on.

14236. (*Sir Mackenzie Chalmers.*) All those experiments were negative?—Yes.

14237. (*Chairman.*) And by that exhaustive process you came down to what is the only source?—By that the Commission came down to the fact that it was nothing but the milk of goats which conveyed the infection of Malta fever.

14238. (*Sir Mackenzie Chalmers.*) What put you on to the milk of goats?

14239. (*Chairman.*) First, I suppose, you found that it was something that was swallowed?—Yes, it was discovered by animal experiment that infection could be conveyed by the mouth.

14240. Something in food I meant?—Yes, this discovery came as it were as an accident at the end. In an investigation of this kind you naturally examine all the animals round about, in order to find out if any of them harbour the disease. The goat was looked upon by us as the most refractory and the most insusceptible animal we could imagine; we do not consider that the goat is readily susceptible to human diseases; it does not even take tuberculosis, which is such a common animal disease, so that we look upon the goat as the animal that is about furthest away from taking a human disease; and as only the monkey took this disease, and not the rabbit, guinea pig, rat, or dog, we considered that it was very improbable that a goat would take it. But, as a matter of routine, some goats were taken and inoculated under the skin with the *micrococcus melitensis*, and some were also fed on a small quantity of the culture—that is to say, a little of this *micrococcus melitensis* is taken out of a tube and put on the food, so that the animal eats it. These animals were examined afterwards as to their temperature and general appearance, but nothing happened. Now there is a a more delicate way of knowing whether an animal is affected by an infectious disease, and that is by an examination of the blood of the animal with the micro-organism that causes it. The blood of an animal which has been attacked by a particular micro-organism has the power of drawing all these micro-organisms into clumps. It is a very peculiar thing, but it is true that if you take the blood of an infected goat and mix it with an emulsion of the *micrococcus melitensis* in a few seconds all these micrococci are drawn together into little clumps or lumps. You then say this micro-organism has had a certain influence on this animal. So when on examination of the blood of these goats this clumping was noticed, it was seen that something had occurred; but for almost a whole year nothing more happened, and it was only, I think, in the middle of 1905, or the beginning of 1906, I forget which, that, the other methods proving useless or futile, again the goat was taken into consideration.

14241. Do I correctly understand that the goats which you inoculated got Malta fever, or only that it affected the blood in a certain way?—They did not get the fever in the way that we consider characteristic of fevers. They got the fever, but did not show any external manifestations of that fever.

Colonel D. Bruce, C.B., F.R.S. R.A.M.C.

5 Nov. 1907.

14242. They carried about the poison that gave the fever, but did not suffer from it?—Yes, the micro-organism did multiply in their bodies, but it did not give rise to any ill-health, it did not give rise to any fever. By looking at the goat you could not say that that goat was ill—it gave as much milk as a perfectly healthy goat, it was as fat and smooth-looking as a healthy goat, so that it was only by this blood examination that it was suspected that something was occurring.

14243. That is to say, you suspected that the goats had it in them before you put the inoculation in already?—We suspected that the stuff we put in had not died off as ordinary non-pathogenic organisms would when brought into contact with a non-susceptible animal, but that it had gained some ground and was multiplying to some extent, and giving rise to these changes. So that in June 1905 a careful examination was made into this question again, more goats were bought, and before injecting them, or before feeding them, their blood was examined as a matter of routine to see that the blood was all right, and, curiously enough, goats bought at this time gave this same Malta fever reaction; and then the idea struck us that the goats, the ordinary goats of Malta, might be suffering from this fever. So that at once, after having found that they give a reaction, you can examine the blood itself by removing a certain amount of blood from the veins for this micrococcus, and you can also examine the milk, and on examining the blood of these ordinary Maltese goats the *micrococcus melitensis* was found in it, and on going further and examining the milk of these apparently healthy goats a certain percentage of of them were found to contain that *micrococcus melitensis* living in their milk, and that, of course, threw a great flood of light at once on the whole question.

14244. (*Dr. Gaskell.*) Had you previously found out from experimentation that the micrococcus left the body in the milk and the urine?—Yes, in the urine, but not in the milk of human beings. You very seldom find a woman suffering from Malta fever, and at the same time secreting milk; and the monkey, of course, is not as a rule secreting milk in captivity. So that before this discovery was made the *micrococcus melitensis* had not been found in the milk of any animal. After the discovery was made, it was found in the milk of human beings—nursing mothers. But you can easily understand that beforehand one would not think of this.

14245. (*Chairman.*) The important discovery was that it was in the milk?—That was the important discovery, because it at once explained various things in the epidemiology of the disease: that seasonal prevalence had little or nothing to do with it; that whether it was a large town or small village nothing in different methods of sanitation seemed to matter; the curious fact that officers were much more struck by this fever than the privates was also explained; and after more work the Commission came to the conclusion that the only way that a man takes Malta fever in Malta is by the drinking of goats' milk. Perhaps once in a thousand times he may take it in some other way, but you can sweep all that aside; the drinking of goats' milk is the main path of infection, and naturally, of course, it is easy to stop to a great extent our sailors and soldiers drinking goats' milk, so that when the thing was once brought to the attention of the authorities, at once the disease was blotted out of the garrison of Malta, and from what I have said, of course, we look upon that as a very important and useful feat to have accomplished.

14246. Will you tell us what measures were taken then? Your Commission I suppose reported that you had discovered this particular micrococcus to be the cause of the disease?—Yes.

14247. Then were orders given that no goats' milk should be supplied to the troops?—At first there was a certain amount of hesitation, and an attempt was made to sterilise the milk by boiling and that kind of thing; but we soon pointed out that while boiling milk, if it was properly done, of course, would sterlise the milk, yet when you are dealing with the natives of these countries you never can trust that the thing is done properly. There is a small test by which you can tell whether milk has been boiled or not, and by carrying that in your pocket, and by going into the hospitals and demonstrating to the head of the hospital that his milk

Colonel D. Bruce, C.B., F.R.S., R.A.M.C. — 5 Nov. 1907.

was not boiled when he thought it was, after a month or two of this the conclusion was come to that no goats' milk whatever was to enter any military or naval hospital, or any ship or regiment. The General gave an order that not a drop of goats' milk was to be used, and all the troops were put on condensed milk, and it was then that the great fall in the number of cases took place.

14248. Down to six cases instead of 700?—Yes, six fresh cases.

14249. Have you any doubt that your discovery was correct, and that you found the real cause?—I do not think there is the slightest doubt—it is so marked.

14250. You have spoken about Malta, and you have told us that the same fever exists in other places. Has it been traced to goats in those other places?—In other places they have a very strong suspicion of the goats, and certain goats have been found to be affected; but, of course, the thing has not been investigated as closely as it has been in Malta.

14251. Take, for example, a quite distant place, the Philippine Islands, where you say it exists; have any experiments been made there as to what causes it there?—I do not think so. I do not know that I know the whole literature of the subject in the Philippine Islands; but all I think that they have done at present is to find that men do have it there.

14252. Does this fever exist in places where goats' milk is not used?—Not that I know of. In India in the Punjaub, where it is found pretty frequently, goats' milk is used; and down in the south of Africa they have been bringing evidence forward lately that the more goats are used the greater the prevalence of this fever.

14253. Is it found in places where goats' milk is not used?—I do not think so. I would not say at the present moment that in every country in every part of the world the goat, and the goat alone, is responsible, because it is evidently a disease which affects in a mild way many species of animals; that is to say, that even a cow, if it was exposed to infection, would become infected. So that if you removed all the goats from Malta to-morrow and replaced them by cows, you might find yourself in the same position after some years.

14254. Do the natives go on drinking goats' milk?—Yes.

14255. Do they suffer from fever?—Yes; but, of course, not to the same extent apparently that the soldier suffers. The soldier goes there a susceptible man. The Maltese are always living among it. I imagine that nearly every Maltese has this fever at one time or another; but they drink it with their mother's milk, and they have it when they are young, so that they become, as it were, immune to it. The incidence amongst the Maltese at the present time is put down at about a tenth of the incidence the garrison suffers. But, of course, the diagnosis of the fever away in these country villages by country doctors, and the desire of those people not to offend their patients, and all that kind of thing, makes the notification returns very unreliable.

14256. (*Sir Mackenzie Chalmers.*) Is one attack of this disease protective?—That is not absolutely proved, but in my opinion it is to a great extent protective We very seldom find a soldier coming in suffering from a second attack, and the monkeys experimented with, after having recovered from a first attack, showed no signs of taking a second when infected again.

14257. They were resistant?—Yes.

14258. (*Sir William Collins.*) At what interval?—That, of course, is only an interval of about a year or so. This matter was not pushed very far. I do not think it is at all proved that one attack of enteric fever or Malta fever will make a person immune not nearly as much as scarlet fever, smallpox, or measles; those fevers do not seem to confer such marked immunity, and it is really a difficult question and a question that I would like to have answered—it has a bearing on our system of anti-typhoid inoculation in the Army as to whether one attack of typhoid fever protects sufficiently.

14259. (*Sir Mackenzie Chalmers.*) Or for a specified period?—Or for a specified period.

14260. (*Chairman.*) Supposing that you had been sent to Malta to discover the cause of Malta fever with a positive prohibition against any experiments upon animals, how would you have set to work?—Of course you could have discovered the micrococcus in the dead bodies of men, but then you would have stopped there, I think, because if you wanted, for example, to find out whether goats suffered you could not inoculate a goat; you could not even take a drop of blood from a goat's ear. I think you would have been stopped in the investigation at the outset.

14261. Supposing that you had suspected the goat, which you say you would not have done except after these exhaustive experiments in other directions—supposing you had happened to light upon the idea that it might have been due to goats—what would you have done?—In the first year of the Commission a Local Government Board man, who was recommended by Mr. Power, went out to Malta to work at the fever from the epidemiological standpoint, to examine by the method of statistics the incidence among those who drank water, beer, milk, and all that kind of thing, in order to see whether any light could be thrown upon this fever; but after very hard work for six or seven months, during which time he lost four stone in weight, he came to the conclusion that milk at least was not the cause; so that the epidemiological way of working at the causation of this fever absolutely failed. We sent out others; we sent out one or two men, and we sent out Colonel Davis, who is a man who worked at it in the same way, and he came to the conclusion that milk was not the cause, showing the difficulty of any other method of discovering the cause.

14262. Supposing you had discovered, as you might, from accidental observation in a place, that the people who drank goats' milk got it and that people who did not drink goats' milk did not get it, and that made you suspect the goat as being the cause, and that you had found this bacillus in the milk of the goat, would that have been sufficient?—I quite agree that it would not have been anything like so complete as it was after the experiment, but would you upon that have come to the conclusion that that bacillus caused the disease?—I think so.

14263. If you had found it in the spleen of all men who died of it, and you found it in the goats' milk, and that men who drank goats' milk died of this disease or got it, and that others who did not drink goats' milk did not get it?—Certainly that would be a very strong argument, and one would certainly be able to take practical measures to prevent the disease.

14264. By isolating people from goats' milk and testing it in that way you might find that you were right—you might be corroborated by the result in your conclusion that people who did not drink goats' milk invariably avoided the fever and that those that took it did not?—Yes; but what I would say with regard to that is that you would depend upon something fortuitous, some sort of accident, to make your discovery; whereas when you begin the study of a disease by the experimental method you simply go along, as it were, a well-marked track. You begin at one end and you simply go slowly forward, carefully scenting it out, and you feel sure you must find out the cause of the disease if you only have enough patience and perseverence.

14265. You go along a path which must lead you to the result. In the other case you are walking along a path with a vast number of turnings, and you do not know which is the right one?—In the one case you might sit for 20 years waiting for some fortuitous circumstance to arise which would point out the particular thing which you want to arrive at; but in the other case you begin working just as a man begins working at mending a road or any other piece of work, and you know that within a year, or two or three years, you stand a very good chance of finding out the cause of the disease and its mode of infection, or you find out the reason why you cannot find it out. For example, in cancer you cannot see anything, and you cannot get any further forward even after years of work, because there is nothing to see or cultivate or work with.

14266. (*Sir John McFadyean.*) But that experimental routine method is only certain to be successful in cases of human disease when that disease is communicable to an animal?—Yes.

14267. (*Mr. Ram.*) As I understand, the use that you made of animals, where they were of use to you, was that you wanted to eliminate all other cocci except the particular one that you wanted to find?—That is only one small part.

14268. You said that you tested these animals, and

that other micrococci might be taken up which become dead in the tissue of the animal?—Yes.

14269. But that only this latest one ultimately survived, and you found it in other animals?—Yes. That is the very beginning to prove that the particular micrococcus is the cause of the disease.

14270. But this particular micrococcus, given to animals, did not help you further than that?—Yes, it did.

14271. How?—How did the goat help us when we took a drop of blood from its ear? The goat was helping us very much, when we found the micrococcus in her blood; and the goat helped us very much when we fed it on the micrococcus, and found that, by again taking a drop of blood from its ear, a certain change had taken place, which showed that this micrococcus was living and multiplying in the interior of that goat.

14272. But with regard to other animals, monkeys and so forth, what you wanted was to enable you to recognise this particular micrococcus?—But we did not know that the micrococcus in milk, for example, was in a condition to give rise to the fever. By taking 30 monkeys and giving each one a drink of milk and finding that 25 or 26 got the fever, we had a very strong argument that the micrococcus was in a virulent form in the milk, and that the same thing would probably occur in man.

14273. After you suspected the milk you tried the milk in animals?—Yes.

14274. (*Dr. Wilson.*) Was the milk fresh when it was given to the monkeys?—Yes, quite fresh.

14275. (*Sir Mackenzie Chalmers.*) You found that the milk was not merely a concomitant, but was the cause?—Yes, we found that it was the drinking of the milk that gave rise to the fever.

14276. (*Sir William Collins.*) You mentioned the case of cancer as a case in point. Am I right in thinking that in that case investigation was not restricted to a fortuitous cause?—Yes.

14277. And that investigation has hitherto been unsuccessful?—Yes.

14278. (*Sir John McFadyean.*) I venture to suggest that there would be no objection on any ground to taking blood from a goat for examination if once a suspicion arose that the goat was actually diseased. That would not constitute an experiment even in this country. I submit that such a thing is not covered by the Act, the goat being suspected, and that it is not an experiment, but an operation conducted with a view to diagnosis; that it is analogous to the injection of mallein and tuberculin, which is often done, not with the intention of curing the animal, but with the express intention of killing it?—As I read the Act I cannot take a drop of blood from a rabbit's ear to examine, but I can knock a rabbit on the head and take all the blood in its body to examine.

14279. That is in the case of healthy unsuspected animals?—But these goats looked healthy animals.

14280. (*Dr. Wilson.*) But you suspected them of the disease?—No, we did not.

14281. (*Sir John McFadyean.*) I quite recognise that you examined their blood, although you had not suspected it?—As a routine examination, just as you take a temperature, and we were very much surprised to find that the blood reacted. I was exceedingly surprised, I remember.

14282. (*Chairman.*) You were speaking about accidental discoveries. There was an accidental experiment, was there not, on board a steamship with a cargo of goats from Malta?—Yes.

14283. Will you tell us what that was?—That took place about the time when we discovered the complicity of the goat. After the matter had been reported, of course, the attention of medical men all over the world was directed to it, and I got a letter from Alexandria saying that a sailor had been taken into the hospital there suffering from Malta fever, and mentioning that in all probability it would be found to be due to drinking goats' milk. That letter led to a complete working up of this ship epidemic. It turned out that the Americans had sent over a man to Malta, the Maltese breed of goats being a very famous breed on account of supplying a large quantity of milk, to purchase milch goats and bring them to Washington, there to set up a dairy for the supply of goats' milk for children; it was on account of the tuberculosis question." That man bought 65 goats, put them on board a steamship called the "St. Nicholas," and took them first of all to Antwerp. During the voyage in the Mediterranean the captain and nearly all of the crew—with the exception, I think, of three or four—drank the milk of these goats, and broadly every man who drank the milk took Malta fever; and even when the goats got to America, in spite of all the experience that they had had, the wife of the man who was in charge of them there also took Malta fever, and the man Thompson who had brought the goats from Malta to America died about that time, and there was a suspicion of Malta fever in his case; so that you could hardly have had a better experiment on the action of milk than in that particular case.

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.

5 Nov. 1907.

14284. You do not know, I suppose, what was the history of these goats after they landed?—Yes. We, of course, informed the American Embassy here, and they took care to have those goats thoroughly examined after they landed, after they got to their destination; and I forget the percentage of the animals found to be affected by Malta fever, but it was quite a large percentage. Those animals were then slaughtered, and the healthy ones kept under observation. What has happened since I do not know. I have not heard anything since, but I imagine that even if a case of that sort had occurred under ordinary circumstances it would not have attracted any attention.

14285. That was in 1905 whilst you were pursuing your experiments?—That was the result of our discovery as regards the milk; that is to say the discovery of that epidemic on board that ship was due to our discovery of the fact that the *micrococcus melitensis* was found in the milk; because it was only that which made the man in Egypt write to me.

14286. It was only a confirmation of your discovery?—It was only a confirmation of it, and it would not have been discovered if it had not been for our previous discovery. One of these men was treated at Alexandria for Malta fever, which is a common thing there. Another man, the captain, called at Valetta, and asked the local doctor about his fever, and another was treated at the Seamen's Hospital here, and so on; this ship epidemic would probably never have been noticed if it had not been for the work of the Commission.

14287. (*Dr. Wilson.*) But no precautions were taken with regard to shipping those goats?—No, that was done without our knowledge at all.

14288. (*Chairman.*) Have the same precautions been taken with regard to the disease at Gibraltar as were taken at Malta?—I give in my *précis* of evidence a chart by Major Horrocks, which shows that the Maltese goat has almost entirely disappeared from Gibraltar in the last few years. Major Horrocks is the sanitary officer at Gibraltar. He has examined every goat on the Rock, and he has the power of slaughtering those that he finds affected, so that the precautions taken in Gibraltar are very much greater than the precautions taken in Malta.

14289. (*Sir Mackenzie Chalmers.*) And with what result?—There has been no Malta fever there for some years.

14290. Rock fever has died out?—Yes.

14291. (*Chairman.*) However, we may take it now as an accepted fact, may we, that Malta fever does come from the milk of goats?—So far as human proof can go I think it is absolutely proved.

14292. And you have told us the history and how far experimentation on living animals had a part in the discovery?—I think in any other case the discovery would have been accidental or fortuitous, but by having animals to experiment on, if you can find an animal that is susceptible to a particular organism, and if you can find the organism and grow it outside the body, it is only a question of time to discover the natural history of the organism, and find out some method of stopping the disease.

14293. Then I think you have also investigated nagana or the tsetse fly disease, which are both discovered to be the same now?—Yes, they are both the same.

14294. But that was not known at the time?—No.

14295. That, I think, was in 1894?—I went up to Zululand in the end of 1894. The tsetse fly disease before that was looked upon as being a disease caused

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.,

5 Nov. 1907.

by the poisonous bite of a particular fly, just as a snake bite would poison.

14296. Or as a wasp is said sometimes to kill people in England who are very sensitive?—Yes.

14297. Did you use experimentation on living animals in that investigation?—I used a large number of ordinary native dogs for the purpose, and also horses and mules and donkeys.

14298. Was that for the purpose of discovering a bacillus?—When I went up to Zululand at first, the natives sent me in a certain number of cattle suffering from this nagana. They looked very ill, but one did not know anything about their illness. The only thing to do was to examine them systematically. One of the easiest tissues of the body to get at for examination, of course, is the blood, so that one makes a very careful examination in all sorts of ways of the blood of the animal; and while I was doing that I came across a peculiarly shaped thing in the blood; it was very scarce in the blood of these cattle, but looked as if it was something foreign to the blood. At that time, of course, one was working quite in the dark. In nagana in cattle this particular micro-organism is very scanty; you may examine the blood for several days very carefully without finding one; but in some other species of animals they grow in much greater numbers in the blood, so that when I took as a matter of routine some of the blood of the cattle and put that blood into a dog it was found that the dog rapidly became ill, that its blood was swarming with this peculiar-looking thing, and therefore there was probably some connection proved between this peculiar looking thing and the disease.

14299. The dog is liable to the disease?—Yes, it is an acute disease with dogs; they die in ten days or a fortnight; whereas cattle will live on for a year, and even recover in some few cases. Often they will live for six months or a year or two years with very few of these things in their blood. The discovery that nagana and the tsetse fly disease were the same was a matter of accident. Within a few miles of the hill on which I was living was a fly-belt, and as I had read about this fly disease in books of travel, I was curious to know what the fly disease was. Accordingly, as a matter of curiosity, I sent down one or two horses, some cattle, and several dogs to live in this fly country for a fortnight, and when they were brought back to the top of the hill I examined them and, much to my surprise, I found this same creature living in their blood; and then I began to suspect that nagana and tsetse fly disease were probably the same, and that the disease was really caused by this trypanosome, this parasite.

14300. (*Sir Mackenzie Chalmers*). When the animals came back had they developed any signs of illness?—Yes, dogs develop nagana in a very few days; they had been a fortnight in the country.

14301. (*Chairman.*) You mean that you came to the conclusion not only that this thing which you found in the blood was the cause of the disease, but that the tsetse fly was the cause of its being deposited in the animal in each case?—That, of course, is a matter of experiment.

14302. And then you ascertained that?—Yes.

14303. I thought that nagana was a disease which did not necessarily occur in what is called a fly-belt?—All diseases are apt to burst over their bounds. Once in ten years or so, on account of some question of temperature or dryness of the country, the wild animals accompanied by the flies spread out over the country up the valleys in order to get moister places for grass and water, and therefore every 10, 15 or 20 years the fly disease is apt, as it were, to burst out and spread 50 or 60 miles from the fly country.

14304. It follows the wild animals wherever they go?—These flies live on the wild animals, and follow them wherever they go. If the wild animals cannot get sufficient food and water in the fly country they spread over the surrounding country.

14305. (*Mr. Ram.*) Are the wild animals made ill by the presence of these flies?—No.

14306. (*Chairman.*) Were any experiments made on animals, beyond those of which you have told us, for the purpose of discovering the cause of nagana? Did you make any preparation from them?—No, those organisms will not live outside the body on the ordinary media then in use. It is quite a different thing from a bacterium; it is an animal parasite, and at that time there was no idea of its being cultivated outside the body.

14307. The tsetse fly, I suppose, draws blood from the animal which it attacks?—Yes. In regard to animal experimentation, as I said, first of all there is the small foreign-looking thing found in the blood of cattle in very small numbers; you could not say that it had anything to do with the disease; but when you put a quantity of the blood into dogs and horses you found that this body pressed very much to the front. Then you found out by accident that the animals coming from the tsetse fly country have this trypanosome in their blood. The natives thought that the tsetse fly disease was caused by eating the vegetation in these unhealthy places, especially where there was wild game. So, in order to experiment further, I sent down horses into this fly country for a certain time, muzzled in such a way that they could not eat or drink anything. They were taken down in the morning, brought back at night, and not allowed to drink water or eat a blade of grass. The horses which were sent down in this way came back to the top of the hill and developed the same parasite in their blood.

14308. (*Sir Mackenzie Chalmers.*) They were sent down in the morning, and brought back in the evening?—Yes, and invariably we found this trypanosome in their blood, and in three weeks or so they died of this disease. Then, naturally, one began to think that the tsetse fly had something to do with it, because the flies were biting them when they were down there, and one began experimenting by bringing up these flies in cages, feeding them on a dog suffering from nagana, and then at various times afterwards feeding them on healthy animals, after twelve, twenty-four, forty-eight, and sixty hours, and so on. Thus I discovered that this fly could carry this trypanosome from an infected animal to a healthy animal readily up to forty-eight hours; so that one could see in the case of the animals going down to the fly country, and being bitten, that if they were bitten by flies even forty-eight hours after they had fed on an infected animal, it might give rise to the disease. Then another question arose: Were the flies themselves, as you found them in the fly country, capable of giving rise to this disease without any feeding on infected animals up above? Accordingly, I brought up cages full of these tsetse flies to the top of the hill, and put them straightway on healthy animals, and the healthy animals all got the same disease. Therefore, the fly down in the fly country was infected with this parasite, and could give it to any domestic animal that came near.

14309. (*Chairman.*) A fly, do you mean, that was not a tsetse fly?—No, only the tsetse fly.

14310. I thought you said the common or garden fly. You meant the common tsetse fly?—Yes. I meant the ordinary tsetse fly as found in the bush and not artificially infected. Then one naturally wondered where these things got this little parasite from, and, in order to find that out further experiments were made. The flies feed, of course, upon the wild animals; what more natural then than that they got this parasite from the wild animals? The wild animals are perfectly healthy looking and sleek, and do not appear to be suffering from anything. Accordingly, I went down and shot many wild animals, buffaloes, koodoos, wildebeeste and others, and the moment an animal was killed I sent up a bottle full of its blood to the top of the hill, where there was no nagana at the time, and injected that blood into healthy dogs. A certain number of these dogs took nagana, and I found this same parasite in their blood. In this way I showed that these wild animals had this thing in their blood; and afterwards, to make this more sure, by microscopic examination of the blood of the wild animals, and by patiently looking for a long time microscopically at the blood of these wild animals, I discovered the thing itself in their blood, in small numbers, of course; in large numbers it would affect their health. In small numbers, so far as I know, it does not affect their health. So that there, again, by animal experimentation, it was proved that the wild animals act as a reservoir of this particular parasite, and I do not see how one could have proved it otherwise. Even when one knew that the parasite was in the blood, it took a whole day of examination of very many specimens to find a single parasite with the microscope; and one would not have examined so

long and so carefully unless one knew that one would find it if one had patience.

14311. It helped to ascertain the cause of the disease?—I think that animal experimentation helped in everything.

14312. Has it helped you at all at present to discover any remedy?—It was in 1895 I sent home a dog suffering from nagana to London, which dog arrived here alive; that is to say, as one dog died another was inoculated, and at last a dog was delivered in London with this living trypanosome in its blood, and these trypanosomes have been spread from London from that one dog to scientific workers all over the world, and there has been an enormous amount of work done in the last ten or twelve years with regard to these trypanosomes. There have been, I should say, thousands of animal experiments with a view to find a method of serum treatment, and quite an extraordinary number of experiments have been made to find a method of medicinal treatment: and, as you know from the daily press, within the last few days there has been discovered a powerful drug, one injection of which, for example, into a guinea-pig which is just dying of this disease, which would not have ten minutes to live (I do not think I am exaggerating), which is at death's door, will drive all the trypanosomes out of its blood, and in a day or two that animal will appear healthy, and animals so treated have remained without trypanosomes in their blood for, I think, two months.

14313. What is the drug?—That is not published yet, so I will not mention the name; but another drug which has been used very much is a drug which is called atoxyl, an arsenical preparation.

14314. (*Sir Mackenzie Chalmers.*) That is a dangerous preparation, is it not—dangerous to patients, sometimes?—M. Nicolle, of the Pasteur Institute, said that he thought it might be dangerous by accumulating in the system, but I do not think there is any proof that with care there is danger to human beings. Koch has been to Uganda, and in the last few months has been using it on many thousands of natives, as far as I am aware, without any fatal results.

14315. (*Chairman.*) I understand that you are not specially engaged in the discovery of remedies at present?—I am on the Royal Society's Committee for the discovery of a drug to cure sleeping sickness.

14316. I presume that in almost every case the discovery of the cause of a disease is the first step towards the discovery of a remedy for that disease?—Yes.

14317. And, to that extent, at any rate, you think you have got on to assured ground with regard to nagana?—In regard to these trypanosomes, certainly. Sleeping sickness is another disease of the same kind.

14318. Do you think that progress is being made towards recovery and remedy by means of experiments on animals?—Yes. I never dreamed that we would be able in time to cure an animal of trypanosomiasis. It is a very difficult question, and one does not want to say anything decided, the matter being still *sub judice*. When I was in Zululand, in 1894 and 1895, I tried arsenic on horses affected by nagana, and I was able to keep those horses alive for a year by giving them arsenic in their food. As a rule, horses die in about three weeks of this acute disease. Of course, during that year I thought I had a method of curing horses of this very fatal disease. But at the end of the year the trypanosomes came back into the blood, and, although one doubled or trebled the dose of arsenic in the animal's food, the trypanosomes paid no longer any attention to the arsenic, but multiplied and killed the animal, and in that condition our knowledge has remained till within the last year or two. Lately a great deal of work has been done, especially in regard to sleeping sickness, and now the idea is that by giving an arsenical preparation first, and killing all those parasites that are susceptible to arsenic, you can kill off the remainder by giving them another poison. The poison used has been, first, atoxyl, and then a preparation of mercury, and no doubt Mr. Plummer has kept animals alive in this way for some 300 days. These rats ought to die in five days. The Liverpool School of Tropical Medicine have got much the same result. It is a question whether we can say that these animals are really cured; but, however sceptical I may be, I imagine that when a rat lives 300 days instead of five, it looks very much like a cure.

14319. (*Sir William Collins.*) These are all chemical agencies to which you refer, not sera?—Purely drugs, just like quinine in malaria. The parasite in sleeping sickness and nagana is an animal parasite closely related to the malarial parasite. It is much more delicate than a bacterium. If you put it on this table it would die in a few minutes; if you put the *micrococcus melitensis* on the table, it would live for months. The one is much more delicate and much more easily got at by drugs. These protozoal parasites are more easily affected by drugs given by the mouth than are bacteria.

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.
5 Nov. 1907.

14320. (*Dr. Gaskell.*) They are supposed to be mere animal parasites, and the others are supposed to be vegetable parasites?—Yes.

14321. (*Chairman.*) There is something you can tell us about experiment with sleeping sickness. You, I believe, went out to Africa to study the disease?—I went out to Uganda in the beginning of 1903. Up to that time there had been a certain amount of work done on sleeping sickness, especially by the Portuguese, who sent out a Commission to the West Coast of Africa. The result of their work was the belief that sleeping sickness is caused by a certain streptococcus, one of these vegetable parasites belonging to the same class as the micrococcus melitensis. When I arrived in Uganda, the Royal Society's Commission had been at work for about a year, and the conclusion they had also come to was that this disease was caused by this bacterium. I found one member of the Commission still there, and in the course of conversation he told me that on five occasions he had seen a different kind of parasite in the sleeping sickness patients, namely, one of the trypanosomes. Trypanosomes by this time, of course, had become well known, and on the West Coast of Africa they had been found in the blood of man. These parasites had been named Trypanosoma Gambiense, and cases of this disease had been sent home to England. Curiously, it was never dreamt that this trypanosoma fever, as it was called, had any relation to sleeping sickness; so that when this man in Uganda mentioned to me that he had seen on several occasions trypanosomes in sleeping sickness, he said that it was curious that this trypanosoma fever extended into the interior of Africa, and he also, like the others, had no idea that the trypanosoma had any causal connection with sleeping sickness. Now, on account of my old work in Zululand, having worked at a trypanosome disease for two years, I was naturally very interested in this observation of his, and I said to him—If you will wait a few weeks longer (he was going to England at the time) I will examine cases with you on the hypothesis that this trypanosoma may really be the cause of the disease.

14322. You mean that you would examine cases of people with sleeping sickness?—Yes. So he remained for three weeks longer, during which time we examined some 30 cases of sleeping sickness for trypanosomes, and for trypanosomes alone. I simply wanted to find out in how many cases one could find trypanosomes.

14323. Taking blood from them, do you mean?—No, in that case we took the cerebro-spinal fluid.

14324. After death?—No, during life. We gave the natives chloroform, and removed about an ounce of fluid from the vertebral canal, and had it centrifuged in order to throw any little solid bodies down to the bottom. I examined the sediment, and in most of these cases we found the trypanosome. In fact, after this man left, and I went into the thing more carefully, this trypanosome was found in the cerebro-spinal fluid in every case of sleeping sickness examined. Now, the moment one finds a parasite occurring in 100 per cent. of a particular disease, one begins to think it may have something to do with it. Of course, it is no proof that, because you find it in 100 per cent., it is the cause of the disease, but still it is a hopeful beginning. I put aside the idea of sleeping sickness being caused by a bacterium, and went for the trypanosome. After finding it in 100 per cent. in the cerebro-spinal fluid, we went on to examine the blood. Just as in the cattle in nagana the trypanosomes are exceedingly scarce in the blood in sleeping sickness; and it is only by very patient work and examining large quantities of blood that you can find them. In this way we found this same trypanosome in every case in the blood, except on one occasion. So we had now learned the fact that in the blood of sleeping-sickness cases, and in the cerebro-spinal fluid, we could always find this parasite. The next point we investigated was this. If this parasite is an ordinary harmless guest of the people of this country, then it will be found in the natives who live outside the sleeping sickness area, as well as in those

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.

5 Nov. 1907.

who live within this area. Just as in nagana you have a fly country, so in sleeping sickness you have a sleeping sickness area, outside which the natives will not suffer from sleeping sickness. So we examined some 200 cases of natives from a region outside the sleeping sickness area, and we could not find this parasite in a single case.

14325. Examining in the blood?—Yes. We examined the blood in the same careful way that we examined the sleeping sickness blood, and in not a single case could we find the parasite. Then it began to look as if this trypanosome had really something to do with the disease. Accordingly we took cerebro-spinal fluid containing these living creatures, and injected this fluid into the ordinary animals we found round about. The monkey, of course, is very common there, and so are dogs and cattle. I had taken out some guinea-pigs and rabbits, and so we injected this parasite into all these animals and awaited results.

14326. Did you consider that the sleeping sickness must be caused by some bacillus or coccus in the cerebro-spinal fluid?—I thought, of course, that it must be caused by some living organism, because when you have a so-called infectious disease attacking large masses of men it is probably caused by a living organism.

14327. It was only in the place where you looked for it? You spoke first of having examined the cerebro-spinal fluid?—The principal symptoms in sleeping sickness are nerve symptoms, and you would naturally make a careful examination of the nervous system.

14328. You had expected to find traces of it there?—Yes. Just as Pasteur, in hydrophobia, went to the brain of the animals to find the virus, so when an animal is suffering from a nervous disease you go to the nervous system.

14329. It was the symptoms that induced you to look there?—Yes, the symptoms are purely nervous symptoms. To return to the injected monkeys. The blood of these monkeys was examined every day, and their temperature was taken very carefully, and they were watched. After five or six days the same trypanosome appeared in their blood, and we found it daily for some time. Sleeping sickness is a very slow, chronic disease, and at the end of three, four, and five months these monkeys began to show the same kind of symptoms that men show; they became very lethargic, and sat all day, as it were, with their heads on their knees, apparently asleep, and in the course of time these monkeys died. Then, on some occasions, we examined the cerebro-spinal fluid of a monkey during life, but it is difficult matter to examine the cerebro-spinal fluid of such a small animal; after death we examined the cerebro-spinal fluid, and we found this trypanosome in it as we had found it in the blood. In man there is a particular change in the brain, first described by Dr. Mott, so that if you cut a section of the brain you can tell by the appearance of it that he has died from sleeping sickness. If these monkeys died of the same disease, you would naturally expect to find this peculiar anatomical change of the brain. This anatomical change of the brain was found first, I believe, by Captain, Harvey, R.A.M.C. And therefore the conclusion has been come to that the disease of which the monkeys died is the same as the disease in man, and that in all probability the trypanosome is the cause.

14330. (*Sir William Collins.*) Is that change always found in the monkeys?—No, not nearly always, because the monkeys die much more quickly than man, and this change is only found in the chronic cases.

14331. (*Chairman.*) Only found in man, do you mean, in the long chronic cases?—It is only found in the monkey in those cases which last a long time. It is a very slow, chronic change which takes place. The monkey dies in three or four months, and man dies it may be in three or four years. The length of time the poison has been acting brings about these chronic changes in the brain; whereas if a man dies in the early stages of the disease, or if a monkey dies after three months, neither of them will show this peculiar anatomical change.

14332. (*Sir Mackenzie Chalmers.*) For instance, if a man infected with sleeping sickness was killed accidentally three or four months afterwards, you would not expect to find this particular anatomical change?—No, I do not think that it would be found after an illness of only three or four months.

14333. (*Sir William Collins.*) Are these microscopical changes that you allude to often absent in the brain of monkeys that are subjected to the disease?—Yes.

14334. (*Sir Mackenzie Chalmers.*) If the disease runs its normal course you usually find this microscopical changes?—Yes, it is a difficult matter, of course, making this particular observation, and in Uganda it was not done very often; but the examination was made for the Commission in London.

14335. (*Sir William Collins.*) It was found by Dr. Mott, was it not?—Yes, and the cases in which he found it were usually chronic cases. We sent him specimens of every brain we examined in Uganda, so that he had a great deal of material to work on during this investigation. We did not cultivate these trypanosomes outside the body, as was done in the case of Malta fever, so that the proof is not as good. You may inject into a monkey cerebro-spinal fluid, which you know to contain a certain living thing, but it may also contain something else, so that the proof is not as complete as in the case of a bacterium which you can grow outside the body, and then inject into a susceptible animal. The growth of the trypanosome outside the body of sleeping sickness has never been accomplished. But when you have done a number of experiments of this kind; when you find the same parasite in every case of the disease; when you find it giving rise to the disease in animals, you come to the conclusion that in all probability you are dealing with the right thing. Then the next point to investigate was how are these natives infected, and, from my old work on nagana, I at once thonght that a tsetse fly would be the carrier of the trypanosome. At that time it was not known that there were any tsetse flies in Uganda, but when we went down to the lake shore and began to hunt for them we found a particular species of tsetse fly, different from the nagana one present, and in large numbers. We caught these flies, kept them in cages, fed them on sleeping sickness natives, and then on healthy monkeys, and we found that these tsetse flies could carry sleeping sickness from a sick native to a healthy monkey. And then we made the further experiment. As there were a great number of infected natives on the lake shore, we collected these flies from among these natives, brought them up to the laboratory, and put them straightway on healthy monkeys, and we found that these monkeys took the disease. Then the next thing we did was to investigate the distribution of the disease. The distribution of sleeping sickness in Uganda is very extraordinary. It is confined to a narrow belt running along the margin of the Lake Victoria and its islands. Further, the disease is only found where there are forests. You do not find sleeping sickness where grass plains came down to the shore. You find no sleeping sickness if there is a belt of papyrus reeds growing along the lake shore. In the interior of the country there is no sleeping sickness. It is a very peculiar distribution. Therefore, I said to myself, if this tsetse fly carries it, very probably this fly has also a peculiar distribution. The tsetse fly which carries nagana is spread all over the country. Then we got hold of the native chiefs, and they set their minor chiefs all over Uganda to collect flies, and within a couple of months they sent in about a thousand collections of flies from all over the country. At the same time, we asked them to send in a word as to whether sleeping sickness was found where the flies were found. Then we separated all these biting flies into two categories, namely, this particular tsetse fly and the others, and we took two large maps, and whenever a collection of flies came in from a place containing one or more of these tsetse flies we put a red mark on that spot on the map. We also had another map of the same size, and if a chief reported that sleeping sickness was found at a particular place, we put a red mark on the same place on the second map. This went on for some months, until at last we had about a thousand observations, and then, when you looked at the two maps, you found that the red spots on one map coincided with the red spots on the other map, and the blue discs which we put on the places where no tsetse flies were found coincided exactly with the places where no sleeping sickness was found. Accordingly, we came to the conclusion that the distributions of sleeping sickness and of this particular species of tsetse fly were identical, and that gave us another proof that this trypanosome was the cause of the disease, and that there was only one way by which

man could become infected, and that by being exposed to the bites of this particular species of tsetse fly. Since then a good deal of work has been done, but that is now, I think, established beyond doubt.

14336. (*Chairman.*) From what quarter did the tsetse fly get it in order to convey it to man?—I think in Uganda the principal reservoir is man himself.

14337. From man to man?—From man to man.

14338. (*Sir Mackenzie Chalmers.*) Carried by the fly?—Yes.

14339. (*Chairman.*) In Africa, then, the tsetse fly bites mankind?—Yes; I think they all bite man. All the flies we worked with were caught on men. The tsetse fly gives the sleeping sickness trypanosome to man, but it does not give the nagana trypanosome to man.

14340. (*Sir Mackenzie Chalmers.*) The tsetse fly of nagana feeds on man and on animals, but man is not susceptible to the disease. It does not live in man's blood. The trypanosome of nagana is communicated to man, but does not affect him?—That is so; it dies off; it does not live in his blood.

14341. Do you find the trypanosome in the body of the tsetse fly itself?—Of course, if you examine the blood from the stomach of a tsetse fly, naturally if it has fed upon an animal containing trypanosomes, you find them there quite readily, and you find them there for some five days; it takes about five days for the full feed of blood to disappear altogether from the stomach, and as long as there is any remnant of blood in the stomach you may find the trypanosome.

14342. Do you know at all the mechanism by which the tsetse fly communicates the trypanosome from itself into the wound that it makes in man?—No; I believe it is by simple mechanical transference. There may be a more complicated mechanism behind. All that we have been able to discover up to the present time is that in the proboscis, which is a well-marked tube (I have examined thousands of these probosces), up to forty-eight hours after feeding on an infected animal, you can often see living trypanosomes. Whether they wriggled up from the stomach, or whether there was any other mechanism by which they got, as it were, from the blood, or whether they simply remained there after feeding, is not known, and it is rather difficult to find out. But let us suppose there is a living trypanosome in that tube. Now, when the fly thrusts that tube into a new animal, it injects a certain amount of fluid. This is the cause of the inflammation of the part—it is the cause of the greater supply of blood to the part, just like the sting of a gnat. If, then, you have a tube with a living trypanosome in it, and the fly squirts down it a quantity of fluid, in all probability the living trypanosome will be thrown into the blood of the attacked animal, and when it is there it at once begins to multiply.

14343. The trypanosome inoculates you, in fact?—Yes, the tsetse fly inoculates you with the trypanosome.

14344. (*Mr. Ram.*) Is there any way of accounting for the distribution of this fly in Uganda? You spoke of its distribution as being very curious?—It is a very curious distribution, but it is very difficult to arrive at the reasons in nature for the peculiar distribution of animals. You will find on one hillside in England one particular species of butterfly, which you will not find in any other place. I do not know that any person can give the reason for that. Sometimes you may have a theory, but it is difficult to find the true reason. In this particular case they evidently depend upon the presence of clear water. We do not know anything in their natural history which would make them depend upon clear water.

14345. They are always found in the company of clear water?—Yes, if you have a river full of reeds, a marshy river, which is a common kind of river in Uganda, the fly never goes up there; it requires a river which has always lots of water in it; it must have forest and clear water; it will not live in grass alongside water; it will not live in a banana plantation alongside water. It lives where there are tall trees and jungle and clear water. Koch says, or is reported to have said, that they live on crocodiles principally, and that may be the reason for their distribution.

14346. (*Sir Mackenzie Chalmers.*) How far away do they fly?—In Uganda I do not think they are found, as a rule, more than 150 yards away.

14347. (*Dr. Gaskell.*) The jungle must be close to water?—Yes.

14348. So that if you cleared away all the jungle close to water you would clear away the fly?—Yes.

14349. That is being done at Entebbe, is it not?—Yes, and at ferries, and such-like places.

14350. (*Chairman.*) You have told us that you used experiments on monkeys for the purpose of finding this trypanosome and identifying it as the cause of the disease, and I understand that you also used experiments on monkeys for the purpose of testing whether the tsetse fly was the distributor?—Yes.

14351. Do you consider that those experiments were necessary in order to make the discoveries which you believe you have made?—I think so. It would be very difficult to imagine any way of proving that the tsetse fly carries the disease unless you have an animal to experiment with. You could not do it on man, and after finding the trypanosome in the cerebro-spinal fluid and in the blood of man, you would have stuck—you could not have gone a step further. It was only by using the monkey in place of a man that you could prove that this thing did give rise to a disease, which was similar to sleeping sickness, and also that the flies feeding upon the natives on the lake shore could give the disease to a monkey. Further, it would be difficult to prove that flies fed on a sleeping sickness patient could give rise to the disease in healthy monkeys unless you used animal experimentation. I do not think you could have gone any further than the mere discovery.

14352. You were first set on inquiry about the capacity of the tsetse fly by the recollection of what had happened with the tsetse fly in nagana?—Yes.

14353. And having done that and looking upon it as a suspicious individual, then you got the chiefs to give you this information in regard to the distribution of the flies?—Yes.

14354. That was not a matter of animal experiment?—No.

14355. That seems to have satisfied your mind that the tsetse fly did convey the disease?—Yes.

14356. So that so far you may have used experiments as confirmatory of your theory about the tsetse fly, but you were almost morally certain, before you made those experiments, that the tsetse fly was the distributor?—These animal experiments were made to begin with; the chiefs were called in after the experimental work had been done. Of course, there were no more experiments made on the monkeys than were supposed to be necessary to prove that the trypanosome was the cause of sleeping sickness.

14357. I was mistaken. I thought your experiments to find the distributor of the trypanosome had been subsequent to your giving these instructions to the chiefs?—No.

14358. You gave those instructions in consequence of finding the trypanosome in the tsetse fly?—In consequence of finding that this tsetse fly could convey this trypanosome to healthy animals. The next point was to find out why the distribution of sleeping sickness was so peculiar.

14359. Do you think that in regard to this sleeping sickness as in regard to nagana, the animal experiments were valuable and essential to confirm your discovery?—Yes, I think so.

14360. As to remedies, you have not gone into that in regard to sleeping sickness?—There has, of course, been an enormous amount of work done on sleeping sickness in regard to remedies, but I have not done any.

14361. I understand that you have not made a special study of remedies?—No. Not in sleeping sickness.

14362. I think we shall have another gentleman from Liverpool who has done so.

14363. (*Sir William Collins.*) I should like to ask you a few questions to supplement your very interesting evidence. In the first place, as regards the experiments that you have made in these various researches and experiments, should I be right in thinking that they were very painful experiments?—No, none of these experiments were painful. Most of them were done by a hypodermic needle being inserted into the skin, and a small quantity of fluid injected.

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.

5 Nov. 1907.

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.

Nov. 1907.

14364. I rather gathered that you would tell us that your experiments were mostly confined to punctures with the hypodermic needle—drawing blood, feeding experiments, and so forth?—Yes.

14365. Was there anything more painful than that?—I do not think so.

14366. And would the result in the animals in which there were pathogenic results be painful illnesses?—No, I do not think so. In the case of Malta fever most of the monkeys recover after a week or two of fever. A small percentage of them die, and, of course, they must have a disagreeable feeling due to the high temperature, and those who recover may have a chronic disease as in man, lasting for some months. I dare say they may have symptoms of arthritis, slight swelling of the joints, and that kind of thing, just as in man, but I would not say that in the monkey there was what you would call an agonising or even painful disease.

14367. Have any of your experiments necessitated the performance of anything like surgical operations upon animals of any extensive character?—No, I have not been associated with many experiments of that kind. I worked with Wright at one time on the leucocytes of the blood. We made a few experiments on placing a canula in the thoracic duct of dogs and removing a certain amount of fluid for the purpose of examining it; and I have also performed a few operations, such as removing the spleen of dogs, to find out what effect it would have upon the leucocytes of the blood; but those were all done under chloroform, and the dogs were killed after the thoracic fluid was drawn off. I do not think that any experiments, in the performance of which I have been associated, have been what one would call painful experiments.

14368. I understood you to say that as the result of your experiments with Malta fever you claimed that you had been led to a system of prevention of that disease, on what you call broad lines rather than on serum lines?—Yes.

14369. Would you tell me exactly what you mean by that?—If, after a great deal of work, you discovered a serum which would immunise a man against Malta fever, you would require to inject each of the men several times with the serum, and that would be what I call narrow lines. If you give an order that no goat's milk is to be used in the Army or in the Navy, and you stop the disease at one blow, like cutting off the head of a snake, I call those broad lines.

14370. I thought that was what you had in your mind. When you claimed to have saved the garrison and the Navy, it was by the method of stopping certain articles of food, not by methods of vaccinating or inoculating?—That is so.

14371. (*Sir Mackenzie Chalmers.*) Or medicine, or cure?—Yes, that is the kind of way of stopping disease I like to aim at always.

14372. Prevention?—Yes, it is far better.

14373. (*Sir William Collins.*) I think it has been called the stamping out and stamping in method?—Yes; stamping out.

14374. Has an attempt been made to prepare a serum against Malta fever?—Yes, and it has up to the present failed. Eyre, in this country, tried to prepare a serum from the horse, but his conclusion was that the serum was of very little use.

14375. Did it sometimes produce rather alarming symptoms?—I did not see the experiments, and I do not know. You will find his paper in the reports of the Royal Society on Mediterranean fever, but I do not think he gives any alarming results in that paper. I do not think there were any alarming results; they were merely experiments made on guinea-pigs.

14376. On page 120 of Part VI. of the Reports of the Mediterranean Fever Commission I find that he speaks of the disquieting results recorded by Lieutenant Bousfield?—Is that serum or inoculation fluid?

14377. That is in the Report of the Commission?—Was Bousfield working with serum or with inoculation fluid?

14378. It is under the heading of "Sequelæ of Inoculations"?—Those are very different things; the one is the serum of an animal immunised against the disease; the other is simply dead bacilli injected under the skin of a man to bring about the same sort of changes in a minor degree that the man would get by having the disease itself.

14379. My question was rather whether any of the methods, which you spoke of as narrow lines, had resulted in any disquieting symptoms?—I do not think so. The method of immunising by an injection of the dead *micrococcus melitensis* has been tried to some extent; that is to say, Wright has tried it, Bassett Smith, of Haslar Hospital, tried it as a curative agent, and several others; and we tried it in Malta, but up to the present I should say with very little result indeed, either as a curative or as an immunising agent.

14380. You compared the mortality of Malta fever with that of typhoid, and I understood you to say that although Malta fever was relatively rarely fatal, it caused a prolonged amount of suffering and ill-health; but could you give us some proportion as to the case mortality of Malta fever as against that of typhoid?—I do not suppose that the mortality of Malta fever exceeds 2 per cent., as a rule; whereas, of course, in typhoid you may have 10, 15, or 20 per cent.

14381. In the pamphlet which you have handed in you give the total admissions of Malta fever, simple continued fever, and enteric fever among the troops from 1897 to 1906, and you call attention to a drop in the Malta fever admissions from 1905 to 1906 of considerable magnitude; is that not so?—The preventive measures came into being on the 1st of July, 1906, and it was after that that there was a big drop in the number of cases.

14382. Then, during the first half of 1906 were there no preventive measures at work?—No.

14383. Could you complete the figures for 1906, because these are only to the end of October, and if the preventive measures began on the 1st July, and you give the figures only to the end of October, that would only cover a very short period?—I have not got the figures with me. We have them in the office, of course. But I have the figures for 1907. You must remember that when you start preventive measures of this kind naturally there are a number of men who are sickening, as it were, for the disease. The incubation period of Malta fever is probably in some cases long—a month or two months, it is supposed—a man may be carrying the micrococcus without evincing the disease, so that after you begin your preventive measures you expect, of course, a certain number of cases to occur for some time to come. Accordingly, in that Chart 2, in July there are still a number of cases—there are ten cases, which gives an annual ratio of 18.6. In the chart from 1899 to 1905, in July there are 235 cases in the seven years, giving a ratio of 47.8. In July, 1905, there were 77 cases.

14384. I was confining my question to Table I. on page 4. There you see that the total admissions of Malta fever in 1905 were 643?—Yes, that is the same chart as Chart 2, on page 10.

14385. I daresay. Then the figures there given for 1906 to the end of October are 147. I understand from you that the preventive measures began on July 1st, 1906?—Yes.

14386. I was anxious to know whether you could complete the figures to the end of the year 1906, or whether you can say that the drop from 643 in 1905 to 147 in 1906 to the end of October could be attributed wholly or in part to the preventive measures, seeing that they did not begin, I understand, until the 1st of July?—In 1905 the total admissions of continued fever were 1906.

14387. I am speaking of Malta fever?—Of Malta fever there were in 1905, 643, and in 1906, up to the end of October, 147.

14388. But do not you see that there was a great fall from 643 cases in 1905 to 147 down to the end of October, 1906? I understand from you that the preventive measures began on the 1st of July?—Yes.

14389. So that, really, during the first half of the year 1906 those preventive measures could not have been operative?—In the first half of 1906 there may have been preventive measures to some little extent, because the thing was getting known, but it was only about the beginning of July that the order came out that no goats' milk was to be used under any circumstances whatever. It would be tinned milk in the year before that they had been using, or milk that they tried to boil or sterilise.

14390. But in order scientifically to attribute a particular fall of a disease to some particular cause, it is necessary to eliminate other causes which might have been at work, is it not?—Yes. But I think this thing is so clear, and so clearly dependent upon the

milk, that I shall be obliged if you can show me any fallacy.

14391. Then will you tell me, do you think that the whole drop in admissions of Malta fever from 643 in 1905 to 147 down to the end of October, 1906, is attributable to those preventive measures?—Yes.

14392. Although I understand you to tell me that those preventive measures did not begin until the 1st of July?—Yes.

14393. (*Dr. Gaskell.*) Have you not stated, on page 11 of your pamphlet, that in July, August, and September, 1905, there were 258 cases, whereas in the same months of 1906 the numbers fell to 26?—Yes, and I have said that the preventive measures only came into use about the beginning of July, 1906, and the remarkable diminution is at once seen.

14394. (*Sir William Collins.*) I will not trouble you further on that point. If you would still look at that table on page 4, you will see there is a great drop in admissions of continued fever in the same period from 1905 to the first ten months in 1906 from 1,199 to 462. To what do you attribute the fall in simple continued fever; would that also be due to the preventive measures that you adopted?—Yes. Simple continued fever is one of those vague terms in which is probably included a number of mild cases of Malta fever, and also mild cases of enteric, so that anything which would lessen the cases of Malta fever or lessen the cases of enteric fever would have an effect upon the number of cases returned of simple continued fever.

14395. Does the same answer apply to the next column, where the enteric fever fell from 64 to 9?—To answer your question categorically, I should say no, because enteric fever is a more definite entity than simple continued fever; but it also is a difficult fever to diagnose from Malta fever. When I went out to Malta first, every severe case of Malta fever was called enteric, and all the milder cases were called remittent; so that, doubtless, in spite of the excellent diagnoses made by medical officers of the British Army, cases of Malta fever do get returned as enteric in spite of all the care that is taken, because the symptoms of the two diseases are the same for some time. I daresay that a man with experience at the end of either of the two diseases would give a very accurate guess whether it had been Malta fever or enteric; the longer duration of the one, perhaps, and these arthritic pains and swellings of the joints in a well-marked case, would help to make the diagnosis, but people with less experience are very apt to say: "This must be enteric; the man has a black tongue, high temperature, and a little delirium"; and it is diagnosed as enteric. And it is a difficult matter, as you know, to change the names of diseases in the Army. There is a certain amount of changing names in books and that sort of thing involved, and in many cases I daresay the diagnosis remains, and that might account, to some little extent, for that nine among the enteric fever.

14396. You think that the preventive measures in respect of the prohibition of milk put in force in July, 1906, are responsible for the drop in all these cases of Malta fever, simple continued fever, and enteric fever from 1905 down to the end of the first ten months of 1906?—Why not? Enteric fever is very often carried by milk. If you blot out the chief cause of Malta fever—namely, milk—you will also make a difference in enteric fever, because you must remember that as the Malta water supply is beyond reproach, enteric fever would be carried by flies contaminating milk, and that kind of thing, I should say, frequently. We did not investigate into enteric fever, but if you blot out the whole of Malta fever you will make a difference in simple continued fever and enteric.

14397. You blot it all out?—If you blot out the whole Malta fever.

14398. Do you mean that there is so much error in diagnosis that the whole typhoid will disappear if these measures are put in force with regard to Malta?—No, I do not think so. I do not think that enteric is carried only by goats' milk. I imagine that a fair percentage of enteric fever is caused in Malta by milk, and if you blot out all goats' milk, and only use condensed milk, say from Switzerland, in tins, you will blot out a certain amount of enteric, but you will not blot it all out, because enteric does not depend altogether, I should say, on milk. In fact, we do not know all the routes by which enteric is carried. I should be very happy to work at that most important question, but enteric fever has never been subjected to as searching an investigation as this Malta fever; and at the present time we do not know exactly how enteric fever is carried, especially in different parts of the world. In England you have often water-borne enteric, or you have an epidemic when it is milk-borne. In India you may have an epidemic where you cannot say it is from water or milk, but you must go in for some other theory, such as contamination of food by flies. In enteric fever it is fairly unknown as to how the infection is carried from one case to another.

14399. (*Sir Mackenzie Chalmers.*) There are probably many channels in England?—Yes, probably.

14400. (*Sir William Collins.*) With regard to the special case to which you called our attention, of the "Joshua Nicholson," and the goat's milk on board ship, the full story is told, is it not, in Part VII. of the Reports to which you have already alluded?—Yes, by Staff-Surgeon Clayton, R.N.

14401. Did I rightly understand that all the crew of the "Joshua Nicholson" were affected?—No, there were several of the crew who were not affected, so far as one can make out. It is all written at very great length by Clayton, and I think the general result that is brought out is that the men who drank that milk in any quantity got the fever.

14402. What happened to the goats at Antwerp?—We have everything that is known about the matter in that paper. We know where the goats were kept; they were kept in some kind of enclosure in Antwerp; but we failed to trace any fever cases in Antwerp, and we failed to trace any cases of fever between Antwerp and America.

14403. I just wanted the story completed. I think that is so?—It is all put in that paper, so far as I remember, but that is my impression. We could not follow these cases any further; we could not get hold of the people after the goats left the "Joshua Nicholson."

14404. I find that at Antwerp: "The staff of the quarantine station and many individuals in the neighbourhood are said to have partaken of the milk, both raw and boiled, during the five days the goats were interned here, but no information can be obtained of the subsequent occurrence of cases of illness resembling Mediterranean fever." And, further, "The s.s 'St. Andrew' carried 30 cattlemen and the three goat herds, and Mr. Thompson, in addition to a crew of 30 men. Most of these drank of the milk, but the master of the ship and also his owners state that none of the men suffered from any illness"?—The captain of a sea-going ship is often not very desirous of giving information; it may give him trouble, and that kind of thing. As a matter of fact, any person reading the history of that "St. Nicholas" epidemic cannot come to any conclusion but that it was the milk of the goats that caused it, and because there are hiatuses in the story that does not, so far as I can see, weaken that evidence. If you take 30 monkeys, and give them all one drink of milk containing these micrococci, and the great majority of them take Malta fever, I think that is pretty conclusive. A judgment is formed, as a rule, not from one fact but from several. There are a series of arguments that come and affect your mind, and in the end you have a certain opinion. My opinion is absolutely fixed that the goats' milk gives Malta fever, as I think I have made clear to the Commission.

14405. Am I right in saying that recently, in the "Times" of September 12th, some attempt was made to pluck the laurels from your crown in regard to this discovery?—There was a letter written by a retired officer of our own corps, but he is a well-known gentleman in our corps, and I was the unfortunate means of breaking him about two years ago. I was sent out to Barbadoes, where things were not going on well, and the result of my inquiry was that he was put on the sick list, and sent home, and left the service; so that anything which he would say about me I should say must be received with caution.

14406. Was not the claim put forward by Colonel Fitzpatrick that Captain Hughes was the discoverer?—Yes.

14407. Yes. I only wanted to give you an opportunity of stating it. The claim made on behalf of

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.

5 Nov. 1907.

Captain Hughes was that he had priority in regard to the discovery which you have announced to the Commission of the goats' milk as the cause of Mediterranean fever. Is that not so?—Yes.

14408. To what did Captain Hughes attribute the Malta fever? He worked greatly at it and published a work on the subject?—Yes, he published a large work on the subject. He attributed it to effluvia from drains.

14409. I think his words were: "A specific micrococcus emanating during hot weather from a saprophytic existence in soil polluted with the fæces and urine of those suffering from the same disease"?—Yes, that is the danger of a scientific man, instead of using experiments, going in for theory and speculation.

14410. Do you say that Captain Hughes did not make experiments on animals?—He made a few—some one or two experiments, and he did not do much good.

14411. Should I be wrong in saying that Captain Hughes made many experiments on animals?—I do not know that he made many; I think he only made a few.

14412. Have you seen his book?—I knew him very well. He was a pupil of mine at Netley.

14413. He is no longer living?—No. Captain Hughes was a great friend of mine, and I speak with great respect of him; but he had not that particular stamp of mind which we call the scientific mind. He was not able as it were to distinguish very clearly between speculation and fact. As a matter of fact, his book, which is a large book, does not contain a single sentence which advances our knowledge of this particular disease. He was very industrious and a very nice fellow indeed, but he had not that particular thing which the gods give a man to enable him to do scientific work—investigation work—advancement of knowledge work.

14414. Did Dr. Allan McFadyean possess that rare gift?—I do not know his work very well.

14415. Did he not fall a victim to inoculation in the laboratory with typhoid and Malta fever?—He is said to have died of Malta fever on account of experimenting with it in the laboratory.

14416. Was any serum used in his case?—I do not know. He had been working, of course, for years at typhoid inoculation.

14417. At the Lister Institute?—Yes.

14418. In regard to nagana, do I rightly understand that in your opinion the trypanosome is transferred by the tsetse fly from wild animals to domesticated animals?—It must be so, I think.

14419. And that in wild animals it appears to be non-pathogenic?—So far as we know it is non-pathogenic.

14420. But in domesticated animals it is pathogenic?—In certain domesticated animals.

14421. And in man is it pathogenic?—I have never seen a case in man.

14422. That would point, would it not, to the great importance of the influence of soil upon the seed that you implant in it?—By soil you mean the human blood and tissues?

14423. Yes?—If you put it in that way, of course, but you can only put these things boldly. One animal is susceptible to the disease, and another animal is not. The house mouse is susceptible to anthrax, the field mouse is not. The two animals look very much the same; with any chemical analysis or microscopical examination you cannot see any difference between the blood and tissues of the two animals, but one is susceptible and the other is not. It is a part of Nature that is too hidden for us to be able to examine with our limited intelligence.

14424. Then as regards sleeping sickness, I think you mentioned that before the discovery of the trypanosome, a claim had been set up for a streptococcus as the cause?—Yes, by the Portuguese, and by the first Royal Society's Commission.

14425. That was very stoutly supported at one time, was it not?—I never believed in it.

14426. Did not Castellani support it?—I was a Fellow of the Royal Society and a member of the Sleeping Sickness Committee when his paper came home giving this coccus as the cause, and I said to the committee that there was absolutely nothing in the paper which amounted to anything like proof. It wanted animal experimentation. I wondered why he had not been able to give this sleeping sickness, by means of his particular coccus, to some animal. He showed no signs of ever having tried to do so.

14427. Were no experiments performed by the Portuguese Commission?—I think so, but I must say that I have not read the Report of that Commission very thoroughly, because it is written in Portuguese.

14428. And did they point to this streptococcus as the cause?—Yes. Castellani also pointed to it.

14429. And Castellani afterwards changed his mind, did he not?—He changed his mind after I wrote my paper.

14430. No doubt the influence of the divine gift?—In that particular case I should say that it was great luck my having worked for two years at a similar disease. I gave Castellani the paper describing the observations made by us during the three weeks he remained in Uganda after my arrival. I gave him that paper to take with him to London, in order that he should not go back empty-handed. In the interests of scientific history he ought to have associated my name with his, or at least described in the text the part I took, but he did neither.

14431. You point out the importance of differentiating and avoiding fallacies. I am anxious to know whether, besides this streptococcus, there was not at one time another cause asserted very strongly, and held by a great many as the cause of sleeping sickness?—*Filaria perstans* was one.

14432. It was found in a negro in London?—Yes, I think so.

14433. And then found in many others?—I should say, judging from the natives that I had to deal with in Uganda, that if you looked sufficiently long you would find it in 100 per cent., in the same number as you find the trypanosome, showing the difficulty of distinguishing between two parasites. The one is evidently a harmless parasite, living in the blood of man, just as Nagana trypanosomes live in the blood of wild animals. Here you have a parasite, and 100 per cent. of the natives have it in their blood.

14434. Healthy natives?—No, many of these natives had sleeping sickness, and we used to find the *perstans* in them almost as regularly as the trypanosome.

14435. Was it also found in healthy natives, and in the Indians in America?—Yes, and it is found also in natives living outside the sleeping sickness areas, and in certain sleeping sickness areas where there was no *perstans* found, the trypanosome was found.

14436. Do you know Sir Patrick Manson's work on tropical diseases?—Yes.

14437. He says: "In dealing with newly-discovered parasites, our experience with *Filaria perstans* should serve as a warning against precipitancy in drawing conclusions from the mere fact of concurrence." Do you agree with that?—Certainly.

14438. And he says: "Moreover, what we already know about some African trypanosomes should also make us hesitate in definitely committing ourselves to a trypanosome as the cause of sleeping sickness." You do not agree with that?—Well, you see, I look upon Sir Patrick Manson as what we call an armchair naturalist. He lives here in London, and is very clever at reading papers and prophesying what is going to happen, but he has not the practical knowledge; he does not go and work at the thing practically on the spot; and if a man is going to write a text book he cannot expect every word in the text book to be true, or even to be fairly reasonably true. There must be a lot of padding and nonsense in a text book. A text book is the lowest form of literature that I know of.

14439. I take it that you do not agree with Sir Patrick Manson when he says: "Experimental evidence, therefore, so valuable in the settlement of such questions, has in this matter, to say the least of it, been far from conclusive." That is referring to sleeping sickness?—Is that five or six years ago?

14440. It is the year before last?—I was opening a discussion on sleeping sickness some three years ago in Oxford, at the meeting there of the British Medical Association, and I quoted Sir Patrick Manson on sleeping sickness, he having opened a discussion on the same question, I think, the year before. I put down all the conclusions that he had come to, and I said:

"Every conclusion of a year ago is now proved to be false except one, and that is that medicinal treatment has no effect." Unfortunately, that still remains true. All the other conclusions were absolutely wrong. I put down in the same way, under separate headings, some ten or twelve statements, and I asked the British Medical Association to bring these up a few years later, and find out how many of them remained true. I think at the present time all mine remain true.

14441. How long ago was that?—1904, three years ago.

14442. What about the medical treatment? Does not Koch claim that a subcutaneous injection of arsenic is beneficial?—Yes, but Robert Koch is getting an old man, and he is much frequented by interviewers, and it is very difficult to get an interviewer to repeat exactly what you say.

14443. You do not accept the crocodile?—No, I do not, and I do not think Koch himself does. He has never himself said that atoxyl will cure. He said that he had every faith in it, and so he gave the lay mind to understand that he was curing them by the hundred, but I have never believed it, and I do not think that any person who knows the subject has believed it; and I think he has gone back to Berlin very disappointed that the atoxyl treatment has been useless.

14444. You think that attention should be directed rather to destroying the haunts of the tsetse fly than to an onslaught on the crocodile?—That is the broad way. I think myself that in a place like Uganda, especially after the population has been so reduced, if the Government and the chiefs made a big effort, they could take the whole of the natives out of the sleeping sickness areas, and put them in healthy places, and if they could do that, theoretically in forty-eight hours there would be no more sleeping sickness; there would be no fresh cases of sleeping sickness in Uganda. The tsetse fly only carries infection for forty-eight hours, and if you could remove the reservoir of the disease, in forty-eight hours every Glossina palpalis in Uganda would be harmless, and if you did not expose affected people to the tsetse fly again, then sleeping sickness would be blotted out by a wave of the magician's wand sort of business.

14445. If you were made plenipotentiary there would be no fear of its spreading in East Africa or down the Congo or the Nile; is that so?—It is mainly a question of money. If you know the distribution of the fly, and you know the natural history of the disease, you can do a great deal. The great thing in all these cases is to know the natural history from beginning to end, and not till then to try to do anything. You require to keep the people away from the sleeping sickness areas until the healthy-looking ones have developed the disease; you require to keep them away in the interior of the country. Those who are affected by sleeping sickness must, of course, never go back to the fly area. If at the end of forty-eight hours you sent back the population to the lake shore you would not be able to distinguish between the healthy and the unhealthy; you would therefore require to keep the sleeping sickness area population away from the tsetse fly for several months.

14446. (*Mr. Ram.*) You must give the fly perfectly healthy food for forty-eight hours?—You must give it either healthy food or none at all. At the end of forty-eight hours it is harmless.

14447. Those whom it had infected might again go on and develop the disease afterwards?—Certainly, after, let us say, six months.

14448. Affording unwholesome food again at the end of the six months?—Yes; you require to keep the place clear for some time, but I think at the present time it is not out of practical politics to keep the fly area of Uganda clear of population for a certain time. The Uganda natives are docile, and their chiefs are intelligent, energetic people, so that I would not look upon it now as outside practical politics to stamp out sleeping sickness in Uganda.

14449. (*Sir Mackenzie Chalmers.*) Does Sir Patrick Manson still hold the opinion that sleeping sickness is not due to a trypanosome, or has he altered his mind in any way, do you know?—I should say he has altered his mind.

14450. At any rate, his opinion at that time was one of scepticism. He thought it might be due to a trypanosome, or it might be due to other causes. Was that it?—It is impossible for me to say.

14451. You do not know how far he had studied the subject at the time when he gave out these dicta?—I do not know.

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.

5 Nov. 1907.

14452. May I take it generally that, in your opinion, without experiments on animals you could not have discovered the cause of Malta fever, and that without experiments on animals it would have been a mere chance if you had attributed Malta fever to the milk of the goat. Would you go so far as that, or not?—Yes. As I said before, it would be an accident. Two epidemiologists were sent out to Malta to work at it, from the statistical standpoint, but they both failed. Perhaps, if a third had attacked the question, the third might have succeeded. But I say that the other way is the proper and reasonable way.

14453. It is not only the proper way, but it is the way that you pursued, and it was by means of animal experimentation that you came to these conclusions as to the cause of Malta fever?—Certainly.

14454. I am not sure that we have them, but can you give us the figures at all for 1907. Do you know what the effect of stopping the milk has been in 1907?—Yes, certainly. I put these figures down here, because it is very striking. I saw the Director-General of the Navy a few days ago, and he told me that they had not had a single case in the Navy this year.

14455. What about the soldiers?—Among the soldiers we had two cases in January, two in February, one in March, one in April, one in May, two in June, none in July or August, and only one in September; that is ten cases. These are the official figures, but I have received private information from Malta showing that at least 3 of these of these are readmissions; deducting these, therefore, there have been 7 cases this year.

14456. Can you give me the total for the same months in the year before?—From January to September, 1906, there were 151 cases.

14457. Then take from January to July, 1905 and 1906—I should like to get the three years. Perhaps you can give it later on?—From January to September, 1905, there were 538 cases among the soldiers alone.

14458. Can you also give us the corresponding months for 1905?—I have not got that here, but will supply it. No change has taken place in the incidence of this fever among the native population in Malta this year; it is not a particular year.

14459. The soldiers and sailors having been deprived of goats' milk, you have this curious fall in the incidence of Malta fever?—Yes.

14460. There have been a few cases amongst the sailors in 1907?—Yes, there have been 10 cases, or, deducting readmissions, 7.

14461. But there have been 7 or 8 cases tabulated as Malta fever?—Yes.

14462. It is always possible, I suppose, that those soldiers in the town may have access to goats' milk?—It is impossible to prevent their getting it, because in those small public-houses soldiers very often have egg-flip, a glass of milk with some brandy in it. It is rather a common thing if they are out late at night.

14463. Apart from stopping the supply of goats' milk to them as soldiers, have they been forbidden in any way to touch milk in Malta?—They have been lectured a great deal on the subject.

14464. Do you yourself attribute the few cases that have happened this year to the probability of milk infection?—Certainly. Some of the cases which have occurred this year are distinctly returned as being due to the drinking of milk.

14465. There are conceivably, I suppose, other ways? You say, for instance, that the micrococcus is excreted with the urine?—Yes.

14466. Is it possible that there could be contamination in that way; for instance, in the case of drying urine, you might get it through the air?—We held that theory for some time rather strongly.

14467. But you have no evidence in support of it?—We could not get any evidence in support of it—not in nature. If you grossly contaminate dust with the *micrococcus melitensis*, and blow it about a room in which a monkey is living, you will give the monkey the disease; but the Commission never could give the disease by blowing dust gathered from natural positions, say, in the neighbourhood of urinals, or from fever wards, or places which might be contaminated. Major Horrocks, R.A.M.C., a member of the Commission, made many experiments on these lines. He

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.

5 Nov. 1907.

never got any evidence in favour of the dust theory except under artificial conditions. And naturally if you take billions of micrococci, and mix them with a small quantity of dust, it is like feeding an animal; it gets its tongue all covered and its food all covered; it is like a feeding experiment; so I do not think infection by dust takes place once in 1,000 times. We cannot tell, of course, but there is no proof that dust causes the disease.

14468. So that, so far as you know, the disease is communicated purely by food, and not by inhalation?—Purely by food.

14469. Possibly you inhale the micrococcus, and it gets destroyed in the lungs?—If you inhale sufficient then that would be a feeding experiment, because it sticks in the mucous membrane of the nose and mouth and is swallowed. But no doubt if the micrococci reached the lungs they would be absorbed into the circulation and not destroyed.

14470. But before the disease germinates it has to get to the alimentary canal?—No, it gets from the alimentary canal into the blood, and it grows in the tissues and especially in the spleen. There is no evidence that it grows when it is in the alimentary canal.

14471. Where does it start?—It is such a small thing that it may be absorbed by the mucous membrane of the tonsils. In my opinion, it may be absorbed by any mucous membrane.

14472. It starts into the blood, you say?—The moment it gets into the lymphatic system it passes, probably, from there to the blood, and from there to the different organs, settles down in the spleen, and grows there, and gives rise to a certain poison, and so on.

14473. May we take it generally that if remedies are to be found for those diseases experiments must be made on animals before they are made on man?—Certainly.

14474. For instance, when a toxyl was suggested as a remedy, was it tried first on animals or first on man?—You ought to have Professor Cushny here to answer that. He is a pharmacologist. I do not know the history of drugs in that way.

14475. You have not studied these tropical diseases with reference to medicinal remedies yourself?—I have done a certain amount. I tried, for example, arsenic and other drugs on nagana when I was in Zululand, and I tried without success many drugs on Malta fever. I did not try any medicinal treatment on sleeping sickness, because I was only in Uganda seven months.

14476. You were investigating merely the cause, and not the treatment?—Yes. The Commission afterwards, of course, did try different remedies, especially, I think, Captain Grieg, I.M.S., Captain Gray, R.A.M.C., and Lieut. Pollock, R.A.M.C.

14477. Were you a member of any Plague Commission?—I am a member of the Plague Committee of the India Office at present.

14478. Have you at all considered the Reports of that Commission as to the transmission of plague by rat fleas?—Yes.

14479. And in your opinion is it established that the rat flea is the ordinary mode of transmission of plague from animal to man, and from man to man?—Yes, that is my opinion distinctly. The ultimate proof, of course, the giving it to man, cannot be made, but except for that every step in the proof has been taken.

14480. Have those conclusions been arrived at by experiments with animals?—Absolutely.

14481. Could you have arrived at those conclusions without experiments with animals?—Certainly not.

14482. And, so far, by means of that knowledge, are we put on the right lines in the way of prevention of plague?—Certainly.

14483. (*Mr. Ram.*) If I gathered aright from you you discovered this *micrococcus melitensis* in 1888?—1886. I think the report was published in 1887 for the first time.

14484. There was no Commission until 1906?—1904. It lasted for about three years.

14485. Was anything being done in all these years to attempt to find out the cause of Malta fever or to stop it?—Captain Hughes worked from about 1893 to 1897, and I should say that he worked at the fever, but was unsuccessful in discovering the true cause; and, as you can see from the statistics, nothing was done to practically limit the cases. That is to say, Malta fever cases were getting more numerous in the Army and Navy up to the year of the Commission, and it was on account of that probably that the Commission was formed.

14486. Is there any cows' milk at Malta?—Very little.

14487. There are some cows kept there, are there not?—Yes.

14488. Have any experiments been made with regard to their milk?—Yes.

14489. Has it been found to be free from the *micrococcus melitensis*.—No, there was a suspicion that some of the cattle were affected. I do not remember whether it was actually found in the milk, but there was some suspicion that some of the cattle were affected by Malta fever.

14490. You have told us that there has been almost an entire elimination of the disease from the Army and Navy now. Have you any statistics to show that the native population are still as subject to Malta fever as they were previously?—I have a letter from Dr. Zammit, who is a member of the Board of Health, and he informs me that the number of cases of Malta fever in the native population is as great this year as ever.

14491. The goat continues to be used for milk?—Yes, absolutely. The Government have been able to do very little yet. Malta is a very conservative place.

14492. The evidence now seems to be that the *micrococcus melitensis* is swallowed; that the contamination is given to man by swallowing the micrococcus?—The infection is taken by swallowing.

14493. And you have almost eliminated the idea of dust and that sort of thing being the cause?—Yes, I think so, or mosquitos. The mosquito theory was also strongly held for some time, but we could not get any proof of the mosquito being the carrier.

14494. You were asked one or two questions about sera. You have not done much with sera yourself?—No, very little.

14495. As I understand, when you found animals useful, and, indeed, necessary, was when you were anxious to discover what the particular micrococcus was that was the cause of this disease. And was it by experiments upon animals that you were able to discover it, to the elimination of other micrococci that might be present?—What I meant was, that in investigating a disease, the important thing is to be able to state definitely that you are quite sure that a particular organism is the cause of the disease, and it is often very difficult to be absolutely able to say this unless you have an opportunity of animal experimentation.

14496. When you find that a particular organism does produce certain symptoms, and is followed invariably by certain symptoms, you arrive at the conclusion that that is the cause of that particular disease, and in order to test it you want to try it on different animals to see the result of your different experiments. Is that where the use of animals comes in?—Yes, that is one use.

14497. That is one. Further, when the disease has been established, and you are anxious to know the cause of the disease, do you then inoculate animals with the blood or other secretion of a person known to be diseased in order to see the effect upon that animal?—I do not think, as a matter of practical work, that that is very often done. You mean for purely diagnostic purposes?

14498. I want to get it accurately from you, if you can say exactly where it is that experiments on animals come in to be useful. I think I have got one instance that you explained in your examination-in-chief very accurately. I am not sure that I follow the second one as accurately. You spoke about taking the serum from some infected patient, and inoculating animals with it. Why did you inoculate these animals; to see what?—I do not remember that I did say that I took sera from any particular man and put it into an animal.

14499. I thought you said that from a good many natives you took their blood?—From wild animals in Nagana.

14500. But you took the blood of natives in sleeping sickness in different parts of the country, some parts where there was sleeping sickness and some parts where there was not?—I only examined it through the microscope.

14501. You did not experiment on animals?—No, that was purely microscopical examination; we found by microscopical examination of the cerebro-spinal fluid and the blood of sleeping sickness patients that practically in 100 per cent. we could find this particular parasite. We then took 200 people from a part of the country outside the sleeping sickness area, and examined their blood in the same way—not the cerebro-spinal fluid in that case, but only the blood, and we found it in none of them. If you will only consider for a moment, that is a very strong argument in favour of the trypanosome being the cause of sleeping sickness. That was the beginning of the work. You must remember that we were under the disadvantage of believing that this trypanosome was well known, and that it was the cause of a disease called trypanosoma fever, which was supposed to be quite distinct from sleeping sickness. On account of that, we had to work, as it were, against the difficulty of a preconceived notion—we had to get rid of that—and it was only by these experiments that we gradually lost the preconceived idea, and took on the new one.

14502. (*Sir Mackenzie Chalmers.*) Did you ever inoculate an animal with the blood of a person suffering from sleeping sickness and containing trypanosomes?—Yes, on many occasions. First, we had to find out if monkeys would take the disease.

14503. With the result that, having inoculated the monkey with the blood of a person containing trypanosomes, sleeping sickness was produced?—Yes, that was an experiment to help to prove that the parasite is the cause of the disease.

14504. (*Dr. Gaskell.*) Could you tell us at all how the Malta fever spreads, or the *micrococcus melitensis* spreads, from goat to goat?—No. We know that if we put into a small space a certain number of affected goats, and a certain number of healthy goats, after a certain time some of these healthy goats will be found to be affected by the disease by close contact of that kind. If you put a healthy monkey and an affected monkey together, so that they feed out of the same dish, and the urine may contaminate their food, if you keep the affected monkey and the healthy monkey together for some time, you find that the healthy monkey gets the disease; but if you keep them separate from each other, so that they can only touch each other, and the urine of one cannot get at the food of the other, then they do not take the disease.

14505. There is one question that I wanted you to make clear to the Commission, and that was that in these cases of bacterial infection, bacterial disease, one of the important points is to inject a particular bacillus or micrococcus into an animal in order to see that it gets that disease. Is not that so?—Yes.

14506. When you do that, do you not inject both the fluid substance and the bacteria—you inject both?—Yes.

14507. Then it is open, is it not, for people to say that the disease was caused by the fluid substance rather than by the bacillus?—That is the reason why we try to cultivate the bacilli outside the body for several generations on a neutral substance.

14508. You also mentioned another point, I think, which I want to bring out, and that was the Chamberlain or Pasteur filter?—Yes, that is merely to separate the solid particles from the fluid.

14509. Does it effectually separate the microbe from the fluid in which the microbe is contained?—As a rule, yes. You can take a fluid containing millions or billions of bacteria—say typhoid bacilli—and filter that fluid through a Chamberlain filter, and not a single bacillus will come through. The fluid that comes through will be absolutely sterile.

14510. And what is the effect of injecting that fluid that comes through into an animal?—It may give rise to a temporary rise of temperature. There may be a little poison in it, there may be a few toxins of the bacteria in the fluid, and that would give rise to a temporary rise of temperature and a feeling of seediness, but it would not give rise to the disease itself.

14511. Whereas, injecting the microbes, on the other side of the filter, would give rise to the disease?—Yes, if the animal is susceptible.

14512. I think it has been tried again and again, and we may take it as proved, may we?—Yes, I think you may take it as proved. There are some toxins, of course, so powerful that a little filtrate without any bacteria will kill animals, but it kills them as strychnine kills them.

14513. It would not necessarily give the kind of disease you were investigating?—No. Tetanus, for example, is a very powerful poison in that way.

Colonel D. Bruce, C.B., F.R.S. R.A.M.C.

5 Nov. 1907.

14514. In these cases of sleeping sickness in monkeys, and also in man, do you think there is much pain when the animal is suffering from that sickness?—I think man may suffer at first to some extent from headache and from a feeling of uneasiness, but I do not think he ever feels much pain. I think in a very few cases, say 1 per cent., acute symptoms of mania may come on on account of the poison affecting the brain, and that, I should say, was very uncomfortable. I mean to say that the patient is in a constant state of restlessness, talking, laughing and throwing himself about, and sleepless, but I do not think there is any pain. With regard to monkeys, I do not think there is any pain at all, at least so far as one can see.

14515. They always go into a lethargic condition?—They get into an absolutely lethargic condition; they feel nothing.

14516. Do they waste very much?—No; man does not waste as a rule; he remains quite plump to the end.

14517. We have had a picture shown us here in the Commission of a dog that was infected with sleeping sickness, with the trypanosome, at Khartoum. It appeared in a very emaciated condition, and it was suggested that this dog had been in terrible pain in consequence of the disease. I was wondering whether you could say that that was likely or not to be the case. There was emaciation there undoubtedly?—I do not think that sleeping sickness trypanosome would cause emaciation in a dog, and I am quite sure, from all I have seen of dogs inoculated with the sleeping sickness, that they did not suffer at all. They are very refractory to the disease. But was it certain that this dog had sleeping sickness? I should imagine that it was one of the other trypanosome diseases.

14518. (*Dr. Wilson.*) You admit that this disease, Malta fever, is very widely distributed?—Yes.

14519. And you contend that its mode of propagation is entirely through drinking goats' milk?—Yes, in Malta we think it is; probably in 999 cases out of a thousand. These are only figures which are not worth anything, of course, merely figurative; but we feel sure that most cases of Malta fever are caused by drinking goats' milk, but we cannot assert that for the rest of the world. The evidence up to the present time is that where there is Malta fever there is a grave suspicion of goats being at the bottom of it—in the Punjaub and in South Africa.

14520. Do you refer to Maltese goats entirely?—I do not think that the Maltese goat has found its way to the Punjaub. I think there is certainly a suspicion that the Maltese goat finds its way to South Africa, because if they want to improve the breed of goat you send to Malta for some of the Maltese goats.

14521. Then you would only put this as the probable mode of propagation—not a certain mode. You would not say that it is the absolute sole mode of propagation?—In Malta I should say that it was almost the only mode of propagation. I cannot speak for places that I do not know anything about. I have a strong suspicion that the goat is mixed up with it everywhere.

14522. But is not this microbial fever, because you call it a microbial fever, very singular in this respect, that you have the micro-organism excreted by an apparently healthy animal, and it produces all these febrile symptoms when taken in food?—By man do you mean?

14523. Yes?—Yes. There is nothing very singular about it, because the one animal is less susceptible than the other. A goat does not suffer from fever and inconvenience by taking this thing inside it. Man does. But the micrococcus can live in the goat, and, curiously enough, it finds its way after a time into the mammary glands. It is killed out in the spleen, killed out in the kidneys, killed out in the liver, killed out in the blood; but it gets into the mammary glands, and remains there and multiplies for years.

14524. But is the mammary gland in a diseased condition; have you found it so at all?—I am now thinking of tubercle bacilli in cows milk. In the Maltese goat you have a very highly developed mammary gland, developed beyond all nature, and it is, as it were, the place of least resistance. There must be some reason for it, but I put it broadly, only that here you have a gland developed out of all proportion, a gland that almost touches the ground when the animal walks

Colonel D. Bruce, C.B., F.R.S., R.A.M.C.

5 Nov. 1907.

along—a huge over-developed gland. You can imagine that an over-developed gland of that sort would have tissues of less resistance than ordinary normal sized and normal glands. Therefore it is that in the Maltese goat the *micrococcus melitensis* is killed out of all the other organs, and remains in the mammary gland chronic, and established, so far as we can see, for years.

14525. Do the glands and teats show any signs of disease?—No, you cannot tell by examining a goat that is has Malta fever.

14526. So that they entirely differ from the tuberculous glands in the cow, for example?—Yes. The tubercle, of course, forms nodules, and the *micrococcus melitensis* does not form any nodules; it does not form any tumour formation, as it were, because the little nodules of tubercle are like little tumours.

14527. When you were out in South Africa, had you opportunities for personally inquiring into the effects of anti-typhoid inoculation during the South African War?—I have had a good deal to do with it. I wrote a report upon the subject for the Government which caused anti-typhoid inoculation to be stopped for the time being, because I did not think it was being done sufficiently carefully, and with sufficient forethought.

14528. Do you think it is of value as a preventive?—We—that is, the Royal Army Medical Corps, and especially Colonel Leishman, Captains Harrison, Grattan and Kennedy—are working at it just now, and we are getting good results, but I would not like to say at present whether it will be found of great practical use in practice. We had a very good example the other day (I do not know whether you know of it, but it is a beautiful example) in the 17th Lancers. Every regiment going out to an enteric area is carefully inoculated before it leaves this country, inoculated twice, with this anti-typhoid fluid. The 17th Lancers were inoculated, went straight out to India, and fell straightway into an epidemic of enteric. There were 63 cases in that regiment; 62 of these occurred among the non-inoculated, and only one among the inoculated, and that one case had only been inoculated once instead of twice—the man refused to have the second inoculation. These men were all living together under the same conditions, with the same food, and the same everything, and yet that was the result. That, of course, is a beautiful result. But then you see the men were inoculated twice a very short time before they became exposed to the poison, and we do not know yet how long this immunity will last. There is no doubt that there is a certain amount of immunity attained in plague, cholera, and typhoid by injecting the dead bacilli under the skin. It imitates the disease to a certain extent. The disease of typhoid fever is caused by the typhoid bacillus, and the fever and general effect are caused by the poisons excreted by the bacilli, and also held up in the bodies of the bacilli. So that if you insert 50 millions or so of these bacilli under the skin, and they all dissolve up, that man gets a dose of typhoid poison just as he would if he had typhoid fever, only in a smaller extent. Therefore it seems to me quite natural that these inoculations of dead bacilli should bring about a certain amount of immunity.

14529. Has not Strong, while working in the Philippines, stated that he does not believe in the dead bacilli, and has taken to inject living bacilli?—That was in plague. If you heat typhoid bacilli to 65 degrees Centigrade in order to kill them you destroy the toxin that causes the immunity; you therefore kill them at as low a temperature as possible, 53 degrees, or thereabouts, and then do not get the same effect as with the living bacillus. Haffkine used the living cholera bacillus when he started. And certainly if we could use the living typhoid bacillus it would be better, but he would be a bold man who would start anti-typhoid inoculation in the British army at the present moment with living typhoid bacilli.

THIRTY-THIRD DAY.

Wednesday, 6th November 1907.

MEMBERS PRESENT:

The Right Hon. the Viscount Selby (*Chairman*).

Sir W. S. Church, Bart., K.C.B., M.D.
Sir W. J. Collins, M.P., M.D., F.R.C.S.
Sir J. McFadyean, M.B.
Sir M. D. Chalmers, K.C.B., C.S.I.
Mr. A. J. Ram, K.C.
Mr. W. H. Gaskell, M.D., F.R.S.
Mr. G. Wilson, M.D., LL.D.
Captain C. Bigham, C.M.G. (*Secretary*).

Mr. George Granville Bantock, M.D., F.R.C.S.Ed., called in; and Examined.

Mr. George Granville Bantock, M.D., F.R.C.S.Ed.

6 Nov. 1907.

14530. (*Chairman.*) You are a Doctor of Medicine and a Fellow of the Royal College of Surgeons Edinburgh?—Yes.

14531. And you practice in London as a consulting surgeon?—That is so.

14532. And you are surgeon to the Samaritan Free Hospital for Women?—Consulting surgeon now.

14533. And a Founder and Fellow of the British Gynecological Society?—That is so.

14534. And a Fellow of the Obstetrical and other societies at home and abroad?—Yes.

14535. And you have practised a great deal and written a good deal, more particularly on abdominal surgery?—I have.

14536. And you have been asked to give evidence here by the chairman of the Parliamentary Anti-Vivisection Association?—Yes.

14537. I believe you are not a member of the Society?—I do not belong to any society.

14538. But you hold some views which affect the question of experiments on living animals which are well known, and that is the reason why you have been asked to come, I believe?—I think it is more particularly because of my views on bacteriology that I have been asked to give evidence, because I have never taken any active part in the question of vivisection, either for or against.

14539. I only said that you held some views which bore upon the question of experiments on animals?—It has some bearing.

14540. I understand your general view to be—I am going to take you through your evidence, of course—that bacteriologists are mistaken in the view that a great number of the most important diseases are proved to be due to the presence of a particular bacillus in the body?—I have a strong belief in that respect.

14541. And it would follow, I presume, that in your view all experiments upon animals made for the purpose of ascertaining and identifying the particular bacillus are useless?—For identifying the bacillus they may not be useless, that is to say, the bacillus may be characteristic of a particular condition; but my contention is that it is not the cause.

14542. You do not deny that it exists?—No, and it may be diagnostic of the condition, but I say that the bacillus is never the cause. My contention is that the bacillus is an accident of the disease—that is to say, it results from the disease, that the conditions are favourable for its development; for we are swarming with bacilli of various kinds, and it only wants certain conditions to favour the development of certain bacilli. That is the view I hold.

14543. I presume that if your view were adopted by physiologists generally they would be obliged to come to the opinion that a great many experiments which they at present make would be unnecessary?—I think so.

14544. Therefore I am only pointing out how in my view, and I fancy in yours, your view about bacteriology affects the question which we have to consider, which is as to how far experiments on animals are justifiable?—Undoubtedly.

14545-6. You are prepared to state to the Commission your views generally upon this subject?—Quite so. Like a good many other surgeons who had constantly to perform serious and delicate operations, I took a very keen interest in the system of what was called antiseptic surgery, which was introduced by the present Lord Lister some thirty-five years ago, and like them I tried it in my practice. The system was founded on the hypothesis that germs floating in the atmosphere fell into wounds, there developed and multiplied and produced all the evil effects which sometimes followed surgical operations. In order to combat these lamentable results this system, when it was fully exploited, included operating under an antiseptic spray,

and treating all instruments, ligatures and dressings on antiseptic lines. In the numerous operations which I had to perform, I soon found that the antiseptic (carbolic acid) spray had an injurious effect on the delicate lining membrane of the abdomen and other tissues, and I gradually began to reduce the strength of the solution until at last I used only ordinary London water to wash out or irrigate wounds, and finally depended on clean hands, instruments, ligatures and dressings, without the aid of antiseptics. In other words, I, in company with a very few other surgeons, dispensed with so-called antiseptics altogether as not only unnecessary but injurious, and I may be permitted to say that I took a not inconsiderable part in the somewhat acrimonious warfare which was aroused in the attack on Listerism by reading a paper on "Hyperpyrexia (or excessive rise of temperature) after Listerian Ovariotomy." In the course of my cross-examination I should like to elaborate that point, namely the results of my reading that paper at a society in London. As is well known, what is called antiseptic surgery, or Listerism, was ultimately discarded, and the system which was eventually adopted was the aseptic, which is the absolute negation of the antiseptic system. But aseptic surgery, which may be defined as clean surgery, is certainly not the outcome of bacteriological research, as many scientists and most people still blindly believe; but a commonsense revolt against the illogical details of surgical practice to which bacteriology gave rise. At the International Medical Congress, held in Berlin in 1891, Lord Lister acknowledged his error with a frankness which all must admire, though some, like myself, have difficulty in understanding the tenacity with which he has all along clung to the modern doctrine of bacteriology. In his address to that Congress Lord (then Sir Joseph) Lister spoke as follows in reference to surgical details in my own practice and in that of the late Mr. Lawson Tait. "Dr. Bantock, whose remarkable series of successful ovariotomies may seem to justify his practice does not, I believe, prepare his ligatures antiseptically. The success achieved by Bantock and Tait without, it is said, the use of antiseptic means, proves a stumbling block to some minds." No doubt, so long as they hold to the germ theory. "I can see that while the measures" (comprehended under the term cleanliness) "to which I have referred are, so far as they go, highly valuable, it must be in itself a very desirable thing to avoid the direct application to the peritoneum of strong and irritating antiseptic solutions." This latter is in itself a strong justification of my abandonment of carbolic acid. He continues: "As regards the spray, I feel ashamed that I should ever have recommended it for the purpose of destroying the microbes in the air. If we watch the formation of the spray and observe how its narrow initial cone expands as it advances with fresh portions of air continually drawn into its vortex, we see that many of the microbes in it, having only just come under its influence, cannot possibly have been deprived of their vitality. Yet there was a time when I assumed that such was the case, and trusting the spray implicitly, as an atmosphere free from living organisms, omitted various precautions which I had before supposed to be essential." He then describes how in a case of operation "the air passed freely in and out of the pleural cavity in a cloud of spray," and he arrives at the conclusion that "it is physically impossible that the microbes in such air can have been, in any way whatsoever, affected by their momentary presence in the air." "If then," he continues, "no harm resulted from the admission day after day of abundant atmospheric organisms to mingle unaltered with the serum in the pleural cavity, it seems to follow logically that the floating particles of the air may be disregarded in our surgical work, and if so we may dispense with antiseptic washing and irritation, provided always that we can trust ourselves and our assistants to avoid the introduction into the wound of septic defilement from other than atmospheric sources." What these sources are we learn from his address at Liverpool, in September, 1896, six years later. "'Hence I was led to conclude that it was the grosser forms of septic mischief rather than microbes in the attenuated condition in which they existed in the atmosphere that we had to dread in surgical practice." Here I may be permitted in passing to give expression to my admiration of the character of the man who can confess his error with such candour and honesty, seeing that such a confession of error must detract from the credence we should otherwise give to his later views. Would that his disciples were like minded! To proceed: What then are the "grosser forms of septic mischief"? "If," in the words of the late Dr. Campbell Black, "they are what is vulgarly called 'dirt,' then we are all agreed that to remove dirt (not, however, by killing it) and to keep wounds clean is perfectly scientific and proper treatment." What is this but the doctrine of "cleanliness," which I have advocated for so many years? Thus it will be seen that it only required that Lord Lister should have taken one step more to fall into line with me. For while he gave up the theory of atmospheric germs, he admitted that we may dispense with antiseptic washing and irrigation, and virtually came to accept the principle of cleanliness—one of the two principles in the enunciation of which I played no unimportant part, and which are now generally accepted in the case of ovariotomy. So much for antiseptic and aseptic surgery; and if I have alluded to this phase of the subject at some length, it is because I wish to dispel the belief, which is so persistently advanced, that aseptic surgery is the outcome of bacteriological research. Bacteriologists have long since discovered that in order to convert filth or dead organic matter of any kind into harmless constituents, Nature employs micro-organisms or microbes as her indispensable agents. Thus, in the modern septic tank, which is now so largely used in the treatment of sewage, it is the action of the micro-organisms, whether ærobic or anærobic, which dissolves the sewage, and it is the continuous action of these microbes which converts all manurial matter into the saline constituents which are essential for the nutrition of plant life. In the natural purification of filth-polluted streams, or in the conversion of dead animal or vegetable matter into the flora of the vegetable world, it is admitted that the micro-organism plays a beneficent part, and so I am prepared to contend that however these innumerable and infinitely minute vegetable organisms may be designated, they always play a more or less beneficent part when they are found to be associated with disease, and that, however characteristic any micro-organism may be of any particular form of infectious disease, it cannot be classed as pathogenic, in the sense that it is the actual agent causing the disease. The microbe in its relation to disease can only be regarded as a resultant or concomitant, and in that respect is of more or less value to the physician in assisting him to diagnose the form or kind of disease with which it is associated. But even in this respect there are abundant sources of error. For example, the bacteriologists themselves admit that there is frequently great difficulty in differentiating the tubercle bacillus from other bacilli belonging to allied groups or species, and the diphtheria or Loeffler's bacillus from the Hoffman or pseudo-bacillus. Again, the true Loeffler's bacillus is often found in healthy throats, and I may say also as a gynecologist that it is sometimes found in the generative passages of healthy women. On the other hand, in what may be termed to be undoubted cases of diphtheria (clinically) it is very often not found after continued and careful examination, and similar difficulties and uncertainties present themselves with regard to other so-called specific micro-organisms. Thus, the staphylococcus pyogenes and streplococcus pyogenes, which are supposed to cause suppuration, have been found by various observers in the vaginal discharges of healthy women, as also the bacillus coli communis and the bacillus typhosus. Dr. Stoker's well-known treatment of ulcerative conditions by oxygen gas incontestably proves that the stapbylococcus and streptococcus pyogenes were not only necessary for healthy granulation (or healing), but that any interference with them by means of germicides retarded the healing process. In several severe operations which have been performed by myself, and in which the healing process progressed satisfactorily, without any disquieting symptoms, I have had specimens of discharge examined by competent bacteriologists, and with one exception so-called pathogenic organisms were found to be present in all of them. Is it not, therefore, reasonable to conclude that these micro-organisms, while they may be necessary for processes of healing, are certainly not causative of disease? While it cannot be denied that there must be a virus or *materies morbi* to account for the spread of every communicable disease, I contend that another strong argument against their microbial origin is the fact that in respect to several of the most infectious

6 Nov. 1907.

diseases no specific micro-organism has yet been found, in spite of the most minute and persistent research. Thus, no specific or so-called pathogenic organism has been discovered in small-pox, vaccinia, measles, scarlet fever, whooping cough, or hydrophobia, and it seems very singular that the tetanus bacillus, which is believed to be the sole cause of tetanus or lockjaw should be found so abundantly in manured or garden soil, or on the surface of roads fouled here and there with horse-droppings. It is also worthy of note that in the disease for which microbal origin is claimed to have been most fully established, the pathogenic organism is usually associated with necrosis or death of tissue. Thus it is now generally admitted that the tubercle bacillus is not found in the sputum in the early stage of phthisis, but only when necrosis of the lung tissue sets in. The diphtheria bacillus, again, is associated with the septic or membranous throat, the typhoid bacillus with ulcerated intestine, the cholera vibrio with the inflamed intestinal canal, and the plague bacillus with the inflamed bubo or pneumonic lung. In all these instances is it not logical to conclude that these micro-organisms, instead of being pathogenic, are playing the part of nature's scavengers? On this point Dr. Vicentini says: "Considering the assimilating activity of bacteria on the one hand, and on the other their reducing activity at the expense of histological elements in decay, I have often asked myself whether this ubiquity of the bacterial elements is not, perhaps, destined to perform some important service, as, for instance, the expurgation of the fluids to act as scavengers in relation to decayed particles or cells of the body. The simple fact that bacteria are present in the products or morbid seats does not imply anything specific, so long as their totally extraneous origin and their quite independent entity be satisfactorily proved. Losing sight of this truth, as simple as it is essential, one risks falling into strange exaggerations, and is likely to include the most varied complaint (even the ingrowing nail, according to Regnault) in the list of bacteriological infections." In order to illustrate more fully my contention that so-called specific diseases have not a microbal origin, I will now deal with two of the diseases already named in which no specific micro-organism has been discovered—namely, small-pox and vaccinia—and two in which a specific organism is persistently paraded as the actual *causa causans* of the disease—namely, tuberculosis and diphtheria. With regard to the first two, I may here fitly quote from my pamphlet, to which I referred at the outset: "Investigators have, all the while, overlooked the fact that these diseases are due to a specific material poison which can be handled, and can be conveyed, from one subject to another, by inoculation. There is no mystery about this as there is about the natural mode of transmission—or should I not rather say propagation?—of these diseases, or of such diseases as typhus, typhoid, measles, scarlatina, etc. Take the case of small-pox, for instance. We know that if we insert an almost infinitesimal quantity of the contents of a small-pox vesicle, at the proper stage, under the skin of a perfectly healthy subject, an enormous multiplication of the poison takes place, as exhibited in the innumerable vesicles which appear on the surface of the body, each vesicle filled with a fluid possessing the same virulent properties as the original vesicle—in other words, an attack of small-pox, presumably under the influence of what we, in our ignorance, call a chemico-vital process. That this extraordinary state of things should be due to the action of a special form of bacillus passes one's comprehension and is incredible. It is not a mere local action, such as is attributed to the staphylococcus or streptococcus, when either of them is said to produce suppuration. It affects the whole constitution of the subject, and reminds one very forcibly of the effects produced by snake or other animal poison—which we know to be not the product of a bacillus, but of an organ specially constructed to that end. Vaccinia, under the same process, produces such a change in the constitution of the individual subjected to it, that, in at least a majority of cases and for an indefinite period of time, it renders that subject proof against the inoculation of itself and even of small-pox. And here I may be allowed to express the hope that my views will not meet with a "conscientious objection," but be examined dispassionately. What is the nature of this extraordinary change which is wrought in the constitution of an individual by an attack of small-pox, vaccinia, or other of the eruptive fevers, such as measles, scarlatina, etc., and which, in a large majority of cases, renders the subject insusceptible of a second attack? It is all a matter of conjecture, and, so far as I know, no one has offered even a plausible explanation. Is it a change in the actual constitution of the individual, or does it merely affect the nervous system only? Of the other two diseases I take the case of diphtheria first. This disease is said to be due to the influence of a specific bacillus—Loeffler's. How does it happen that this bacillus can be found in the throat of a subject weeks—yea, even months—after all trace of the disease has disappeared? This doctrine has suffered much discredit of late from the fact that this bacillus of Loeffler's is frequently present in some exanthemata (rash), and also in healthy persons. A still "more striking example is afforded in cases of tonsillotomy, wherein, upon the incised surface, a greyish membrane is formed, in which the bacilli abound without constitutional disturbance or any sign of diphtheria." I anticipate the argument that, if you allow some of the discharge from the throat of a subject of this disease to gain access to that of a presumably healthy individual, you *may*, but not necessarily, produce the disease in him. And you may point to a number of cases in which medical men, in the fulfilment of what they conceived to be their duty, have sacrificed their lives in the heroic attempt to succour their patients—as, for instance, in the course of the operation of tracheotomy. But the answer to this is the very valid one that you do not convey the bacilli only. You also convey the fluid in which they are bathed, in which I contend they live, and which, in my opinion, constitutes the real essence of the disease. As the vesicle in the case of variola (small-pox) and vaccinia is the outward manifestation of the disease and the contained fluid its essence, so in the case of diphtheria the condition of the throat is the outward manifestation, and the fluid oozing from its surface the essential element. Many observers of eminence and authority in this field concur in denying the connection of the Loeffler bacillus with diphtheria as cause and effect. I am bound to accept as matter of fact the statements made as to the association, even in a majority of cases, of the Loeffler bacillus with diphtheria, for they are not questioned; but to reverse the proposition, and say that their presence is the result of the disease, appears to me to be the more sound reasoning. The preceding argument appears to me to be unanswerable, and no one, as far as I know, has attempted to reply to it. But it will not be amiss to fortify it with some more *facts*. Thus Scharoz, writing in the "Deutsche Medicalische Woche," says: "There are certain cases which are clinically diphtheria, but in which the bacillus cannot be found." "It seems probable that widely distributed saprophytes, such as the bacillus, cannot alone be the cause of diphtheria." He quotes two cases in which diphtheria bacilli, so called, were obtained from wounds of the eye after cataract operations, in neither of which infection occurred. In a paper by Drs. Hewlett and Montagu Murray, published in the "British Medical Journal" on June 15th, 1901, the authors begin by saying that the purpose of their communication is to illustrate "the frequency with which children whose throats are presumably healthy may serve as sources of diphtheria," and, referring to appended tables, they continue: "It will be seen that the figures support two statements which are commonly made. The first statement is that the Klebs-Loeffler bacillus and pseudo-diphtheria bacillus exist in the throat in a large number of cases, especially in children, without producing any recognisable symptoms Out of 385 children under the age admitted for operation, or for some illness other than diphtheria, only 235 were free from both kinds of bacteria. In 92, or 24 per cent., the pseudo-diphtheria bacillus was found; in 58, or 15 per cent., the Klebs-Loeffler. Neglecting for the moment the presence of the pseudo-diphtheria bacillus, the pathogenic power of which is uncertain, these figures suggest that one out of every seven children, or at least one out of every seven sick children, is a possible source of diphtheria infection." They admit the possibility that "in some cases bacilli may have been present, but yet have escaped detection" (thereby underestimating the proportions), and "in view of this possibility it is interesting to note that in only seven of the cases was there any clinical evidence in favour of diphtheria, and that on the first examination in three of these cases no Klebs-Loeffler bacillus or pseudo-diphtheria bacillus was found in the throat." And one of "the morals deducible" from these figures "is that it is clear that babies and young children are not the harmless and innocent (*sic*) creatures usually imagined, and that kissing and other artificial

(*sic*) demonstrations of childish (*sic*) affection should be discouraged." I can imagine the effect such a recommendation by the family doctor would have upon a mother. Then they give "some of the results obtained by other observers with regard to the occurrence of the Klebs-Loeffler and pseudo-diphtheria bacilli in the throats of persons with no sign of diphtheria"; thus "Loeffler examined 160 healthy school children, of whom four showed diphtheria bacilli in their throats." "Park and Beebe, out of 330, 250 are described as children, healthy throats examined, in eight, virulent Klebs-Loeffler bacilli were present." "Rober has made an extensive series of observations upon the presence of diphtheria baccilli in the healthy throat. There were 128 persons examined, who had been in contact with cases of diphtheria, and 600 who had, not knowingly, been exposed to the disease. Of the 128 persons, the diphtheria bacillus was found in ten, a percentage of eight, and of the 600 persons it was found in fifteen, or 2.5 per cent." Under these circumstances what ground there is for regarding the pathogenic power of the one bacillus as certain, and that of the other as uncertain, does not appear. Coming now to tuberculosis, I will not dwell on Koch's "tuberculin fiasco," which was hailed by the profession as a panacea for tuberculosis, but it should be borne in mind that this fluid of Koch's was intended to kill the bacilli, but it was soon found that, in too many instances, it had the very opposite effect—of killing the patients—twenty-seven or twenty-eight in Berlin alone, according to Virchow, in the course of two or three months. It was shown that the injection of this fluid into a healthy subject produced little or no effect, but into a tuberculous subject it produced, in a few hours, what was called, a violent "reaction," and that this reaction was, in many cases, attended with the production of a fresh crop of tubercles, especially affecting the serous and mucous membranes. Virchow, speaking of these new eruptions after the injection of Koch's fluid, and resting on the assumption that "all tubercles are produced by bacilli," says of one particular case of pulmonary tuberculosis in which "the so-called pericardium" was affected, that "there was no alternative but to suppose that the germs had reached the place by way of metastasis. How could we help thinking of metastatic processes here, and conjecturing whether, in fact, the bacilli had not been mobilised, and whether they had not been diffused *through the body* by a process of infection? And since, as you know, Dr. Koch himself considers the bacilli to be sufficiently refractory to his remedy—*and we have not found that they are destroyed*—the possibility must not be overlooked," that, "by a process of softening, whereby the products of disintegration are rendered more fluid" this metastasis takes place. Does not this lend countenance to the doctrine I hold—viz., that the injection of the fluid is only so much added to the amount of the specific poison with which the system is impregnated, and that hence the bacilli are found in all parts of the body, following their food, as fish find their way into the overflow in cases of flood, or advance and recede with the tide? The acute symptoms which follow the injection of this fluid point clearly in this direction, as does their subsidence, so soon after, on the exhaustion of the supply, provided the dose be not a lethal one.

14547. Could you tell me what metastatic processes are?—The transference of disease from one part of the body to another. What, then, should be the remedy? This, viz., not to endeavour to destroy the bacilli, but to maintain the vital forces and processes at their highest state of efficiency, by providing such as are already possessed by, or are predisposed to, tuberculosis, with pure air, abundant light, nutritious food, and, in a word, all the conditions that tend to the maintenance of good health. This is actually the method now in vogue. But not because, as has been put into the mouth of the Marquess of Londonderry at the opening of a hospital for consumption, "the best germicide to kill off the microbe was to provide air, light, and sunshine," for we now know that these conditions favour their growth. I call attention to the fact that many cases of so-called tubercular peritonitis have been cured by opening the abdomen, and removing the fluid contained therein. I specially direct attention to the case of a young subject, aged sixteen, on whom I operated on March 25th, 1895. In making the incision through the thickened parietes, and just below the umbilicus, I cut through several deposits of cheesy matter, and exposed a brain-like tumour, several pounds in weight, involving the omentum. As it was impossible to entertain any idea of removing the tumour, I sponged out about a pint of fluid lying in the lower part of the abdominal cavity, and then closed the wound, two or three of the sutures involving these cheesy masses. The wound healed by first intention. Previous to the operation the patient was much emaciated, her hair was falling off, and she suffered from a peculiar form of diarrhœa with very offensive evacuations. I put her on an absolute milk diet, not sterilised, until the evacuations assumed a healthy character, and improvement set in so rapidly that she returned home on the 26th day. She is now in perfect health, well nourished, and with an abundant crop of hair, and all trace of the tumour and of the deposit in the parietes has disappeared. That this was an example of tubercular disease I have no doubt whatever, if we are to put our trust in macroscopical appearances and the attendant symptoms. Will some bacteriologist be good enough to explain these facts on the basis of the germ theory? It is a remarkable fact that this young lady scarcely ever tasted milk. Had she been in the habit of taking milk, being the daughter of a farmer, it might have been contended that she had been infected in this way. But we are now assured that the cow is at least one of the chief sources of the spread of this disease by means of its milk. In his Harben lectures on "Consumption," the late Sir Richard Thorne-Thorne laid great stress on this aspect of the question. He stated that while, in the adult, tuberculosis had diminished 50 per cent. in the last quarter of a century, it still claimed a very large number of victims amongst children in the form of tabes mesenterica, and he attributed this prevalence to the fact that children are fed so much on milk. Now, if we look at the facts of the case, we find that tabes mesenterica occurs chiefly, if not wholly, amongst the children of the poor and indigent, and that it is extremely rare amongst the children of the well-to-do. The latter have an abundant supply of milk, and other nutritious food, while the former chiefly drink tea, and scarcely know the colour, much less the taste, of milk in their homes. Lest it should be thought that I am drawing upon my imagination, I quote from a paper read by Mr. R. Henry Rew before the Royal Statistical Society, on April 26th, 1892. After quoting from Morton, in his book, "The Diary of the Farm," 1885, that the consumption of milk "has very greatly increased of late years," Mr. Rew says: "I have been able to obtain some figures showing the average daily delivery of milk per family by retailers in a few fairly typical localities. From these I have calculated the consumption per head on the basis of five persons per family." He then gives the following table:—

Mr. George Granville Bantock, M.D. F.R.C.S.ED.

6 Nov. 1907.

STATISTICS OF MILK CONSUMPTION taken from the Books of Milk Retailers in various Districts.

No.	Description of District.	Approximate Number of Families Served.	Average Consumption per day, per Family.	Average Consumption per head.	
				Per Day.	Per Annum.
			Pints.	Pints.	Gallons.
1.	West-End of London	4,000	3·750	0·750	34·218
2.	North of London	2,000	3·250	0·650	29·656
3.	Manchester		2·666	0·533	24·318
4.	„ (Middle-class District)	146	1·500	0·300	13·687
5.	„ (Working-class District)	200	1·000	0·200	9·125
6.	Small Country Town	90	1·624	0.325	14·823
7.	Putney and Wandsworth	700	2·286	0·457	20·838
8.	Small Town (Health Resort)	500	2·000	0·600	27·375
9.	East End of London (one gallon of Milk divided into 37 portions		0·432	0·086	3·923

Mr. George Granville Bantock, M.D., F.R.C.S.ED.

6 Nov. 1907.

I should just like to point out that amongst the well-to-do, the average consumption per head per day is in the West End of London 0.750 pints, or 34.218 gallons a year, whereas in the East End of London the average consumption per annum is 3.923 gallons.

14548. When it says that in the West End of London 4,000 families were served, does that, and do the following figures relating to the West End of London mean that those are the figures given by a particular trader in the West End of London?—I go on to explain that in the following paragraph. "With reference to No. 9 (the East End of London) it is necessary to explain that the figures are based on the fact that a gallon of milk is divided on an average into thirty-seven portions, each portion being, I believe, fetched by the consumer. I have assumed that each family consumes one of these portions every morning and evening. It will be seen that even on this assumption the consumption per head is infinitesimal, and it reveals, incidentally, a significant fact in connection with the dietary of the poor. I may, perhaps, add that the gentleman who was good enough to procure me that particular return is one of the highest authorities on the London milk trade."

14549. That did not seem to me quite to explain it. Does he put together 4,000 families supplied by a number of West End dairymen?—Yes, of course, the returns have been obtained from different milk dealers of families supplied by a number of dairymen, not by one dairyman.

14550. They are such round figures—north of London, 2,000; working-class district, 200; small town, 500—that they do not seem to be actual figures. However, you do not know about it?—I do not. This is a quotation from Mr. Henry Rew's book; he has given this table. Again tabes mesenterica is essentially a disease of mal-nutrition, and is often cured by nutritious diet, of which milk should form an essential part with cod-liver oil and some preparation of iron. And why does this form of the disease attack the digestive tract of children rather than the pulmonary? Because, says the lecturer (Sir Richard Thorne-Thorne), the tubercle bacillus gains entrance through the stomach. I venture to affirm that not a single case has ever been put on record in which the disease has been thus communicated. In this connection I may quote Dr. F. M. Sandwith, who has said that in Egypt women suckled their children for even two years, and all other milk was boiled, and among the cattle tubercle was rare, yet tuberculosis was common. His experience, moreover, had been that tubercular injections gave bad results in surgical tuberculosis. With regard to the tubercle bacillus of Koch, Professor Spina opposed the theory on the ground that if this bacillus were the true cause of tuberculosis the bacillus ought to precede the formation of tubercular nodules. Spina, Charrin, and Kuskow failed to find this bacillus in acute miliary tuberculosis, the last-named affirming that acute miliary tuberculosis does not at all proceed from the bacili of Koch's, and that such bacili only appear there second-hand, proceeding from pre-existing tubercular nodules. Professor Middendorp is of the same opinion, and in a letter to Dr. Vicentini says "the bacilli only accompany pulmonary phthisis in caverns communicating with the bronchi. . . . These microbes, therefore, cannot be called tubercular bacilli, as they are not found in tubercles as such, and have no etimological relation whatever with tuberculosis. For this reason I maintain that tubercular bacilli, in the sense of Professor Robert Koch, do not exist at all." With regard to plague, Mr. Hankin, Chemical Examiner and Bacteriologist for the North-West Provinces and Oudh, reported to the Plague Commission in January, 1899, that there was no doubt that cases of plague occurred among human beings in which no microbes were visible at the time of death. Ridicule seems to be the appropriate weapon to use against the theory that plague is conveyed to the human subject by rats through the agency of fleas! There was a time when the bacillus coli communis was regarded as a most virulent microbe, and by many it is still regarded as such, and yet it is now recognised by the best authorities as a normal inhabitant of the digestive tract, and necessary for the maintenance of health. In the case of typhoid fever, I have shown in the paper already referred to that in not a single instance in which the outbreak has been attributed to water has the bacillus typhosus been found in the incriminated water. I claim, then, to have shown that the poisons of variola, vaccinia, and several other acute infectious diseases, are not and cannot be the product of a bacillus; that Loeffler's bacillus is not a constant, and therefore cannot be the essential, element in the production of an attack of diphtheria; that the essential element in the case of typhoid fever is not the bacillus typhosus; that this bacillus cannot live but for a few hours in ordinary sewage; that not a single specimen of this bacillus has ever been discovered in sewer air, and hence that typhoid fever cannot be attributed to it because of its contained germs; that in the cases of the epidemics at Maidstone and King's Lynn there exists no proof of contamination of the water by typhoidal matter, as indicated by the presence of the bacillus typhosus; that there is no evidence worthy of the name that tuberculosis is due to the ravages of the tubercle bacillus; that the comma bacillus cannot be regarded as the essential element in the production of an attack of cholera, and that the same can be said of plague and its special bacillus; that the so-called pathogenic micro-organisms are constantly found under conditions consistent with perfect health, and that in more than one notable instance they not only appear to, but actually do, exert a beneficial influence. To all, then, who hold by the germ theory I would say, in the words of Oliver Cromwell, "I beseech you . . . . think it possible you may be mistaken."

14551. (*Sir William Church.*) Referring to the first page of your *précis*, eight lines from the bottom, am I to understand that only germs floating in the air were supposed to be dangerous when Lord Lister founded his system of antiseptic surgery, and that those which had settled upon other bodies were not dangerous?—That is not included. The Listerian system was founded on the theory that germs floating in the atmosphere fell into the wounds, and to counteract their influence the spray was used.

14552. But only those floating in the atmosphere?—Quite so. That was the basis of the Listerian method.

14553. What is your ground for stating that?—Professor Lister's statement.

14554. It is not Lord Lister's own statement?—Undoubtedly.

14555. Can you tell me where he states that germs only that are in the air are dangerous, and not those which have settled?—I think if you will just look over what Lord Lister himself said at Berlin you will find that that was the basis of the theory—the germs floating in the atmosphere.

14556. But are you not aware that Lord Lister, at the very time that he was investigating this question, was most particular with regard to the cleanliness of the skin both of the patient and of himself, and also of all the instruments that he used?—Sir Joseph Lister, as he was at that time, actually stated that he did not even aim at surgical cleanliness. He stated that at King's College Hospital after he arrived in London. And you see here what he says: "As regards the spray I feel ashamed that I should ever have recommended it for the purpose of destroying microbes in the air."

14557. Quite so, but that was an additional precaution, was it not?—That was the essence of the treatment, and he used the carbolic acid as a germicide.

14558. Before ever he used the spray what was his object in using germicides? Carbolic acid was what he used. What was his object in washing the skin, washing his own hands, washing the surfaces of the wounds, and keeping them dressed with carbolic acid?—I am not aware that he did it before he introduced the spray. In fact, I think that the use of carbolic acid and the use of the spray were simultaneous, and I believe the idea was founded upon the supposed effect of carbolic acid upon sewage matter—that the carbolic acid destroyed the microbes in sewage; whereas we now know that it does nothing of the kind. I believe that gave Lord Lister the idea of using carbolic acid for the purpose of destroying microbes in the air. Lord Lister seems to have had no idea of destroying microbes in the skin, which were already in the skin, and of which perhaps he was not aware at that time.

14559. But he states himself the necessity of cleansing the skin of the patient and his own hands and the instruments that he uses?—With carbolic acid.

14560. Yes?—Which he believed was a germicide, but now we know is not a germicide.

14561. Do you mean to tell the Commission that if you use carbolic acid in sufficient quantities it does not destroy the bulk of known germs?—Certainly

it does, along with the tissues of the body to which it is applied. You cannot destroy the germ without destroying the tissues of the body, that is to say, that the germs will live in a solution of carbolic acid which will be destructive of tissues.

14562. Quite apart from the body, if you please, do you mean to say that it will not destroy germs in a solution in water or, in what you just now said, in sewage, if you used sufficient?—It will not kill them all; it may destroy a certain number, but carbolic acid to destroy germs must be used in such strength that it will destroy living tissue.

14563. That is not the point I am on at the present moment. You stated that it would not destroy germs in sewage?—That it would not destroy them all; that is to say it did not deprive the sewage of its septic matters; you could not apply it in sufficient quantity, and the practice, as you know, has been given up. The treatment of sewage by carbolic acid has been proved to be an absolute failure, and the very opposite method now is adopted of cultivating the microbes to eat up the sewage matter, not to kill it, but to eat it up.

14564. (*Chairman.*) You say in the second page of your statement that it was in 1891 that Lord Lister acknowledged his error?—Quite so.

14565. What is the date you fix for the introduction of the antiseptic treatment first by Lord Lister?—I really forget the date, but it was many years ago.

14566. You speak of his introducing the spray and the use of carbolic acid at the same time?—That was when he was at Glasgow.

14567. Is that what you call the beginning of the system?—That was the beginning.

14568. When was that?—I could not give you the exact date, but it must have been in the early sixties, if not in the fifties.

14569. As far back as 1860, at any rate?—Yes, undoubtedly.

14570. (*Dr. Wilson.*) You say about 35 years in your *précis*?—Yes; it would be quite easy to find the exact date when he introduced it at Glasgow.

14571. (*Sir William Church.*) Upon page 2 of your *précis* you say that you gradually began to reduce the strength of the solution until at last you used only ordinary London water to wash out or irrigate wounds, and you also, I think, mentioned Mr. Lawson Tait as doing the same thing?—Lord Lister refers to Mr. Lawson Tait.

14572. Did you use the water straight out of the tap?—Straight out of the tap.

14573. Without boiling it?—Without boiling it.

14574. Then you differ from Mr. Lawson Tait?—I do not think so. I think Mr. Lawson Tait did not always boil his water. I do not think he took any trouble in that respect.

14575. Do you think that boiling water sterilises it or not?—Sterilises of what?

14576. Sterilise the water—kills the germs in it?—You have to prove first that there are germs in the water before you can sterilise it or kill them.

14577. You know that Mr. Lawson Tait, although he did not mention it in his paper, did boil the water?—I do not think he did; he did not boil all the water, anyhow.

14578. And you never did?—Never. I had to use hot water, and if the water was too hot I added some cold water to it. I should like to explain my reason for my giving up the carbolic acid treatment. I lost a patient through acute inflammation of the kidneys as the result of carbolic acid poisoning; it was a case of ovariotomy.

14579. I think it is admitted that carbolic acid poisoning was frequent?—I was going to explain how I arrived at my views. A fortnight later I had another case in which the temperature went up to 106 within a few hours after the operation. I had to put the patient in a pack, and got the temperature down, and then I recognised that the symptoms were due to carbolic acid absorption, and I made up my mind to reduce the strength of the carbolic acid. I went from 1 in 50 to 1 in 60. I still got evidence of the absorption of carbolic acid by chemical test. Then I reduced it to 1 in 80; the evidence got less and less. Then I reduced it to 1 in 100, and then, as Lord Lister told us, that a strength of 1 in 40 was the weakest solution that was of any service, I thought when I had arrived at 1 in 100 that the experiment was at an end. And from that time my results began to improve. I do not know whether I am correct, but I think I am correct in saying that there is no surgeon in this country who has performed so many successive successful ovariotomies as myself in a public hospital, for at the Samaritan Hospital I have a record of 90 successive successful ovariotomies without the use of any antiseptic whatever. I think I was justified in every respect in leaving off the antiseptic treatment.

Mr. George Granville Bantock, M.D., F.R.C.S.ED

6 Nov. 1907.

14580. You seem to place in contradistinction to each other the antiseptic treatment and the aseptic treatment?—Yes.

14581. But are they not one and the same?—Not at all. Antiseptic means the use of a substance with a view of preventing septic mischief, or destroying microbes. It is quite correct to say that you have done an antiseptic operation, but it is absolute nonsense to say that you have done an aseptic operation, because you do not know what the result may be. The patient may die of septic mischief within 48 hours.

14582. But surely is not the distinction between the two, if there is any (I do not admit that there is), that the antiseptic treatment was attempting to destroy germs which had got access to the body, and the aseptic is preventing their access?—Attempting to prevent the action of the germs was the idea of the antiseptic method.

14583. What do you understand by surgical cleanliness?—The use of nothing, and the absolute exclusion of dirt of any kind.

14584. But who showed us wherein dirt was harmful? How was that knowledge arrived at?—Dirt may contain specific poisonous matter apart from germs altogether.

14585. And may not specific poisonous matter be in the air, too, and so get on to the dirt?—I do not think it is possible that that specific poison can be in a dry air.

14586. How do you think that what you call dirt, I do not know quite what that is, becomes poisonous and dangerous?—Dirt may contain, as I have just said, some poisonous matter, whatever it may be. We do not know, and we have no means of knowing, what that poisonous matter may be. Even, you may say, you may find dirt free from microbes, and yet it will poison a patient, poison the wound.

14587. What is your authority for saying that?—My own observation.

14588. How do you know that the dirt had not germs in it?—I say it may have.

14589. I understand you to say that dirt quite free from germs is poisonous?—No, I say it may be free. You may not be able to find any germs in a particular portion of dirt, and yet that dirt will be poisonous to the wound.

14590. Would you give me your authority for that?—I have no authority beyond my own experience and observation. I do not think that any observations have been made on the subject.

14591. And are no organisms of any kind obtainable from that dirt?—You seem to misunderstand me. I have not said that dirt has been found free from germs, but I say that it may be free from germs and yet be poisonous.

14592. How do you explain what used to be so common in hospitals—hospital gangrene?—Shall I relate to you an experience of many years ago? When I first came to London, before I began practice, I went into one of the general hospitals of London, where I saw a very distinguished surgeon go up to a case on which an operation had been performed for hernia. He put his little finger into the wound, a suppurating wound, and he took a towel and just wiped it like that (*describing*). He went on to see other patients, and coming to one other patient of the same kind he ran his finger into the wound and did the same thing again. That is what I call dirty surgery; there was no attempt at cleanliness there.

14593. What do you think is the dangerous element in it?—Transferring the fluid from a suppurating wound to another wound.

Mr. George Granville Bantock, M.D., F.R.C.S.ED.

6 Nov. 1907.

14594. So you did not believe in the possibility of contamination of wounds or the carrying of infection through means of the atmosphere?—Certainly not.

14595. Lord Selby wishes to know what would be the difference between a surgeon who acted antiseptically and a surgeon who acted aseptically. Did not Lord Lister himself introduce the term aseptic?—I do not think so.

14596. I think he did?—I think Lord Lister had ceased to operate by the time that that term was introduced.

14597. I think he introduced it himself, and he was very pleased to find afterwards that it was a word used by Hippocrates?—I was not aware of that, but I think it is immaterial even if it be so.

14598. (*Chairman.*) What I wanted you to do, if you could, was to describe to me and to others who do not understand these matters professionally, what a surgeon would do if he were performing a particular operation antiseptically, and how otherwise would he act if he were performing it aseptically?—In performing an antiseptic operation the surgeon would first of all wash his hands in some so-called antiseptic or germicide such as corrosive sublimate, carbolic acid, spirits of wine, or other things. A very elaborate process was invented by Dr. Howard Kelly, of Baltimore. He first of all washed his hands in a strong solution of permanganate of potash.

14599. I do not want every precise detail, of course, from you?—It was a process for the purpose of destroying bacilli or bacteria in the skin. And it has been found that that is an impossibility, because many of these microbes are too deeply seated——

14600. Instead of arguing upon each thing he does, will you just tell us what in fact he does?—Then he would have his instruments in a solution of corrosive sublimate or carbolic acid. He would then wash the skin, probably with germicide. In an operation upon the abdomen in which he would use a sponge, or any operation in which he would use a sponge, the sponge would be soaked or washed in a solution of carbolic acid or some other germicide. The aseptic surgeon uses no germicide to the patient except it may be to the skin. He does not allow the antiseptic to touch a wound or raw surface.

14601. Does he wash his hands?—Yes, he washes his hands.

14602. In the same sort of solution?—Yes, but he does not allow any germicide to touch the wound.

14603. (*Mr. Ram.*) Does he sterilise the instruments?—He may either sterilise the instruments or keep them in a solution of corrosive sublimate, or carbolic acid, or such like.

14604. (*Sir Mackenzie Chalmers.*) What does he do that for?—His idea is to destroy the germs.

14605. Is it effective in sterilising the instruments in the hands?—It is not effective in sterilising the hands or sterilising the skin.

14606. (*Chairman.*) I did not want to go into the question whether it was right or wrong, but I wanted to get first what actually was done. I do not gather from what you have told us so far that there is any difference between the two methods except that in aseptic treatment certain things are not applied to the skin of the patient?—And the tissues of the patient, that is the most important thing.

14607. Is that the difference?—Practically.

14608. (*Sir William Church.*) Did you in your practice make use of sterilised dressings?—No, I used the dressings that I got from the surgical instrument makers or the man who supplies these things. The gauze I used directly as I got it from the surgical instrument maker.

14609. You did not take any precautions to sterilise your wool, or your gauze, or your bandages?—None whatever. And I am not afraid of exposing a wound to the open air. I have operated on the breast and applied no dressing whatever. Any case where I could not draw the edges of the skin together I have kept exposed to the open air, and it has healed up perfectly.

14610. All surgeons used to do that at one time. They had to leave the wound exposed if they could not get a skin covering?—They did not leave it exposed; they put some dressing upon it, some ointment or something of that kind. But I purposely in a public hospital did that as an experiment, and everybody knows that the best method of treating a raw surface, if you graze your skin, for instance, is to let the blood dry upon it—do not apply any dressing to it, and it heals up forthwith.

14611. The answer that you gave me was what I wanted; that you in your own practice made no use of sterilised dressings at all?—Absolutely none.

14612. You used absorbent wool, or anything of that sort, as it came from the maker?—Yes, quite so, absolutely. That I have done now for the last 30 years, I should think.

14613. On page 4 of your *précis*, towards the bottom of the page, you say: "Thus in the modern septic tank, which is now so largely used in the treatment of sewage, it is the action of the micro-organisms, whether aerobic or anaerobic, which dissolves the sewage, and it is the continuous action of these microbes which converts all manurial matter into the saline constituents which are essential for the nutrition of plant life." Do you mean that plants do not suffer from parasitic organisms?—Undoubtedly they do. At least my observation in a greenhouse is of this nature, that it is only the unhealthy plants on which you find the aphides.

14614. By parasites I did not mean aphides, I meant micro-organisms?—I do not know that they suffer from micro-organisms. They suffer from visible organisms such as I mention, but I do not know that they suffer in any other way.

14615. Not from microscopical fungi?—Yes, from fungi; but fungi are not microbes, I believe.

14616. Am I mistaken or not in thinking that if you filter the fluid of small-pox vesicles it does not convey the disease?—I am not aware of any experiments of that kind. I know, as everybody knows, that if you take an infinitesimal quantity of the contents of a vesicle and put it under the skin you get an attack of small-pox.

14617. But you were not aware—I think I am correct—that filtered vaccine fluid does not convey the disease?—I am not aware of any observations in that direction.

14618. If that is correct it looks as if the disease was dependent upon some particular matter?—But you know that you do not prove anything. You do not prove the exact cause.

14619. Something must be left behind in the filter?—You prove that there is something, but you do not know what that something is. And it certainly is not a microbe.

14620. You say so?—No one has found the microbe yet, anyhow.

14621. I admit that it has not been found?—And you have no right to assume that it is the result of the action of a microbe.

14622. You also say on page 6 "it is now generally admitted that the tubercle bacillus is not found in the sputum in the early stage of phthisis, but only when necrosis of the lung tissue sets in." What is your ground for saying "it is now generally admitted." What are your authorities for that?—I have referred to several authorities, and I think that is the result of the reference to those authorities, that no one has yet discocered the tubercle bacillus in the early stage of the miliary tuberculosis.

14623. Is that so?—That is so, I believe. If you can refer me to any author or any experimenter who has discovered it I should be very pleased to know who he is, but, so far as my reading goes, the result is that no one has yet discovered the tubercle bacillus in the early stage of miliary tuberculosis.

14624. You mean before tubercles are found?—In the early stage of miliary tuberculosis.

14625. I wish to know what that is?—Miliary tuberculosis can be found in a very early stage. I do not know what the microscopical appearances might be; you know more about that than I do, but I take the word of the eminent men to whom I refer.

14626. That is just what I am asking. Who are your authorities that you quoted?—I have quoted some here. I do not know whether I am correct in using the word "generally," but I mean that it is extensively admitted.

14627. I will put my question in another way. Do you mean by the early stage of miliary tuberculosis a

stage before you can see tubercles with the naked eye?—I do not know whether the term "early stages of tuberculosis" is confined to that stage in which it is not possible to see them by the naked eye, but they can be seen by the microscope.

14628. I wished to know what you meant by the early stages. But you do not maintain that when tubercles sufficiently large to be seen by the naked eye are found you do not find the bacillus in them?—I do not know whether the bacillus is found; I cannot say anything about that; but in a still earlier stage the bacillus is not to be found. When the tubercle is large enough to be seen with the naked eye it must be considerably advanced.

14629. I wanted to know what you meant by the early stages?—Yes, that is what I meant.

14630. You say that they are not early stages when the tubercles are visible to the naked eye?—I should say not by any means.

14631. Might I ask who Dr. Vicentini is?—Dr. Vicentini is an Italian doctor, living at Chieti, in Italy. He is a very good English scholar, and he reads and writes English perfectly, and when my paper on the "Modern Doctrine of Bacteriology," or the germ theory of disease, was first published, he sent his pamphlet to me. He had seen mine and read it, and was struck by the similarity of the views which he and I held, and sent me a copy of his pamphlet. I am sorry that I have not been able to bring it down with me, because in changing houses unfortunately I have mislaid it, but these quotations in inverted commas from Vicentini are from that pamphlet.

14632. Is he a skilled bacteriologist?—Evidently, yes.

14633. What has he published, could you tell me?—Unfortunately I did not put down the name of the pamphlet; but he has written a work on whooping cough and the micro-organisms associated with it.

14634. And when did he publish it, if you could tell me?—My paper was read in 1899, and Dr. Vicentini sent me his paper the same year; my pamphlet was published in the early part of the year.

14635. His work was published before 1899?—It must have been, as he sent me the printed pamphlet.

14636. I do not quite follow what you say at the bottom of page 7 of your *précis*. Why is it incomprehensible and incredible that smallpox can spread through the action of a special form of bacillus? Why should it not spread through a bacillus just as much as through a poison?—There is no condition that I know of in which such a state of things has been found or has been suggested even.

14637. But we do not know very much about it, and it seems to me no more incomprehensible or incredible that its spread should be due to bacillus than that it should be due to the poison?—To my mind it is utterly incomprehensible. I am giving my own opinion.

14638. You have given the reason, that it is something that is incomprehensible to your mind?—Yes, we do not know what the action of smallpox poison is in the human subject or the animal subject.

14639. Turning to page 9 of your *précis*, you say that this bacillus of Loeffler's is frequently present in some exanthemata, and also in healthy persons. Are you referring to Dr. Hewlett's paper on that?—Not alone, but the literature upon the subject is so full of that idea that I did not think it necessary to refer to any particular writer.

14640. Then what is your authority for saying that in cases of tonsillotomy the Loeffler bacillus is present?—I did not say that it is present, but that it has been found in cases of tonsillotomy.

14641. You say "A still more striking example is afforded in cases of tonsillotomy, wherein, upon the incised surface, a greyish membrane is formed, in which the bacilli abound without constitutional disturbance or any sign of diphtheria"?—I think you will find that I gave my authority for that.

14642. A greyish membrane is an exceedingly common thing after an operation for tonsillotomy; but apparently we do not get diphtheria with it. What is your authority for saying that "Loeffler's bacilli abound without constitutional disturbance or any sign of diphtheria"? You may have diphtheria after tonsillotomy too?—You may have; but I think I gave my authority for that statement. You see that is a quotation, "A still more striking example."

Mr. George Granville Buntock. M.D. F.R.C.S.ED.

6 Nov. 1907.

14643. I want to know what your authority is and where you are quoting from?—I think Scharoz is the authority for that, but it is a quotation, as you see. You will find his name at the top of page 10. That is my authority for quoting it from the "Deutsche Medicalische Woche."

14644. Have you any evidence of fluids from these throats producing diphtheria without the presence of the bacillus?—No. I have no evidence; but there is the evidence that in a great many cases of true clinical diphtheria the bacillus is not to be found, and then again in a perfectly healthy throat the bacillus is to be found without any of the symptoms.

14645. But here you state "if you allow some of the discharge from the throat of a subject of this disease to gain access to that of a presumably healthy individual you may" produce the disease?—Yes, you may, but not necessarily.

14646. Have you any evidence of the disease being produced in that way?—I think you will find the answer to that in the following sentence, if you read it:—"You may point to a number of cases in which medical men in the fulfilment of what they conceived to be their duty have sacrificed their lives in the heroic attempt to succour their patients."

14647. Then they got the bacillus too?—There is no evidence that there was a bacillus. We know that in many cases of clinical diphtheria the bacillus is not to be found. You have no right to assume that in those cases where death has resulted from getting some fluid into the throat in the operation of tracheotomy the bacillus was present.

14648. But you have no right to assume that it was absent?—No. Then we are on an equal footing. You have no right to be top sawyer over me in that case.

14649. I thought you illustrated this as showing that it was the fluid that was the dangerous part?—I say that it is the fluid which is the dangerous part because the fluid is always there, but the bacillus is not always there.

14650. That leads me to ask another question. You say that there have been numerous cases of what you call "clinical diphtheria" in which the bacillus has not been found. What do you mean by "clinical diphtheria"?—Where you have all the symptoms characteristic of diphtheria.

14651. And followed by the after-results of diphtheria?—It does not matter what the ultimate termination of the case may be. What you have to determine is, is this a true case of diphtheria clinically or not? The patient may die or may recover. We do not require to refer to the after-results.

14652. Then you merely mean to state that it is (what everybody will allow) a very difficult question to decide whether the patient is suffering from diphtheria or not?—I imagine that there is some considerable difficulty, and I believe that many cases of sore throat are returned as cases of diphtheria at the present day.

14653. But to finish the clinical picture, can you bring before us any cases of what you say clinically were diphtheria which were followed by the ordinary sequels of diphtheria, that is to say paralysis, etc.?—I am not prepared to bring forward any cases on my own account, but I refer to the general literature on the subject, which is quite sufficient for me.

14654. Then what you mean by "clinically diphtheria" is a case in which there may be a difficulty in forming an opinion from the appearance of the throat and symptoms of the patient, whether it is diphtheria or not?—No, that does not represent my views, I mean by a case which is clinically diphtheria, that it must present the characteristic symptoms of the disease, whatever you may consider the characteristic symptoms.

14655. Then if I choose to consider the presence of the bacillus as a characteristic of the disease, I am right in excluding those cases which have not that from the category of diphtheria?—But that does not correspond with practice; that is not practical. It may be your view, but it does not correspond with the observation of the profession generally.

14656. You have given me no reason for proving that clinically these cases are diphtheria. You cannot tell

Mr. George Granville Bantock, M.D., F.R.C.S.ED.

6 Nov. 1907.

me whether these cases furnish in about equal numbers of the ordinary sequels of diphtheria as those in which the bacillus is present?—I do not think I am called upon to express myself definitely on that point. You cannot exclude a case of diphtheria because the patient does not get paralysis after it.

14657. I only wished to know whether you can give me any instance of these cases in which the symptoms occurred without the bacillus being present?—I cannot from my own practice, but from the literature of the subject.

14658. You state here distinctly that by the inoculation of bacilli: "You also convey the fluid in which they are bathed, in which I contend they live, and which, in my opinion, constitutes the real essence of the disease"?—Yes, that is the poison.

14659. Still you cannot bring any evidence before us that these cases which have contracted the disease from the fluid alone without the bacillus have any of the ordinary sequels of diphtheria?—Not from my own observation. I take it from the literature of the subject.

14660. Then might I ask you who the "many observers of eminence and authority in this field" are to whom you refer on the same page, who "concur in denying the connection of the Loeffler bacillus with diphtheria as cause and effect." Could you tell me some of them?—There again I am dependent upon the common literature of the profession on the subject. I have not put down all the names.

14661. You cannot give me the name of any man of eminence?—I cannot. But that is the result of my reading. It is impossible always to remember the names of the authors you read.

14662. I should like also to know what proof you have that if you reverse the proposition you are correct?—It is a matter of reasoning simply. It is not a question of proof. I say it appears to me to be the more sound reasoning. It is not a matter of proof at all; it is a matter of opinion.

14663. Passing on to the bottom of page 11, you say "Coming now to tuberculosis I will not dwell on Koch's 'tuberculin fiasco,' which was hailed by the profession as a panacea for tuberculosis." Was it not rather hailed by the public than by the profession?—No, the profession also.

14664. Was not Koch himself averse to it, and did he not have his hand forced to a great extent?—Not by the public alone, but by the profession. I remember perfectly well that there were some American gentlemen over here watching my practice at the Samaritan Hospital, and they expressed a very strong desire to go over to Berlin to get some of this tuberculin.

14665. You admit that he himself was not desirous of tuberculin being brought out then as a cure?—I believe it is correct to say that.

14666. His hand was forced, as you say, by the profession; I thought rather by the public?—It was not by the public. I think the profession had as much to do with it as the public.

14667. That is a matter of no importance; but you admit that Koch himself did not wish it—it was against his wishes?—I have heard so. I believe I have read so.

14668. Do not you think that light has been thrown upon the action, or I might even say the dangers, of tuberculin treatment, by what we know now as opsonins?—I do not know anything about that subject; that has recently come up, and I have not paid any attention to it.

14669. You have not followed Sir Almroth Wright's work?—No, not with any degree of attention.

14670. What is your authority for stating that the bacillus of tuberculosis is favoured in its growth by air, light and sunshine?—I think it is a fact that those conditions are favourable to its growth instead of to its destruction; that is to say, so long as it has nutritive material to live upon.

14671. Surely that is not generally held, is it?—I am afraid that I hold several views which are not generally held.

14672. That is your own view?—That is my own view, certainly.

14673. You are not aware of anything contradicting it?—No, nothing.

14674. You are not aware that many experiments have been made as to the effect of light, especially sunlight, on the tubercle bacillus?—When isolated from the conditions in which they live it is very likely, but I am not aware of any experiments which have been made upon the tubercle bacilli in the natural conditions under which they live.

14675. Of course, directly you have them under investigation they are not in their natural condition?—That is just it. No allowance is made for that.

14676. I admit that they are not in their natural condition; but still are you not aware that experiments done with them in captivity, if I may use the term, do not support that view?—But I do not see how they can support any other view.

14677. Simply that the more light, especially sunlight and air, that you expose them to, the more rapidly they die?—As soon as you isolate them from the natural conditions under which they live, then, of course, they are likely to die very soon.

14678. One other question with regard to this very remarkable case of your own that you bring before us. On the same page you say: "That this was an example of tubercular disease I have no doubt whatever if we are to put our trust in macroscopical appearances and the attendant symptoms." Then, as a matter of fact, the tubercle bacilli were not seen under the microscope in that case?—No.

14679. Therefore you have no evidence that they are present there?—No, certainly not, but that the disease was tuberculosis I have not the slightest doubt, and no one has a right to question my opinion upon that point.

14680. Pardon me, I think everyone has the right?—From the macroscopical appearances I think one can perfectly safely say that a case is tubercle or not tubercle. I think you would bind us too closely if you denied us that privilege.

14681. But I think you admitted that this organism called the tubercle bacillus was at all events associated with a certain disease?—Not necessarily. In many cases of phthisis, in the last stage of the disease, you do not find the bacillus in the sputum; that is a fact.

14682. But you find it in the body, do you not?—I do not know. I did not go so far as that.

14683. On page 15, about the middle of the page, in the second paragraph, you say: "I venture to affirm that not a single case," that is of tuberculosis, "has ever been put on record in which the disease has been thus communicated"?—Yes, I affirm that most confidently.

14684. You mean by that, I suppose, only in man?—I am speaking of the human subject, of course.

14685. But do you mean to say that no case has been put on record in which the disease has not been thus communicated to animals?—I have not said anything of that kind. If you will look at my *précis*, I am speaking of children. I am speaking on the subject of tabes mesenterica.

14686. You say "I venture to affirm that not a single case has ever been put on record in which the disease has been thus communicated"?—By means of milk.

14687. That is to man, I understand?—Quite so. I am not dealing with animals.

14688. Do you hold the same with regard to animals?—I have nothing to do with animals.

14689. Would it modify your opinion at all if you learnt that, for instance, monkeys which have received only a single feeding or so with tubercle bacillus have contracted tuberculosis?—I have nothing to do with that question. I have asked over and over again for the details of a single case in which tubercle or tuberculosis has been conveyed to a child or a human subject by means of milk. I get no answer.

14690. And you put out of account all experiments on animals?—Yes, absolutely.

14691. May I ask who Professor Spina is? I am afraid I do not know his name?—He is an eminent Continental observer. Judging from the name, I should say he was an Italian.

14692. Would you tell me what he has written and where he has published his works?—I think you will find that that is a quotation from Dr. Vicentini.

14693. I wish to be allowed to consult his works, to be referred to his works?—I must try and find that pamphlet of Vicentini's in which you will probably get the reference.

14694. Perhaps you will kindly send the Commission the information?—If I can find it I shall be very happy to do so.

14695. And Kuskow. Charrin's name I do know, but who is Kuskow; perhaps you will kindly send that name to us and reference to his works?—If I can find it I shall be very happy to do so. The work from which I have quoted by Dr. Vicentini is "Bacteria of the Sputum."

14696. And also if I might ask for Dr. Middendorp's work?—That also, I believe, I got from Vicentini.

14697. (*Dr. Gaskell.*) Of what nationality is Professor Middendorp?—German or Dutch. I think he is German.

14698. (*Sir William Church.*) I should like also to ask you why you say on page 16: "Ridicule seems to be the appropriate weapon to use against the theory that plague is conveyed to the human subject by rats through the agency of fleas"?—Yes, I think so.

14699. Why is ridicule the only appropriate weapon? Surely it is not?—I believe that one gentleman has given evidence here already on this question, and he said that one of the precautions which they took in avoiding the bite of the fleas was that they wore top-boots.

14700. (*Chairman.*) Who wore top-boots?—The experimenters, I think. I think if anything could be ridiculous that is ridiculous.

14701. (*Sir William Church.*) I do not remember it. I may not have been present. But why is ridicule the appropriate weapon to use against the theory that malaria is conveyed by mosquitoes?—No, not so much against the theory that malaria is conveyed by mosquitoes. But I contend that that does not explain the origin of the disease.

14702. We have no knowledge of the orgin of anything, have we?—I do not know, but the current idea is that malaria is produced and propagated by the agency of mosquitoes.

14703. Not produced—propagated by mosquitoes?—I will give you a case in point. In the Nile Valley there is a district of about 300 miles in length in which there are no inhabitants, yet it is pronounced to be one of the most deadly districts in the globe in consequence of malaria; but there are no inhabitants by whom the disease can be propagated by mosquitoes from one to another. That shows that we have not arrived at the origin of the disease; and it is well known that when you turn up virgin soil you get malaria as the result.

14704. That is an old belief?—And it is well authenticated.

14705. Quite so. There are explanations why that is the case, are there not: that in the first work of turning up the soil you often cause stagnant water, puddles?—That is not the explanation.

14706. But you do not think that ridicule is the right weapon to use against the belief that malaria is propagated by mosquitoes, do you?—No, I do not say that.

14707. Do you think that there is anything more ridiculous in the possibility of fleas conveying a disease than of the tsetse fly conveying a disease?—That is another thing altogether.

14708. I wish to know why this is ridiculous; why is ridicule the weapon to be used; and whether there is any difference between the possibility of the communication of plague by fleas and the possibility of the communcation of nagana by the tsetse fly?—The tsetse fly is on the same plane as the wasp; it develops its own poison. The wasp does not get its poison from outside, or the bee.

14709. The tsetse fly does not develop its own poison?—I think it does, and the same with the wasp.

14710. Then we will leave the tsetse fly, and I will ask you, do you think that there is such a thing as tick fever?—Very likely. I do not know anything about it.

14711. You think that with the exception of malaria the impossibility of disease being conveyed by infection is ridiculous?—I think in those cases that you refer to the disease is not a disease conveyed by the animal. The effects are the result of the poison secreted by the animal itself. In the case of the tsetse fly, for instance, and in the case of the wasp and the bee, they do not derive the poison from any other source than their own bodies.

Mr. George Granville Bantock, M.D., F.R.C.S.ED.

6 Nov. 1907.

14712. I will put it in another way. You think the explanation that has been suggested for sleeping sickness is incorrect altogether?—I do not know anything about sleeping sickness.

14713. What is your authority for saying that the presence of the bacillus coli is necessary for the maintenance of health?—I took that from the late Professor Kanthack, who read a paper at Liverpool, in which he pointed out that when the bacillus coli was absent from the intestinal track the individual was not in a healthy condition. You will find that in his paper.

14714. When was it published?—It was read at Liverpool before the British Association. I forget the exact date.

14715. Do you mean the British Association or the British Medical Association?—The British Association, because I think it was in the September when Sir Joseph Lister, as he then was, read a paper at Liverpool; it was at the same meeting.

14716. You do not remember the year?—It must have been about 1896 or 1897.

14717. Never mind, I will not trouble with the year. I daresay I shall be able to find Professor Kanthack's paper. But are you quite sure that your statement is right that the typhoid bacillus has never been discovered in water?—I believe so. There may be one solitary instance, but I think it will be a solitary instance which will prove the rule. It was not discovered at Maidstone. It was not discovered at King's Lynn. You know what an outcry there was in the case of Maidstone, and not a single bacillus was found in the water at Maidstone.

14718. I should like to ask you on what grounds you say that in the cases of the epidemics at Maidstone and King's Lynn there exists no proof of contamination of the water by typhoidal matter. Let us take Maidstone?—It was supposed that the disease had been communicated through the occurrence of a case of typhoid fever amongst the hoppers. Now the disease began in July, and the hopping season does not commence until September. The first case occurred at Barming; another case occurred about a fortnight afterwards in the neighbourhood of Barming, and no connection could be shown between those two cases.

14719. Might I not ask you whether there was not only in September, or whatever month you just now mentioned, but also in July, quite a possibility that the spring might be fouled by enteric discharges?—But there was no case of typhoid fever in the neighbourhood, and there had not been.

14720. Well, none was known?—But you cannot affirm anything unless you know it as a fact.

14721. But still you would admit that where you have a source of water supply which is capable of being fouled, it is possible—I do not say that it is the case—that it might have been fouled by a passer-by who did not stay in the neighbourhood?—You have got to prove it.

14722. Quite so; but you admit that the spring was found to be in a condition in which it was possible to be fouled?—No, I do not think it was. I went into that subject very fully in my pamphlet from which my *précis* is taken.

14723. Then on the last page of your *précis* you say that the so-called pathogenic micro-organisms in more than one notable instance not only appear to, but actually do, exert a beneficent influence. What is your authority for that?—A few years ago Dr. George Stoker was treating some cases of chronic ulcer. He had a patient, whom I saw myself, with a large chronic ulcer on each instep. These cases were treated by oxygen gas mixed with air. Mr. Jonathan Hutchinson was asked to see these cases, and he suggested that the one case should be treated with corrosive sublimate solution and the other with oxygen gas. The result of that was that in a short time the one treated with oxygen gas was found to be healing very nicely, whereas that treated with corrosive sublimate solution was making no progress. Then some gentleman went up from some bacteriological institute and took a cultivation from both these wounds. The one treated with

Mr. George Granville Bantock, M.D., F.R.C.S.ED.

6 Nov. 1907.

oxygen gas showed that the wound was swarming with staphylococcus pyogenes; the one treated with corrosive sublimate was sterile. Dr. Stoker found by subsequent observation that the more abundant the staphylococcus pyogenes was the better the case was going on, and if in the course of treatment the case seemed to be getting slack in its progress he would take some of the secretion from the healthy wound and put it upon the one that was not making such progress, on the ground that it was desirable to increase the vitality of the staphylococcus or the streptococcus as the case might be. Then Dr. Stoker brought the case before the "British Medical Association," and he appended to it a microscopical or bacteriological examination. The Editor of the "British Medical Journal" refused to put in the bacteriological examination, and simply said that the bacteriological results were astounding. I say that that is extraordinary evidence in favour of the view that I take.

14724. I do not follow it, but it may be so. It seems to me it is evidence that the staphylococcus or streptococcus, whichever it was, acted as a healthy stimulus to the ulcer?—It is evident, because when there was no staphylococcus there the ulcer was not healing.

14725. And I would suggest that in both cases the rest had a good deal to do with it—the patient not using his legs?—The rest could have nothing to do with it, because they had already been under treatment by rest for a considerable time, so that rest had no part nor parcel in it at all.

14726. (*Dr. Gaskell.*) Who was the bacteriologist?—I do not know. He came up from one of the institutions. I do not know whether it was the Clinical Research Association or not, but he was a skilled bacteriologist and microscopist.

14727. And where is this statement of Dr. Stoker's published?—In the "British Medical Journal." I give it you very fully in this pamphlet of mine (*handing in a pamphlet*). All the facts are given there.

14728. (*Sir William Collins.*) Your work has been chiefly surgical, has it not?—Yes.

14729. Especially in gynecological surgery?—Yes.

14730. Have you ever yourself practised vivisection?—Never. I have never even seen an experiment.

14731. Do you think that you have derived any advantage in your surgical treatment from knowledge acquired by vivisection?—None whatever that I am aware of.

14732. And do I correctly understand you to suggest that in no case has any micro-organism been shown to be the true cause of any specific disease?—I am not aware of any case.

14733. Does that apply equally to such things as malaria and tsetse fly where a cause of animal origin rather than vegetables is suggested?—Quite so.

14734. As well as bacterial disease, so called?—Yes.

14735. I understand you to admit that you find the micrococcus in association with disease?—I believe so. I accept that as correct.

14736. What relationship, if any, do you think subsists between them?—That the micro-organism is the result of the conditions just as you find grouse growing on moors and partridges and pheasants on arable land and salmon in running rivers, and so on.

14737. Do you suggest that any of these bodies, vegetable or animal, which are alleged to be pathogenic in their character, proceed from the body itself, or are they wholly from without?—I think they proceed from the body. For instance, bacteriologists tell us that we are swarming with bacteria.

14738. Do you suggest that they originate *de novo*?—I think it is possible. I do not know. I have never studied that part of the question, but I am quite of the belief that some diseases originate *de novo*. But with regard to bacteria that is another thing.

14739. (*Chairman.*) Do you accept what the bacteriologists say, that we are swarming with bacteria?—I accept it because I have no means of disputing it.

14740. (*Sir William Collins.*) It is not unknown, is it, that fluids which are entirely free from micro-organisms can produce very violent inflammation. Take the case of jequirity, which is obtained from *Abrus Precotorius*. That will produce acute ophthalmia, although it is free from organisms, will it not?—I do not know. I have no experience of that.

14741. Has a great distinction been drawn between the aseptic system of surgery and the antiseptic system?—I draw a very marked distinction between the two, but the current view is that the antiseptic and the aseptic treatment are the same.

14742. Did Lord Lister at one time draw a great distinction between the two?—I am not aware that he did. I do not remember any reference on the part of Lord Lister to the aseptic treatment.

14743. Did Lord Lister include in the antiseptic system such things as frequent change of dressings, free ventilation, dependent openings, and a judicious selection of cases for operation?—I think very likely. Any sensible surgeon would do those things.

14744. Did Lord Lister at one time criticise Sir John Burden Sanderson's work, because Sanderson said that dry air did not contain putrefactive organisms?—I should agree with Burden Sanderson in that. I do not know whether Lord Lister objected to it or had anything to say on the subject.

14745. Was the carbolic spray, in the earlier years of antiseptic surgery, regarded as a most important part of the procedure?—A most important part of the procedure, according to Lord Lister's own showing.

14746. It was finally renounced, as I understand, because, as Lord Lister stated, it was founded upon a theory that was physically impossible?—To affect the microbes.

14747. Did not Lord Lister call attention to the fact that inflammation may occur independently of any atmospheric external influences?—I think so; I believe so.

14748. Did he include in antiseptic surgery such things as the dry dressing of McVail?—Lord Lister included dry dressings impregnated with carbolic acid.

14749. But what was McVail's dry dressing?—Probably like my own, simple.

14750. Was it lint spread with lard?—I should say not. That is not dry dressing. Dr. McVail was in the habit of leaving his amputation cases exposed to the air until the surface got glazed over. That was a peculiarity of his practice.

14751. And some other surgeons at one time did the same?—Yes, but I am speaking of McVail.

14752. Was Mr. Lawson Tait practically on the same lines with yourself?—Almost absolutely.

14753. Was Sir William Savory?—Yes.

14754. Can you mention any other?—Savory, Tait, and myself were the only three who ventured to oppose the antiseptic or Listerian method. It might be interesting to know the result of my reading of a paper at one of the medical societies of London on hyperpyrexia, after Listerian ovariotomy, in which I showed that my best results were with the non-Listerian method. The result of my reading that paper was that I was twice blackballed by that society, so strong was the prejudice at that time existing against my views and the views of Mr. Lawson Tait and Sir William Savory.

14755. I understand, then, that your practice, based upon your views in the matter of ovariotomy has shown an unrivalled success?—Quite so; and it was a case of unsuccess that opened my eyes in the first instance—that is to say, I lost a patient from acute nephritis—carbolic acid poisoning.

14756. That was not a very unusual occurrence at one time?—At one time, I believe, it was not at all unusual. The evidence of absorption of carbolic acid was at one time very conspicuous.

14757. Did Lord Lister say that if the air did not contain putrefactive organisms it would affect his surgical practice in a most important manner?—I do not remember that statement on Lord Lister's behalf.

14758. Does anybody use the carbolic spray now?—I do not think so.

14759. I see that attention has been called in Mr. Paget's book to the alleged relation between the work of Semmelweis and that of Lister. Have you anything to say on that?—I do not think there is any connection between the two. Semmelweis went in for extreme cleanliness after parturition, and I think sanitary arrangements generally, and he would not allow students from a *post-mortem* room to attend upon cases in labour.

14760. Do you claim him as an aseptic or antiseptic authority?—I should call him aseptic, if you use the term at all, but I do not use the term aseptic, because I think it is a ridiculous term.

14761. I see on page 82 of that book of Mr. Paget's a quotation from Haller in 1849, in which he said: "The importance of these observations" (alluding apparently to Semmelweis) "is above all calculation both for the maternity department and for the hospitals in general, but particularly for the surgical wards"?—Yes; that was long before the era of the antiseptic treatment or bacterial observations.

14762. In regard to the question of tubercle, to which you called attention, whatever may have been the pressure upon Koch, is it not the fact that he published a book called "The Cure of Consumption"?—I could not say. I know of nothing but his announcement at Berlin. I do not know of any work that he has written on the subject.

14763. Have you not seen a work entitled "The Cure of Consumption: Further Communications on the Remedy for Tuberculosis by Professor Robert Koch"?—No, I have not seen it.

14764. Are you not aware of the claim there made that "phthisis in the early stages can be cured with certainty by this remedy"?—I believe that claim has been made.

14765. You do not accept it?—I do not.

14766. Do you know of any case of consumption that has ever been cured by tuberculin?—I am not aware of any case that has been cured by tuberculin. I am aware that cases of tuberculosis have been cured. I was taught that in my student days.

14767. As regards diphtheria and the presence or absence of the Klebs-Loeffler bacillus, I see that Dr. Newman, Medical Officer of Health for Finsbury, who has just been appointed Medical Officer to the Board of Education, in his work "Bacteriology and Public Health," says the organism may exist in the healthy throat without producing the recognised clinical symptoms of diphtheria. I understand that you agree with that view?—Yes, quite so; in fact, that is almost universally accepted now.

14768. He also states: "It should be remembered that about 20 per cent. of all cases of diphtheria offer no bacteriological evidence of infection. It therefore comes back to the point of broad judgment and common-sense. The clinical condition is the main fact for guidance, and the bacteriological must not usurp it"?—I agree with that.

14769. Then he says, "Whilst in 72 per cent. of notified definite cases of diphtheria the bacillus may be found, it has been shown that in apparently healthy persons who have not suffered from diphtheria the bacillus diphtheriæ may be present." You agree with that?—Yes, I agree with that.

14770. And that "Hewlett and Murray found 15 per cent. of the children in a general hospital had diphtheria bacilli in their throats"?—Those are statements which I quite accept as *bona-fide* fact.

14771. Do you think that suggests that there is the presence of the alleged cause with the absence of the alleged effect?—Yes.

14772. Or the presence of the alleged effect and the absence of the alleged cause?—It comes to that.

14773. The President of the College of Surgeons when he gave evidence before this Commission alluded to various instances in which surgery, in his opinion, had been assisted by vivisection experiments upon living animals, and amongst them was the treatment of septicæmic infections by sera. Have you anything to say with regard to that?—I have no experience of such treatment.

14774. In regard to the question of Listerism, the President was asked two or three questions by myself, so I will just read them to you and ask your views about his answers. At No. 7845 I asked: "As regards Lister's work, I suppose one would be right in thinking that there have been considerable modifications in the Listerian doctrine between 1876, when, as Mr. Lister, he gave evidence before the Royal Commission, and the present time." The reply was: "I do not quite follow that." I then asked: "For instance, in regard to the use of the spray and drainage, and so forth, there has been a very considerable alteration in technique, if not in the principles upon which Listerism was based?" The reply was: "The technique of the employment of facts which he has laid down, the technique of the employment of the treatment which is based upon the facts which he has discovered." Then again I asked: "Should I be wrong in thinking that Lister laid great stress upon the use of the carbolic spray and drainage?" And the reply was: "Quite so. Those are all modified now. The spray we know is an abolished thing." Have you any further remark that you desire to make in reference to that, arising out of your own experience?—I think Mr. Henry Morris maintained that abdominal surgery was very much indebted to experiments on animals. I entirely deny that. Abdominal surgery is the result of successful ovariotomy, and to that alone is due the success of abdominal surgery generally. It was shown that the peritoneum was not the sensitive membrane which it was always regarded as being. I recollect Sir John Erichsen asking me whether I would treat a knee joint in the same way as I treated the peritoneum, and I said, yes, certainly, I should have no hesitation in treating it just as I should the peritoneum. That was when I was not using the spray or carbolic acid, and experience has shown that I was right.

Mr. George Granville Bantock, M.D., F.R.C.S.ED.
6 Nov. 1907.

14775. Do you recall a case in which Lord Lister, in one of his classical essays, attributed suppuration following an operation on the knee joint to the fact that the spray had been interrupted in its course by the removal of the drainage tube?—I do not remember that particular case, but I remember one case in which the failure of a breast case was attributed to the fact that there was a pinhole in the macintosh covering the gauze dressing.

14776. Then, as regards cancer research, do you think it is idle to look for light from experiments on animals with regard to that?—I am afraid so.

14777. Has any light been obtained at present?—None whatever, so far as I know.

14778. And as regards hydrophobia, I do not think you have mentioned that. Have you anything to say upon that subject?—I should like to say that I know of nothing which is less creditable to the profession than the readiness with which they accepted the claim which has been set up on behalf of the Pasteurian treatment of rabies.

14779. Possibly you would desire to amplify that answer. I do not quite follow at the moment?—I think in the first year there were some 3,000 inoculations. There were only a certain number of deaths, and they claimed that in all the other cases in which death did not occur the cases should be regarded as cures. That is the claim that has been set up by the followers of Pasteur: that every case in which the disease is not manifested after inoculation is a case to be regarded as a cure.

14780. (*Chairman.*) Is that a publication of Pasteur's that you are quoting? Are you quoting any statement of Pasteur's to that effect?—No, not of Pasteur himself.

14781. We have had no evidence of it. We have had evidence about it, but we have had no evidence that such a claim is made?—The claim is made, I said, by the followers of Pasteur.

14782. We have had many witnesses who agree with him as to his method of treatment. I do not think that any of them have made that claim?—We must be guided in this matter very much by statistics.

14783. Statistics are very useful to prove or disprove a claim, but you were saying that the claim was made?—Yes, that claim was made. I could not give you the exact reference to the work in which it was made.

14784. (*Sir Mackenzie Chalmers.*) Who made it?—It is a general claim made by the followers of Pasteur—by the Institute.

14785. (*Chairman.*) A general claim made by the followers of Pasteur is a little vague. At any rate, it was not made by Pasteur. Some people who believe in Pasteur may have made it?—I have not spoken of Pasteur alone. I think much more blame is to be attached to his followers.

14786. (*Sir William Collins.*) I see in 1886 (Question 11659) the cases treated were 2,671, and the deaths 25, or a mortality of 0.94 per cent.?—I should like to read a letter that I have here. I paid considerable attention to this matter in the early period, but of late years I was so disgusted with the whole thing that I have not paid any attention to it. But I wrote quite

Mr. George Granville Bantock, M.D., F.R.C.S.ED.

6 Nov. 1907.

recently to a friend of mine, Dr. Lutaud, of Paris, and he writes me this in reply to my request for the latest statistics.

14787. Is he the author of a work that has been referred to?—Yes, "Pasteur et La Rage." I have the work here.

14788. (*Sir Mackenzie Chalmers.*) What is the date of that work?—1887.

14789. Twenty years ago?—Yes.

14790. (*Dr. Wilson.*) What is the date of the letter?—The date of the letter is the 23rd of April this year: "I was not in Paris during the Easter holiday, and was detained in the country by an attack of 'grippe'; if not, your letter would have been answered long ago. I cannot send you exact statistics for the last two or three years; the numbers I have published at the time of the great Pasteur polemic were demonstrative—viz., that the annual mortality by hydrophobia was not less *since* the Pasteur treatment than it was *before*. For instance, the average number of deaths from 1850 to 1866, date of the introduction of the new treatment, was 30; since the discovery of the new method it was a little higher (about 35 per annum). The system adopted at the "Institut Pasteur" consists in inoculating the virus to everybody having been not only bitten but even licked by a dog without inquiring if the dog was hydrophobic; so they have a lot of customers which are cured of a disease which had not existed. So they establish beautiful statistics to strike the people. The Pasteur Institute is the property of a limited company exceedingly rich, and they can afford to insert advertisements or notes in daily papers; they are regular business people, selling every sort of virus, serums, drugs, even stuff to kill the rats and rabbits. A very rich man, Mr. Ohris, who died recently, has left them 25,000,000 francs. I will try to furnish you with more information, but I am afraid they will come too late." But I have been furnished with that information in the form of a document signed by Dr. Boucher, a well-known man in Paris.

14791. (*Sir William Collins.*) What does that purport to show?—Shall I read it to you?

14792. If you please?—"Before Pasteur's method"—I am reading the translation, but here is the original (*handing in the same*)—"the official statistics collected by Tardieu and Boulay, with the view not of advancing a method, but simply to give an account of the deaths caused by a disease, indicate from 1850 to 1872 inclusive 685 deaths from rabies—*i.e.*, a mean of 30 deaths per annum. After the method when thousands of persons (3,000 patients) were inoculated, whether they had been bitten by mad dogs, or, in the infinitely more general case, whether they were preventively inoculated, the number of deaths, from 1887 to 1890 inclusive, were 154—*i.e.*, 38 per annum. At the present moment it is impossible to get the number of deaths in the whole of France; one entrenches oneself behind the difficulty of picking out the different cases. This excuse has as its true reason the danger there would be for the Pasteurian theories in publishing these statistics, which are more remembered than before Pasteur's method. Yet it is easier to pick out the different cases occurring in the Department of the Seine. The discussions at the Academy, the municipal statistics, render this easy. Here is the result of the comparison between the manifestations of rabies before and after the method. Official statistics before the method, 1876 to 1885: Deaths from rabies 43, a mean of 4 per annum. Ten years after the method, 1897-1901 inclusive: 44 deaths—*i.e.*, 8.8—more than double."

14793. Would that be of French people only?—This applies to France only.

14794. Does it apply to French people only, or does it include those visitors who came to France to be treated?—I do not know. These are official statistics, and it does not specify whether they are French people only, or whether it includes foreigners.

14795. It would be important to discriminate, would it not?—I do not know that it would.

14796. I suppose there was not prior to the Pasteurian period that influx to France for treatment which has been notorious since?—That is so. "I have not the numbers for the years beyond 1901 except the official numbers of the statistics, which are false. One discovers this falseness from a comparison of the numbers furnished by the Academy, and those supplied by Bertillon, Chief of the Statistical Department. Thus:

	Deaths.		Deaths.
Statistics of Bertillon	1897 - - 5	Statistics of the Academy Report to Council of Hygiene	1897 - 6
	1898 - - 4		1898 8
	1899 - - 7		1899 - 9
	1900 - - 9		1900 9
	1901 - 9		1901 - 12

the year 1902 representing one death, after applying to Bertillon 1902 none, 1904 one, express numbers three times less, at least, than the reality." Then he goes on:—"I recall the statistics of Carlo Ruata for Italy. Before the method the mean of the deaths from rabies was about 60. After the method—*i.e.*, from 1887 to 1900—the total of the deaths is 1,193, giving a mean annual rate of 85." That is the result of my application to Luteau.

14797. I gathered from Dr. Martin's reply to Q. 11659 that rabies was regarded as uniformly a fatal disease, and that, according to Bouley, 40 per cent. of those bitten by presumably rabid dogs contracted the disease, whereas amongst those treated by Pasteur from 1886 to 1905 the mortality was in every year less than 1 per cent.?—Because they included cases in which it was not possible to prove that the dogs were mad. That was one of the oldest things I can remember. Youatt maintained or affirmed that of 20 persons bitten by really mad dogs not more than one would develop the disease; that is only a matter of 5 per cent. To put it down at 40 per cent. is a stretch of imagination, I should think.

14798. In hydrophobia has any micro-organism been found as the cause of the disease?—I am not aware of any.

14799. Or has it been claimed by anyone?—Not so far as I know.

14800. In that case is it the fluid that communicates the disease?—It is the saliva of the dog that communicates the disease, and how it happens that the saliva is not the source of the anti-rabic serum I cannot understand.

14801. (*Sir John McFadyean.*) Do I rightly understand you to hold that the experimental method as applied to physiology and pathology has been entirely barren of results?—I have never said so.

14802. But I ask, do you think so?—I suppose I must give a qualified answer to that. I cannot give a definite answer. I have considerable doubts as to the results.

14803. You could not mention to the Commission any case in which you are satisfied that useful knowledge has been obtained by the experimental method in medicine?—I am not aware of any. I have never availed myself of any knowledge obtained in that way that I know of.

14804. Do you think that the same might be said about the other natural sciences, or physics and chemistry. Has any useful knowledge been gained by experiments in those sciences?—Undoubtedly, in chemistry. Chemistry is an exact science. We hear a great deal said about the science of medicine, which is all nonsense. There is no such thing as the science of medicine. Medicine is an art. You might as well talk of the science of painting.

14805. But is chemistry not largely an exact science, because the experimental method has been extensively employed in the investigation of its problems?—Chemistry is undoubtedly an exact science.

14806. Would you tell me why in the case of biology, including physiology and pathology, all methods of investigation except observation should be barren of results?—Because you are not dealing with exact data.

14807. But do you not admit that by experiments you can at any rate limit the data. Would your argument not be fatal against observation as well as experiment?—Not at all.

14808. Can anything be found out about a science which is not exact?—Yes, undoubtedly some things can be found out.

14809. Then you admit that some things can be found out by observation of things as they naturally occur—I mean physiological and pathological facts?—Yes.

14810. How is it that your argument against the experimental method does not apply to observation also. The science still remains an inexact one?—I cannot imagine an inexact science, you know; it is a misuse of the term "science."

14811. Call it anything you like; I cannot find another word handy in my mind that will cover what we both mean. But leaving that out of account you admit that observation has led to the discovery of a great many important facts in physiology and pathology?—Undoubtedly.

14812. And yet this branch of knowledge which you object to being called a science is inexact?—Yes.

14813. Why should one be able to learn something by observation and yet be unable to learn anything from carefully planned experiments?—All knowledge as the result of observation is open to error.

14814. Surely?—Unless you can come to an exact science you cannot rely upon the result of any observation.

14815. You mean to say that even the beliefs which are most firmly held that are founded on observation, may be wrong?—Yes. Take the case of Listerism, for instance. At one time, as you know, Listerism was almost universally practised.

14816. Is this an attempt on your part to discredit observation also?—Yes, it may be taken as such. Everybody, the whole world almost, was impressed with the advantages of Listerism.

14817. I really do not want to go into that?—I take it as an illustration.

14818. Would you forgive me for saying that it does not appear to me to be an illustration of the point which I was trying to elucidate at all. I wanted to learn from you how it came that one might learn a good deal from observation of naturally-occurring cases, but that one could learn nothing, and as a matter of fact in your opinion we have learnt nothing, from observation of experimental cases?—I did not say that we have learnt nothing, but I should like to know definitely what I have learnt as the result of experiment, for at present I cannot recall anything.

14819. You do not come here to give evidence except with regard to diseases of the human subject?—Quite so.

14820. You have no knowledge whatever about diseases of animals?—No, I do not profess to know.

14821. We have had a good deal of evidence laid before us to the effect that things of great practical value with regard to the treatment and prevention of animal diseases have been discovered by the experimental method. You cannot offer any evidence to lead us to discredit that evidence?—No, I am not aware of anything one way or the other.

14822. You make the following statement in your *précis* as explanatory of what the hypothesis was on which the special treatment introduced by Lord Lister was founded; you say:—"The system was founded on the hypothesis that germs, floating in the atmosphere fell into wounds, there developed and multiplied, and produced all the evil effects which sometimes followed surgical operations. In order to combat these lamentable results this system, when it was fully exploited, included operating under an antiseptic spray, and treating all instruments, ligatures, and dressings on antiseptic lines." It seemed to me that in developing your argument you chose to overlook the fact that an important part of the precautions advised by Lord Lister was directed not against atmospheric contamination, but against the contamination that was attached to instruments and to dressings and to hands?—That was not the basis of the Listerian system of antiseptic treatment.

14823. Observe I am quoting from your *précis*?—Yes, I affirm that what I have said there is correct; in fact, you have it from Lister's own address at Berlin.

14824. But I am taking it that you have not misrepresented him?—No, I have not misrepresented him.

14825. You have said that this system, when it was fully exploited, included the treatment of instruments, ligatures, and dressings antiseptically?—Yes.

14826. Does it not appear obvious that it was not directed solely against atmospheric contamination; that the treatment comprised two things? It was directed against what were supposed to be injurious germs in the air; but it appears to have been directed, and I certainly always understood that it was directed against injurious germs that were supposed to be practically ubiquitous and therefore likely to be found on hands and instruments and dressings. Is that not so?—In the early stage of the antiseptic treatment there was no idea of germs or bacteria coming from the skin; it was only of recent years that that was developed, when it was found that no system of antiseptic treatment of the skin could get rid of these bacilli. The staphylococcus albus in the skin is so deeply seated that it is absolutely impossible to remove them altogether.

14827. What do you mean by recent? You said it is only recently; do you mean the last 30 years?—Yes.

14828. That is not very recent?—As it happens, unfortunately, all this matter is ancient history, you know, because it is 30 years since I first began my opposition to Listerism, and that is a quarter of a century ago and more.

14829. I am sorry to say that it is 30 years since I was a medical student myself, but I have a very good recollection that at that time, at any rate, an attempt was made to destroy the hypothetical germs that were on the instruments?—But the main idea was the germs floating in the atmosphere.

14830. Why do you say that that was the main idea, when you admit that the system always comprised the two things?—I believe those were added afterwards. I believe that the first principle was that germs were floating in the atmosphere and got into the wound.

14831. Would you deny that at least 30 years ago, and within five years after Lord Lister's name was associated with this system, he in operating invariably endeavoured to destroy the germs that were supposed to be attached to instruments and hands?—I never got the idea that that had anything to do with Lord Lister's conception in the first place.

14832. But that was especially Lord Lister's practice?—Yes, afterwards; but the first thing that he did was to adopt the spray—that was the basis.

14833. (*Chairman.*) You told me that it was before 1860?—I forget when Lord Lister introduced the treatment. Perhaps Sir John can tell us.

14834. (*Sir John McFadyean.*) No, I cannot tell you. I am really prompted to put these question largely from my own experience. I wanted to know whether you could tell us of anybody who before Lord Lister habitually treated his hands and instruments and dressings with the object of destroying germs that were supposed to be attached to them?—I am not aware of anyone who did it before Lord Lister.

14835. So that the credit of introducing that belongs to Lord Lister?—Undoubtedly; that is the antiseptic treatment as distinguished from the aseptic.

14836. (*Sir William Collins.*) I thought you told me that Semmelweiss did it before?—Yes, cleanliness.

14837. (*Sir John McFadyean.*) You claim to have been rather a pioneer yourself in aseptic surgery?—I had an opportunity of telling the Commission before you came in that in consequence of my opposition to the Listerian method I was twice blackballed by a very distinguished Society in London, and that Sir William Savory and Mr. Lawson Tait and myself were the only men who had the courage to oppose the Listerian method in this country.

14838. But what I meant was that you claim rather to have been a pioneer in teaching that dirt was the thing to be avoided?—Well, scarcely. I think that phrase is due to the late Dr. Campbell Black.

14839. But you quote him with approval?—I quote him with approval, undoubtedly.

14840. Will you tell me what you understand by dirt?—That I have explained already in your absence. My view is that dirt may or it may not contain germs, and that dirt with the absence of germs may poison the wound if it is admitted into it.

14841. What is the chemistry of that sort of dirt?—I cannot tell you.

Mr. George Granville Bantock, M.D., F.R.C.S.ED.

6 Nov. 1907.

14842. It is capable of analysis?—It may be, but I do not know that anyone has ever examined it, and I doubt whether chemical analysis would find out a poison unless it was of inorganic origin. If it was organic the probability is that a chemist could not find it.

14843. It is something so subtle that it is past finding out, you think?—I do not know that it is past finding out, but it would be a very difficult matter to find it out.

14844. Has it not occurred to you that you, or somebody whom you could set to do it, might make himself famous by discovering what is the precise nature of this thing in dirt that is capable of producing the formidable effects with which we are familiar in wounds not treated aseptically?—I have had no ambition in that line to make myself famous by chemical discoveries. I am satisfied to rest upon the results of my practical work.

14845. Do you contend that any sort of what is popularly called dirt is capable of causing suppuration in wounds?—I do not contend for anything of the kind, and I do not see how one can contend for it either. One must prove the absolute product of the application of what is called dirt.

14846. But I understand you to maintain that the great thing is to exclude dirt; that the presence of germs is of little or no consequence; that the dirt must therefore be the noxious element?—To give you an example of that, supposing that a man falls down on the road and cuts his head, and a lot of dirt, take, for instance, sand, gets in without anything else; if you attempt to sew up that wound it will not heal by first intention, simply by reason of the presence of the sand, which is not poison, but which simply produces local irritation.

14847. But may I point out that you are not entitled to draw any such conclusion unless you can give me a sample of this sand or dirt from the street that has not got germs. In discussing whether it is the dirt by itself or the germs that cause the evil, you must not cite a case in which the two are used concurrently?—You can wash a wound and deprive it of all soluble matter.

14848. Deprive it of all the dirt?—Of all soluble matter; but you cannot deprive it of all the sand.

14849. But bacteria are not soluble matter?—But they are washable; they can be removed by washing.

14850. So can the finer particles of dirt?—No; probably the large particles of dirt will be removed, but the small particles will remain, and if those particles be sand you have got a local irritant in the wound, and it will not heal by first intention.

14851. Would you deny that it is possible to inject sand and dirt from the road, provided that it has been freed from its germs, under the skin in considerable quantities without exciting any very serious result?—I think it is very probable that if you inject sand or any inorganic material into a wound it will produce some irritation.

14852. But would you admit that the sand or dirt when treated by any means that can be relied upon to kill bacteria seems to have lost that injurious power which it had in its natural state?—Can you refer me to any experiment of that kind, for I know nothing? There is nothing within my knowledge that would lead me to accept that statement.

14853. You think it is not possible to treat sand by heat, for instance, or by steam, so as to render it absolutely incapable of setting up any serious lesion?—I do not think it is possible, from my experience.

14854. I venture to differ from you. You said that you did not know of any experiments bearing on the matter?—No, I do not.

14855. You have not tried it yourself?—No, and I should not think of trying it either.

14856. On page 6 of your *précis* you say: "It seems very singular that the tetanus bacillus, which is believed to be the sole cause of tetanus or lockjaw, should be found so abundantly in manured or garden soil, or on the surface of roads fouled here and there with horse-droppings." I was not able to follow that reasoning. What is singular about it?—That the disease should be so rare while the presence of the bacillus is so common and so almost universal; that is singular.

14857. But does not that cease to be singular when one adopts the view that the tetanus bacillus is harmless except when it is introduced into the tissues through a wound. What is singular about that theory?—How do you account for it—if you will excuse my asking you a question—for the occurrence of tetanus after an ovariotomy, for instance? Can you explain the like of that?

14858. Certainly?—Do you mean to say that that is because the tetanus bacillus has been introduced into the body?

14859. If you operated, or any of those who hold the same views as you do, I should think it a perfectly natural consequence to happen, now and again at any rate, because you omit the only precautions which can ensure that tetanus will not set in; and even supposing that you adopted the precautions which are generally advised, it is not contended by anybody that there might not sometimes be a loophole which allowed the tetanus spore to creep in?—That is all assumption.

14860. That is the best answer that I can give to your question?—Very good; it must be taken as assumption, but not as evidence.

14861. What is there remarkable, may I ask, in the fact that the tubercle bacillus is not found in the sputum in the early stage of the disease?—I stated that to show that the tubercle bacillus is not the cause of tuberculosis.

14862. Is that the only evidence that you have got to show that it is not the cause of tuberculosis?—I think that is sufficient; it ought to satisfy any mind.

14863. Is it not perfectly natural that the tubercle bacillus should not be found abundant in the sputum, at any rate until the lesions which it has caused begin to break up?—But it is not found at all.

14864. Who said that?—Many people have said so.

14865. But I think that a great many people say that the bacilli are found?—I have read as much as I have seen on the subject, and I have never met with a man yet who has said that he has found the tubercle bacillus in the sputum before necrosis of the tissues has taken place—that is to say, in the early stage of the disease. It is denied by men of considerable authority on the Continent. I do not know whether there are any in this country who deny it.

14866. Yes, I think a good many deny it, and I think myself it is entirely contrary to the fact. You are familiar with the chain of evidence on which it is held that particular bacteria are the actual cause of disease. You are familiar, no doubt, with the evidence which Professor Koch produced many years ago to prove that what has since been called the anthrax bacillus is the actual cause of anthrax?—I have never paid any attention to the question of anthrax; I know nothing at all about it; but if I were asked for an explanation of the occurrence of anthrax I should say that when an individual suffers from anthrax, the active poison of anthrax has somehow been introduced into his body. I hold the same view on that question as I do on tuberculosis, and on other diseases which are attributed to the action of bacillus.

14867. But that is hardly going into the matter as minutely as I wanted. If you are not familiar with the evidence on which it is held that the anthrax bacillus is the cause of anthrax, I will briefly tell you what it is. It is that when you get a case of anthrax you can find this thing which is called the anthrax bacillus generally in enormous numbers, that you can induce this organism to grow outside the body in a great variety of artificial solutions of a comparatively simple character, and you can go on cultivating it and transfering it from one tube to another for years, and whenever you like you can produce what appears to be a case of anthrax exactly similar to the original natural one by injecting a little of this culture under an animal's skin. It dies, and it is just like the original case. It has this anthrax bacillus in its blood. When that can be done repeatedly, will you point out where is the fallacy in concluding that the bacillus is the cause of the anthrax?—In the first place the bacillus has not been freed from the medium in which it lives.

14868. Allow me to interrupt you by saying that it has been freed from the medium in which it lives many and many a time?—Washed and absolutely freed?

14869. You can wash it repeatedly for days, and it will still be found to have the same effect?—And when

it comes to the period of injection, do you inject the live bacteria or the fluid?

14870. You can inject the solid bacteria and nothing else?—Because you know in the case of Koch's fluid there are no living bacteria introduced at all.

14871. Nobody has pretended that there are any in tuberculin, so far as I know, but let us stick to the case of anthrax, or if you like take tuberculosis. You can cultivate this thing called the tubercle bacillus, and can carry it on for years and years thousands of miles away from any case of tuberculosis; you can wash it as long as you like, and you can introduce it into an animal and you set up what appears to be an ordinary case of tuberculosis. What is the fallacy in concluding therefore, when that is done repeatedly, that that thing which is called the bacillus of tuberculosis is the actual cause of the disease?—With regard to anthrax I know nothing at all about it, I have not studied the subject; and in the case of tuberculosis, so far as my reading and observation go, the introduction of the tuberculin was not the introduction of a living bacillus, and I am not aware of any experiments in which a live bacillus has been introduced, freed from the medium in which it lives.

14872. You think that that has not been done in any other instance either?—I do not contend for anything beyond what I know. I am not aware of any experiments to that effect.

14873. Would you deny that cases of tetanus have often been experimentally produced by using the organisms freed from their liquid surroundings?—I could not deny anything if it is stated as a positive fact. I am not prepared to deny what is stated as a positive fact.

14874. (*Mr. Ram.*) In the event, might I ask you, of your being satisfied of the introduction of such an active actual bacillus, and that the consequences were that it produced tuberculosis, or anthrax as the case might be, would that modify the views which you have been expressing to us to-day?—I should have to be satisfied that the bacilli alone were introduced and not the medium.

14875. I am supposing that to be the case. If you were satisfied of that—that they introduced the actual bacillus—would that modify all the opinions that you have been expressing to us to-day?—Probably, yes. I think if that were shown to me to be an actual fact, I would accept it as a fact, but there are so many theories.

14876. (*Sir John McFadyean.*) You contend for the existence of what is called a materies morbi as distinct from bacteria, and you apparently contend that when you get noxious effects from injecting cultures of bacteria it is something in the liquid that is to be blamed?—That is my view.

14877. Has this something in the liquid the power of multiplication?—Probably, as in the case of smallpox.

14878. You think that you can really figure to yourself a non-living liquid material which has the power of indefinite multiplication?—Undoubtedly. Smallpox is an example; vaccine is an example.

14879. You are begging the question?—I do not see it.

14880. In a very flagrant way, because it is contended that in all probability the materies morbi in vaccinia is a bacterium?—You say in all probability, but that is not a fact.

14881. I never said that it was. I said that it was a fact with regard to many other diseases, tuberculosis, anthrax, and so on, and it may yet be made a fact with regard to vaccinia?—But you have no right to calculate upon a possibility. You may calculate to some extent upon a probability.

14882. But I contend that it is a fact with regard to many other diseases. This same thing, whatever it is, has got a far greater power of multiplication in anthrax than in vaccinia or in variola?—I do not know how that is possible.

14883. Are you familiar with anthrax in animals?—I know nothing about anthrax.

14884. Would it surprise you to know that if you inoculate an ox to-day it may be dead in 48 hours, but the thing has multiplied to such an extent that every drop of the animal's blood if injected into another ox would kill it with anthrax?—That may be; that is analogous to the case of small-pox.

14885. Then that involves that during the morbid process what has been multiplying is not the bacterium, but some chemical liquid?—Some liquid. We will not call it chemical or anything else; but it is an unknown liquid.

14886. (*Sir Mackenzie Chalmers.*) Is there any known chemical poison which multiplies in the human body?—No, certainly not. The chemical process applies chiefly to inorganic matter; it does not apply to organic matter. There is something else introduced in the case of organic matter which is absent in the case of inorganic matter; that is vital force—life.

14887. Take the case of a vegetable poison, that is organic?—That is organic.

14888. Is there any vegetable poison that multiplies in the human body?—No. That is a very different thing from poisons existing in the human body. It is a totally different thing.

14889. But there is no instance of either an inorganic or vegetable poison which when introduced into a wound multiplies in the human body?—No.

14890. (*Dr. Gaskell.*) By multiplication or growth in the human body, do you mean necessarily something living?—Yes, apparently. Take the case of small-pox. You know that if you introduce an infinitisimal portion of the fluid under the skin you have an enormous multiplication of the actual poison, which is an exact repetition of the poison that you introduced under the skin.

14891. (*Mr. Ram.*) Which involves something living?—It involves a living subject.

14892. Exactly?—If you put it under the skin of a dead subject there will be no effect.

14892 (A). No, I mean does the multiplication, the growth, involve something living?—It involves the life of the subject.

14893. I do not mean that at all. You say that the multiplication, the growth, is not a chemical process; there is no evidence of connection with vegetable alkaloids. By that word growth, do you necessarily imply that the morbific material must be a living substance?—I do not know what it implies. There is a fact that you cannot explain.

14894. Can you have growth without life?—You must have the life of an individual. In my ignorance I call that a chemico-vital action, because you require a living subject in which this poison may be developed.

14895. (*Sir John McFadyean.*) But I submit that it is not quite fair of you to say that there is a fact which you cannot explain, because a minute ago I took an absolutely analagous case—namely, anthrax—in which there is the same apparent enormous rapid multiplication of something, and I put before you the chain of evidence on which it is held that it is not the liquid that multiplies, but that it is the thing which we call the anthrax bacillus, and you were unable to break down that chain of evidence?—In the case of anthrax I say that I do not know anything at all about it, but I stick to the case of smallpox, in which you have not shown the existence of any organism.

14896. But you also have not shown that there is not an organism there?—It is for you to show that there is an organism. It is for me to deny the existence of it until you can prove its existence.

14897. (*Sir John McFadyean.*) On page 7 of your *précis* you refer to this question of the rapid evolution of the morbid process in vaccinia or smallpox, and you say that it is an extraordinary state of things that this should be due to the action of a special form of bacillus which passes your comprehension and is incredible. That is going far further than saying that it has not been seen. You say that it is not credible. Again, I put to you the case of anthrax, which is one on all fours, and which you agree is not incredible. I have given to you the facts on which it is held to be proved, and you yourself admitted that you could not point out what the fallacy was. If it is true in anthrax, why should it be incredible in the case of vaccinia, if one merely assumes that the thing has been overlooked—that our methods so far have not been capable of detecting this thing—it may be too small for one thing?—But you have no right to assume its presence or its existence until you can prove it.

Mr. George Granville Bantock, M.D., F.R.C.S.ED.

6 Nov. 1907.

14898. Not even by analogy?—No, not even by analogy. Analogy is a very unsafe thing to go by.

14899. Then on page 8 you discuss what happens in a patient affected with smallpox, including the fact that the patient generally becomes insusceptible to a second attack, and you say: "No one has offered even a plausible explanation." Do you think that is quite fair. Have you read the recent literature on protective inoculation and vaccination?—I am not aware that any observations have shown the mode by which this change is brought about or the nature of the change that is brought about as in the case of vaccinia or smallpox.

14900. Remember, please, that you are not the first scientific witness before the Commission?—I do not profess to be a scientific witness. I profess to be a practical witness.

14901. What I want to point out to you is that theories as to how this is brought about have been placed before the Commission?—Quite so.

14902. And it seemed to me to be rather too strong language to tell the Commission that these theories were not even plausible?—In my opinion. I am only expressing my own opinion, and I have a right to express my opinion on any subject.

14903. (*Sir Mackenzie Chalmers.*) I do not want to go into technical details; I only want to know whether I rightly appreciate your argument, because you have gone into some rather technical matters. You said that medicine is not and cannot be an exact science?—Quite so.

14904. It is a practical art?—Yes.

14905. Do you therefore go so far as to say that it has not made any advances towards being an exact science?—It never can, because in the first place we do not know what life is, and we are deprived of one of the most important premisses. It is absolutely impossible that medicine can become a science.

14906. Would you treat it practically then as a handicraft?—It is an art and a very empirical one too.

14907. Is not that almost going back to the old days of surgeons and barbers?—I do not know that it is. We have learnt by experience. We are trading in fact upon the experience of ages.

14908. But we are not making any scientific progress; we are only building up empirically?—Building up facts.

14909. But when we are building up facts, as it builds up facts does not an art tend to become a science?—Not a bit of it.

14910. When you generalise from facts and arrive at even an intermediate law, is not the art becoming a science?—Not a bit of it. I could give you plenty of illustrations.

14911. If I have understood your argument aright, you agree that in certain specific communicable diseases you have concurrently specific bacilli or micro-organisms?—For example?

14912. For example, anthrax and Malta fever?—In Malta fever that is not proved to demonstration yet.

14913. I understood you to say that there were certain specific micro-organisms or micro-cocci or bacilli; that with these specific infectious diseases you do in many cases find these specific bacilli?—Undoubtedly, and I say they may be characteristic of the disease, but they are not the cause of the disease.

14914. They are either concomitants or inseparable accidents, as the logician would say, or they are caused by the disease, instead of causing the disease?—You might just as well argue that a river is the result of trout being in it or salmon.

14915. Therefore you say that cause and effect have been transposed by the bacteriologists?—Yes. In some rivers you will only get trout and salmon; in other rivers you get other fish, such as dace and those fish that live in still water, where salmon and trout will not live. And in the same way you have grouse living on moors, while you have partridges living in arable fields, and so on.

14916. But they are not the cause of the fields?—Just so.

14917. (*Sir John McFadyean.* But you can get the fields without the grouse and the rivers without the salmon?—Yes, that is just it. You have got the disease without the bacillus. That is all right.

14918. (*Sir Mackenzie Chalmers.*) Have you followed carefully the researches of bacteriologists; do you read their literature carefully?—I have got so sick of the matter of late that I have not done so.

14919. For how long have you not done so—for eight or ten years?—More recently than that. I have paid some attention to the matter.

14920. But you have not studied carefully recent researches?—No.

14921. You think it is a waste of time?—Yes, quite so, because my work has been the practical work—the work of a surgeon, and I have never found any benefit from bacteriology.

14922. It is interesting to ask, is there any large body of medical opinion holding the same views as you do?—I do not know. But you know at one time I was in a minority of three against millions.

14923. *Athanasius contra mundum?*—Yes, and I was accused of that the other day in a letter in the "Medical Press and Circular," because I denied the occurrence of tuberculosis as the result of drinking milk. I asked for one single, solitary instance in which it could be shown even that there was a suspicion that the disease had been thus communicated, and the writer said it was a case of Dr. Bantock *contra mundum.* I pointed out to him that that was the position that I occupied some quarter of a century ago when I began my attack on Listerism.

14924. And now the *mundus* has come round to Dr. Bantock in that respect?—On the question of Listerism undoubtedly, and I do not get the credit for the part that I played in introducing the so-called aseptic system or the system of cleanliness; but yet there are some, who are not prejudiced, who admit the part that I played in bringing it about. As you know, Listerism now is as dead as Queen Anne.

14925. I want to come to another point, please. You mentioned the case of smallpox. Do you hold with the protective effect of vaccination?—I do, as the result of experience.

14926. As a mere matter of accumulated experience?—Yes.

14927. Do you see any objection to using animals for the purpose of providing vaccine? Do you think it is justifiable?—I have myself vaccinated a calf, taken the lymph from that calf, and vaccinated children with it, but that is the only thing I have ever done in the way of experiment.

14928. We may take it generally that you have come here on the recommendation of an anti-vivisection society?—Will you allow me to say, with which I have nothing at all to do.

14929. I only wanted to know how far you and they agree except upon one point. Do you think it is justifiable to use animals to prepare vaccine—you do?—I have no sentiment in the matter of experiments upon animals. With me it is a question of utility, and if I can be shown that certain experiments are valuable in increasing our knowledge I have no objection to them. I do hold some objections which perhaps will come out in my examination.

14930. Let me take you to another thing. You have told us a good deal about diphtheria; have you had any experience with the antitoxin?—No.

14931. Do you think its use is justifiable or unjustifiable?—It may be justifiable, but it has yet to prove its usefulness.

14932. Have you seen cases treated with the antitoxin?—I have not, and I should not think of treating a case with the antitoxin.

14933. You would not use it yourself?—No, I should not.

14934. But in the case of people who believed in its beneficial effects, do you think that they are justified in using animals in preparing the antitoxin?—It does not matter to me how the antitoxin is prepared. If it can be shown to be useful I would admit its use, of course.

14935. I want to go one step further. A good many new drugs come into use. Do you think it is justifiable before those drugs are tried on human beings to try them on animals?—Whether it is justifiable or not, I would say that in my opinion it is useless. I am inundated with new remedies every year, a thousand and one—"The Arabian Nights" was nothing to it—and scarcely one of these remedies that are so much vaunted is of any use.

14936. That is very likely?—And these drugs, mind you, as I understand, are sent out on the faith of certain results obtained by experiments on animals, not on the human subject.

14937. Surely among a thousand drugs, you may every now and then get one which is of great use?—As I have said, I think the thousand and oneth is the only useful one; and even in the case of those that are useful their application is very limited. A number of them were mentioned here by a witness—veronal, trional, sulphonal, and some other things with names as long as your arm, but none of those things are of any use. I have tried several of them, and they are absolutely useless, if not dangerous. Sulphonal, as you know, is a dangerous remedy because it is cumulative.

14938. I only wanted to get a general principle from you, to know what your opinion is. You think that researches in pharmacology are useless?—Yes.

14939. And it is better to stick to the old familiar remedies which we know, on the whole?—The longer I live the more I am reduced in the number of my remedies, until I can now count them on the fingers of my two hands. And there are fallacies about old remedies. Many of the old ones you will find, if you investigate them, are perfectly useless. So that as I say I can reduce the remedies that I use now to the number of fingers and thumbs that I have got.

14940. That simplifies medicine, does it not?—Immensely.

14941. Did you read Dr. Cushny's evidence given before this Royal Commission?—I fancy that I did, but I do not remember the trend of it.

14942. He gave evidence on the usefulness of animal experimentation with new drugs, and he drew the conclusion that it was of great benefit. I do not know how far you agree with him?—I do not agree with that. And I think Sir Lauder Brunton gave evidence to the same effect.

14943. He did?—I do not agree with that at all.

14944. Did you read Sir Lauder Brunton's evidence?—I did.

14945. You disagree with his conclusions?—Undoubtedly, particularly on the question of surgery.

14946. On the question of physiology, do you think that physiological experiments on animals are justified or not justified; do you think that we can learn anything from them?—I doubt it very much.

14947. Do you think that we ever have learnt any thing from physiological experiments?—I am afraid not. I am afraid we have not got any knowledge gained by observation beyond the case of Alexis Martin. I do not think we have got beyond that.

14948. That was at the end of the eighteenth century, after the Canadian war?—It was a long time ago anyhow. I think the date has been given in someone's evidence.

14949. May I take it, then, that the very numerous physiological experiments on animals since then have taught us nothing?—I think so; that is my opinion.

14950. You mentioned one other matter that I should like to ask you about; you mentioned the theory that plague was communicated by means of the rat flea as the mechanism of communication?—Yes.

14951. Have you read the two reports of the Plague Commission?—No, I have not.

14952. I am sorry that you have not, because the arguments to a mere layman seemed sound, and I should like to know where the fallacies were?—Well, there was one piece of evidence given before this Commission quite recently which freely excited my risible faculty to a very large extent. It was that when the experimenter was engaged in collecting fleas from the rats he wore top boots. I think when it comes down to that we have got the *reductio ad absurdum*.

(*Sir John McFadyean.*) The Commission must be devoid of a sense of humour, then.

(*Witness.*) I think that is in Dr. Martin's evidence.

14953. (*Sir Mackenzie Chalmers.*) Did you read his account of the experiments themselves, and the way in which he tested his theory?—No, I am afraid I did not, for as I say, I am rather sick of the thing.

14954. I may take it that you did not read the actual experiments?—No. I quoted the evidence obtained in India, where it was shown that patients who had died from plague presented no bacilli in the body. I stated that Mr. Hankin, Chemical Examiner and Bacteriologist for the North-west Provinces and Oudh, reported to the Plague Commission in 1899 that there was no doubt that cases of plague occurred among human beings in which no microbes were visible at the time of death; and I think that an actual observation like that is worth any amount of theory.

14955. There were also experiments made on the opposite side by Dr. Charles Martin on one day, were there not, where he excluded the flea and the animal did not take the disease; but where the flea got access to the other animal, the other animal did take the disease?—But it is absolutely impossible to ascertain all the conditions that surround a case of that kind, and unless you can do that, you cannot rely upon the observations.

14956. As you have not read the observations, I do not think there is any use in discussing it?—No, I do not think so.

14957. (*Mr. Ram.*) Do you think that the fact that it is impossible on certain occasions—say, in these cases of plague—to discover the bacilli in the patient, warrants you in saying that there is no such thing as a bacillus?—No, but what I maintain is, that it does not warrant the supposition that the bacillus is the cause of the plague. That is my argument.

14958. If there is a failure in certain cases to discover the bacillus, that does not preclude the discovery of the bacillus in other cases?—Certainly not.

14959. I think you have told us that many years ago you formed a strong opinion against what I may call the bacillus theory?—Quite so.

14960. And that for several years past, at any rate, you have not even read the researches made by others in the matter?—Quite so.

14961. And you have never yourself performed any experiments with the view of ascertaining the presence of bacilli or otherwise?—Never; I have never bothered my head about it.

14962. You know that we have had witnesses before us who have spent the whole of their lives in such experiments as these, and many witnesses of great distinction have laid before us evidence which, in their opinion, at any rate, warrants them in thinking that they have discovered the actual bacillus in the case of certain diseases capable of communicating the disease. Do you ask us to reject all that evidence in favour of the opinion of one witness who has never experimented, and has not lately even read the researches about the matter?—I ask you to accept my opinion for what it is worth. I am a practical man. I have been engaged in surgery for more than a quarter of a century, and my views are the result of practical work and observation in that work, and as the result of that I have come to the conclusion that the bacilli play no part in the causation of disease. They may be associated with the disease, and they may even be a characteristic of the disease, but they are not the cause of the disease.

14963. I think you told me just now, very candidly, that if you could have brought to your knowledge the fact that the undoubted bacillus by itself, apart from the surrounding fluid, on being injected into an animal caused the disease, that would lead you to modify all your evidence?—I would not say positively that it would.

14964. Then what is your attitude of mind with regard to that?—I cannot say. I should have to know all the circumstances, all the conditions surrounding the experiments, before I could give my adhesion to any particular doctrine.

14965. The case which I am putting to you is the case which has been very frequently put to us—that of the bacillus of some disease separated from any surrounding fluid, washed repeatedly, isolated, if I may so say, so as to be the bacillus pure and simple, injected into the blood of an animal, and causing imme-

Mr. George Granville Bantock, M.D., F.R.C.S.ED.

6 Nov. 1907.

Mr. George Granville Bantock, M.D., F.R.C.S.ED.

6 Nov. 1907.

diate symptoms exactly identical with the disease of the person from whom it originally came?—Well, I have considerable doubt as to whether that has been done or not—whether the bacilli have been deprived of all the material by which they are surrounded. I say I have considerable doubt as to the absolute success of the cleansing process.

14966. But when you say you have doubt about it for many years, at any rate, you have not taken the slightest pains to find out what has been done in the matter?—No, I have not, and I do not profess to give any opinion on that subject. I have been so satisfied with the evidence that I have had, that I have ceased to take any trouble in the case of bacilli.

14967. Your evidence and such experience as you have had (and I know that it has been very large indeed, and very successful) have been entirely on the human subject?—Yes.

14968. And you have made no sort of experiments with the view of ascertaining the existence or non-existence of any bacillus?—Quite so.

14969. Now, with regard to this aseptic or antiseptic treatment, you have said that you were one of the pioneers of that which is practised so much now—namely, the protective measures taken by being cleanly?—Yes.

14970. By being cleanly, do you mean anything more than merely the use of water?—And soap.

14971. Against what do you guard when you are cleanly?—Dirt; and that is the only explanation I can give you.

14972. And what in dirt is it that you desire to guard against?—I do not know, nor does anybody know.

14973. You think that if you were not cleanly you might infect the patient with some disease with which you had been recently in contact?—Yes, undoubtedly.

14974. There is a something which some people call germs and other people call bacilli——?—Not generally so.

14975. May I finish my question? Am I right in thinking that there is in dirt a something which some people call germs and some people call bacilli, and of which you say that you do not know what it is, against which you wish to guard?—Undoubtedly.

14976. And against which, if you did not guard, you might infect the patient?—Quite so.

14977. You told us of the case of some surgeon who in old days went to a man who I think you said had been operated on for hernia. He inserted his finger into the wound; the wound was suppurating. He then merely wiped his finger on a cloth or towel, and he afterwards inserted the same finger unwashed into the body of another patient?—Yes.

14978. In your opinion was that a dangerous thing to do?—Under the circumstances it was not a dangerous thing to do, because the two wounds were in the same condition; but if he had gone to the first case and just wiped his finger and then gone and performed a fresh operation and allowed some of that material to get into the wound, then I should look for disaster. But the two wounds were in the same condition.

14979. So that the only safeguard was in the condition of the patient and not in the care of the surgeon?—Yes.

14980. Supposing that the second patient to whom he had gone was a patient with a clean uncontaminated wound, what would he have given to him?—Inflammatory mischief, followed by suppuration and goodness knows what.

14981. Why would he have given it to him?—Because he would have introduced some poisonous material apparently into the wound and otherwise dirt.

14982. He would have wiped off, by the process that you have told us, anything in the nature of fluid?—Not all of it. He would get some of it under the nail, for instance.

14983. And you think that that fluid might produce very serious consequences?—Yes.

14984. Why is it easier to suppose that the fluid would cause mischief than to suppose that in the fluid there would be a bacillus that would cause mischief?—You must prove that the bacillus was there first of all.

14985. I do not think that that is quite an answer to my question. I should be glad to have an answer to it?—Will you kindly repeat it?

14986. Certainly. Why is it easier to suppose that the fluid, as you have just told me, would cause mischief to the second patient, than to suppose that it was a bacillus communicated by the finger which was the cause of mischief?—Because the fluid is visible to the eye and you know the fluid is there, but you do not know that there are any bacilli in it; and, as we know, in the case of a chronic ulcer the application of the active staphylococci is of benefit to a wound that is not healing up well.

14987. But are there not thousands of cases in which things which are invisible to our eyes are most undoubtedly potent factors of either good or evil?—But how can you speak of them as being potent factors if you do not know that they are there? You only suppose that they are there.

14988. If you take a tiny drop of what you have been speaking to us about—from a vaccine pustule—and you put it into the body of an animal or a man, it produces vaccine?—It reproduces itself; it does not produce septicæmia.

14989. And you suggest that it is because we can see this tiny drop that it produces it. What does it matter whether we can see it or not?—It does not matter; all you want is to know that you put it there. It does not matter whether you see it or not. But you know that you put it there. You take it on the point of your lancet and introduce it.

14990. You are so confirmed in the view that you hold that there is no such thing as a bacillus being the cause of disease, that you think there ought to be no further research into the matter at all?—I am very much of that opinion.

14991. That is not the method by which medicine and many other sciences in the past have made advances?—I am not aware of the influence which these experiments have had upon the advance of practical work.

14992. But you have told us that you have not latterly, at any rate, tried to inform yourself?—No.

14993. Still, you think that no research as to the nature and method by which disease is communicated is advisable?—I would not go so far as that.

14994. Then how far do you go?—I would simply go to the limitation of experiments. I am not an opponent of vivisection. I might say that I should be almost sorry if vivisection were abolished, because it may be useful yet. It has yet to be proved that it has been of material service, but it may yet be so. The only opposition that I should offer to vivisection would be that operations should not be performed before a class—that experiments of which the results are already known ought not to be repeated; and that experiments with a view of ascertaining the action of remedies ought to be very much curtailed. That is the extent to which I should go.

14995. I am much obliged to you for the answer. I think it helps us very much, having regard to what we here have to investigate.

14996. (*Dr. Gaskell.*) On page 3 of your *précis* you give Lord Lister's words: "Hence I was led to conclude that it was the grosser forms of septic mischief rather than microbes in the attenuated condition in which they existed in the atmosphere, that we had to dread in surgical practice." Do you intend us to believe that by those words Lord Lister meant something that was not living germs?—I do not know what he meant. You must apply to Lord Lister himself for the meaning of his words.

14997. I heard the lecture myself; I was there?—This is taken from the report of his lecture as published in the "British Medical Journal."

14998. I know it. I was there at the time in Liverpool and heard it?—But one might make a mistake in one's recollection of a thing; but one cannot make a mistake in copying down the exact words of the address, and that is what I have done here.

14999. But I want to be quite certain that you do not want us to believe that that term, "the grosser forms of septic mischief," in any way implied that Lord Lister had given up the germ theory?—I cannot answer that question. I do not know what his ideas were. He gave up the idea that the spray could be of any use in affecting germs floating in the atmosphere.

15000. But in saying "the grosser forms of septic mischief" he was putting that against the next sentence, "the attenuated condition" of microbes in the atmosphere?—He said: "Hence I was led to conclude

that it was the grosser forms of septic mischief, rather than microbes in the attenuated condition in which they existed in the atmosphere, that we had to dread in surgical practice." What is the meaning of "the grosser forms of septic mischief"?

15001. Throughout the whole of his lecture was it not the case that he dilated upon the influence of the germs in producing suppuration and disease, which were "the grosser forms of septic mischief"?—I forget what he said throughout his lecture. That was the part that interested me, because it had a direct bearing on my own practice.

15002. But nobody who listened to that lecture could doubt for a single moment that Lord Lister meant throughout to hold on to the germ theory of disease?—At the same time I should just like to point out to you that Lord Lister certainly said at Liverpool that the condition was one of great importance; that it was not the germ or the bacillus alone, but that it was the condition necessary for the action of the bacillus.

15003. There was another point, too, that I wanted to be quite clear about, which you did not seem to me to make quite clear when Sir William Church asked you a question. You said, speaking of the microbes of tuberculosis, that we now know that air, light, and sunshine favour their growth. I do not understand about that "now know"?—As the result of experiments on sewage we now know that if you expose the sewage matter to the air it favours the action of the microbes.

15004. Then you refer in that "now know" to microbes in sewage, and you are not referring to the microbe of tuberculosis?—But it applies throughout.

15005. Does it apply throughout?—Yes.

15006. (*Sir John McFadyean.*) By analogy?—Yes.

15007. (*Dr. Gaskell.*) You have no experience that there is some difference, that some microbes like light and some microbes like dark?—I am quite aware that some flourish more in light and some in dark.

15008. And are you not aware that some will be actually killed out by exposure to light and sunshine?—No.

15009. You are not aware that there is a great difference in microbes in that respect?—I am not aware that they are killed off, for instance, when they get into a river and are exposed.

15010. (*Sir William Church.*) I understood you to say in answer to me that you distrusted those experiments in which bacilli were exposed to light and air, because they were done under unnatural circumstances?—Unnatural conditions.

15011. And I ventured to use the term that the very fact of their being in captivity was unnatural. Therefore, if you consider that an unnatural circumstance, you doubt all these experiments?—Yes.

15012. (*Dr. Gaskell.*) You have not seen any experiments of the kind?—No, none.

15013. They are very striking?—To some minds.

15014. I wanted to be clear, if I could, with respect to this fluid that accompanies the microbes, and which, when injected, reproduces itself, and so causes disease. That I understand is your position?—No, I have not said that.

15015. That it is something in the fluid?—I have not said that. The only instance that I have given of a reproduction of itself is in the case of smallpox. I have not said anything about the fluid of diphtheria reproducing itself.

15016. What I wanted to understand more clearly than we have yet obtained, was what is meant by the words "reproduces itself." All bodies can be put into two categories, either living or non-living. A living body we know reproduces itself. I do not understand what you mean by a non-living body reproducing itself, therefore when you use the term "reproduce" do you mean a living substance or a non-living substance?—You mean an organism or a substance.

15017. A living substance or a non-living substance?—I have made use of the word reproduction in the case of smallpox for this reason: that when you introduce an infinitesimal portion of the contents of a vesicle under the skin you have an enormous multiplication—call it multiplication or reproduction, whichever you like—of the poison; it is incalculable.

15018. I do not understand what you mean. If it was a salt in water, of any kind whatever, would there be that enormous reproduction?—Certainly not; I doubt whether there is any reproduction in the case of snake poison. We do not know the action of snake poison; we do not know how it acts upon the blood, whether it is multiplied or whether the initial dose is sufficient to destroy the blood and kill the subject; but we do know in the case of smallpox, because we can get any quantity of poison possessing precisely the same properties. There is no analogous condition, that we are aware of, to that of smallpox.

Mr. George Granville Bantock, M.D., F.R.C.S.ED. 6 Nov. 1907.

15019. Do you not rather mean by its reproducing itself that it may possibly be a spreading of the small thing rather than an increase in quantity? Snake poison is the spreading possibly of the initial poison that is put in?—Spreading throughout the body.

15020. Carried about in the blood and fluids?—Yes.

15021. Do you not mean that that is what happens with each vesicle?—No, I do not think they are at all analogous. I think that there is no resemblance between them. Smallpox and vaccinia, which are probably the same thing, stand by themselves; there is nothing else like it in Nature.

15022. Now I have got it. Then it is a process of reproduction which is dissimilar to any other in Nature?—Undoubtedly, but no one can explain the nature of it.

15023. I understand you to suggest to us that if you have a fluid in which certain organisms, bacteria or microbes, are found, in your opinion the mischief is done by the fluid parts of that fluid rather than by the microbes themselves?—Undoubtedly.

15024. How would you test it? If you separated the fluid from the microbes would you expect the mischief to be done by the injection of the fluid part or by the injection of the part that contains the microbes?—I should say by the injection of the fluid part most likely.

15025. Are you aware that there is such a thing as a Pasteur filter which prevents these small microbes passing through?—I am not aware that there is a filter which will prevent microscopical objects from passing through.

15026. It is so; it has been shown again and again?—Well, of course, if you say that it is so, I am not prepared to say that it is not so.

15027. In that case if it was possible to do that you would expect the fluid part to give the disease rather than what is left behind?—Yes, that is what I should expect.

15028. You are not aware that that experiment has been done over and over again with just exactly the opposite result?—I am not aware of that.

15029. Would you tell me what is a trypanosome?—I do not know anything about it.

15030. You have never heard of it?—I have already said that I do not know anything about sleeping sickness or the cause of it.

15031. But you said that the tsetse fly developed its own poison?—Yes.

15032. Did I rightly understand you to mean that in the case of both nagana and sleeping sickness it was the poison of the tsetse fly that gave the disease?—I am not aware that the tsetse fly is the cause of that sleeping sickness. I know that it has the effect of killing horses and cattle in certain districts, but beyond that I am not aware that it has any influence upon the human subject.

15033. In the case of killing horses and cattle, I understood you to say that it was the poison that the tsetse fly developed that killed them. Is that your opinion?—In certain districts of Africa the tsetse fly kills horses and cattle, but I have never heard that the tsetse fly produces any effect upon man. If you read Gordon Cumming and Livingstone, and all those earlier explorers, who tell us everything about the tsetse fly, we never hear anything of sleeping sickness or any disease communicated to the human subject.

15034. Is it your opinion that it is the poison produced by the bite of the tsetse fly that kills those animals?—I believe so most thoroughly.

15035. You are not aware of anything to the contrary?—No.

Mr. George Granville Bantock, M.D., F.R.C.S ED.

6 Nov. 1907.

15036. In fact, you know nothing about trypanosomes?—I will not allow that I know nothing about them, because I have read extensively the writings of Gordon Cumming and Livingstone and other explorers who have told us about the ravages of the tsetse fly on horses and cattle, but not on human beings. Human beings were not attacked at all.

15037. If you or any of your friends were bitten by a mad dog, would you go to Pasteur?—Not a bit of it.

15038. You would not give him a chance?—No.

15039. You gave us some statistics with regard to hydrophobia. Those were all general statistics were they not?—No, they are very specific.

15040. They are statistics as to the number of deaths in certain times?—I think those statistics are specific, because they refer to particular times, and to a particular district of France.

15041. But they were general statistics, they were not case statistics?—They were not case statistics. I do not consider that the giving of cases is a statistical statement at all.

15042. When you first performed surgical operations for ovariotomy would you have considered it fair to you that the general statistics as to deaths from ovariotomy should apply also to your case?—No, certainly not.

15043. Would you not have felt very much aggrieved if it had not been a case there of case statistics rather than general statistics? Would you not have considered it unfair unless the person who drew up the statistics had said, Dr. Bantock has had so many cases of ovariotomy, and has had only so many deaths?—General statistics, lumping together the statistics of half a dozen operators, would be absolutely useless. What you wanted to ascertain in the earlier stages of the operation was what was the success obtained by any particular operator, and what was his method of operating.

15044. Is not that what you want to obtain with regard to the Pasteur Institute and hydrophobia?—I do not see the analogy.

15045. And not the number of deaths that took place in a certain year throughout France?—I think if you can show that there was a certain number of deaths during a certain number of years before the introduction of the Pasteurian treatment, and that the deaths had not been reduced over a similar number of years after the introduction of the method, that is a fair comparison.

15046. Would you like that sort of comparison to have been made in your own case with ovariotomy. I should not have liked it if I had been you?—I should not like my cases to be compared with the results of anybody else certainly, but I am quite open to have my results in a certain number of years compared with the results of another number of years. I think it would be very unfair to credit me either with the successes or the failure of any other operator. I must stand on my own feet.

15047. (*Dr. Wilson.*) With regard to that, of course, in dealing with cases of ovariotomy you cannot compare any results at all with the results obtained or supposed to be obtained by the treatment of a disease like hydrophobia?—Oh no. I do not see how you can talk of them in the same breath or the same week.

15048. Returning to the effects of bacteriology on surgery, I do not think your contention has been made quite clear. Your contention is that bacteriological views rather led surgeons astray in the first instance?—Undoubtedly. If the bacteriologists claim that the study of bacteriology has had any influence upon surgery, then I say that that influence has been a gigantic mistake in the form of Listerism.

15049. Was the term Listerism applied to what is known as antiseptic surgery?—The name was given to the method almost immediately after its introduction.

15050. And am I right in defining antiseptic surgery in this way, that antiseptics, carbolic acid say, were used as a spray to prevent the wounds becoming infected by the microbes contained in the air, and that antiseptics were also used for instruments, dressings, and ligatures? Was that antiseptic surgery?—That was antiseptic surgery as we understood it when Lord Lister invented it.

15051. And it was discarded eventually, just because the use of the antiseptics which were supposed to kill the bacteria injured the wounded tissues of the body?—Undoubtedly that was the sole reason why it was discontinued.

15052. And nowadays, of course, the spray is never used, nor are antiseptics?—No.

15053. And you, Sir William Savory, Mr. Lawson Tait, and others, from your own painful experience by trying this antiseptic method, revolted against what is called Listerism?—Quite so, and I might instance the late Dr. Thomas Keith, who never improved his statistics by one iota after he had adopted the Listerian method; and the result upon himself was that after a long operation under the spray he invariably got an attack of hæmaturia, and he ultimately died from kidney disease.

15054. But Listerism, or antiseptic surgery as I should call it, was advocated most strongly at the time by leading surgeons of the day?—All over the world.

15055. I may quote this passage from your pamphlet giving an extract from an address by the late Sir William MacCormac—he was then Mr. MacCormac: "The lecturer said, 'other methods I would term inexact. The Listerian method is, in contradistinction, an exact method'"?—That is so.

15056. That is in using the spray, and so on?—Yes.

15057. "'Founded on a special theory, and carried out in all its details, in almost precisely the same manner in each case: that the access of ordinary air is very generally the cause of inflammatory or putrefactive changes in wounds," and so forth"?—Yes.

15058. Those were the words used by Sir William MacCormac?—Yes.

15059. So that the consensus of opinion, as it is called, in those days was that the spray must be used for successful surgical operations?—Quite so.

15060. And then, afterwards, the system which was introduced by Mr. Lawson Tait, yourself, Sir William Savory, and others, known as clean surgery, came to be generally adopted?—I may say that the only two operators were Mr. Lawson Tait and myself. Sir William Savory had delivered a lecture at Cork upon the subject, but I do not know how far he carried out his views in practice.

15061. And on account of your strong protest you were blackballed because you referred to it?—That was after I strongly opposed the Listerian method, and advocated the practice of cleanliness; but I did not use the word aseptic.

15062. (*Chairman.*) I daresay it was so, but it would be very difficult for anybody who has been blackballed to say precisely why it was?—I know, my Lord.

15063. I have no doubt that it was an operating cause?—Yes, there is no mistake about it.

15064. (*Dr. Wilson.*) And you define aseptic surgery simply as clean surgery?—Clean surgery.

15065. (*Chairman.*) I should like to ask you a further question. I understood you to say that if you could imagine yourself converted, or perverted, you would say, to the opinion of those bacteriologists who believe and have satisfied themselves that a bacillus is the cause of a certain number of ascertained diseases, then you would think that the pursuit of bacilli for the purpose of discovering and identifying them as the cause of disease by means of experiments on animals would be quite justifiable if you can imagine yourself of their opinion as regards the cause of disease?—I should like to answer that by saying that at present I cannot conceive of my conversion to the doctrine.

15066. But might I assure you that you are not committing yourself to any admission by saying that, but simply putting yourself in the position of agreeing with probably nineteen-twentieths of the experimental physiologists of this country: if you could imagine yourself reduced to that, what would you say?—If I could imagine myself; but I cannot.

15067. Then I will put the question in another way, though I should have thought that you might with ease have allowed your mind to be sufficiently elastic as to follow me; but as you cannot do that, take the case of those who do strongly believe it, do you see any reason why they, holding that opinion, should not endeavour to follow out that line of discovery by experiments on animals?—I see no reason. I see no objection, and I see no reason to object to that.

15068. And also in the same way in the discovery of

remedies by those means—holding those opinions?—Quite so.

15069. Whether these diseases are caused by a bacillus or by a fluid is a thing which cannot be proved either way, you say. Supposing that by experiments on animals you could prove that it was not the fluid but the bacillus, or that it was the fluid and not the bacillus, would you think that experiments for the purpose of ascertaining that very important matter and making it perfectly clear, justifiable?—I should have no objection to experiments of that kind, but I do not think that they ought to be continued indefinitely.

15070. I will not ask you to repeat the conditions that you applied; you applied those conditions that you mentioned before?—Yes.

15071. You said that ridicule was the only answer to be given to those who thought that the plague was produced by the rat flea, and you gave us a reason for that that one witness had said that the doctors who were engaged in examining into the plague question in India wore top-boots to prevent their being bitten by the fleas?—Yes.

15072. That is not all that Dr. Martin, the witness in question, said. His answer is at No. 12111. He is asked, "Incidentally if the rat flea is the ordinary way of communicating the disease, how is it that doctors continually handling these animals in transferring the fleas from one to another, were not bitten?" His answer is "I imagine they were occasionally bitten." And then he added, "For one thing, they wore top-boots," but he goes on to speak of other precautions. I do not know whether you have read the evidence?—Yes, I have.

15073. I suppose that if these fleas do convey the plague it is very desirable not to be bitten by them?—Undoubtedly.

15074. And if there are fleas frequenting rats upon earth floors in a house in India, would you not think it was a very prudent thing to avoid contact with the fleas hopping about; would you not protect your legs?—Well, they will not convey the disease.

15075. But supposing you believed that the rat flea did convey it, would you think that it was a ridiculous thing, if you were going in the course of your duty into a place where you knew there had been plague and where you thought rat fleas were likely to be, instead of putting on a pair of light shoes to put on a pair of top boots?—I should think the protection very insufficient.

15076. It is better than shoes, is it not?—I do not know. The fleas would not attack you on the legs only.

15077. Of course they might fall off the ceiling, but they would be more likely to be on the dusty floor, would they not?—Yes, but I do not accept the doctrine that plague is due to rats.

15078. I know you do not, but you said that one of the reasons why you thought that ridicule was the only answer to that suggestion was that these doctors wore top boots when they went into places where the floors were likely to be frequented with fleas. That is not a very formidable reason, is it?—No, but I probably had other reasons in my mind when I reduced it to two lines.

15079. Dr. Martin goes on to say, you know, that other precautions were taken when they were likely to come in contact with the fleas.

15080. (*Sir William Church.*) The name of an old colleague of mine has been mentioned frequently to-day, Sir William Savory. Of course, he did not accept Listerism in full at first, but are you aware what Sir William Savory's views were with regard to, if I may so call it, the germ theory and suppuration?—I had no communication with Sir William Savory, except some little time after I was black-balled by the society.

15081. Do you know anything more of his views than what you have gathered from the lecture he read in Cork?—No more, except in conversation with him.

15082. And were you in the habit of conversing frequently with him afterwards?—Not frequently, occasionally.

15083. (*Sir John McFadyean.*) If I may ask you one more question, do I rightly understand you to contend that the term Listerism or antiseptic surgery, as introduced by Lord Lister, should be held to cover only the use of the spray intended to destroy atmospheric germs?—And all the other arrangements that he devised.

15084. Do you admit that he also was largely instrumental in introducing methods directed to destroying what he supposed to be the germs on instruments?—That is part of the system.

15085. I think that any person would have gathered from some of the answers which you gave to Dr. Wilson that the aseptic surgery which is now practised universally in London and all over the civilised world is practically what you call clean surgery and claim to have introduced rather than what Lord Lister introduced?—Undoubtedly.

15086. At what period did you begin to apply antiseptics to your instruments?—When I began to practise.

15087. What was the antiseptic that you employed?—Carbolic acid.

15088. Have you given up the use of things intended to destroy the *materies morbi* on instruments?—Absolutely, for the last quarter of a century.

15089. But you do not wish the Commission to believe that that is the sort of surgery that is practised in the London hospitals?—I do not know what the practice is.

15090. (*Chairman.*) I asked you to describe exactly how operations were performed when antiseptics were in vogue and then when the aseptic treatment came in, and you described to me that in the first case first of all the spray was used, which has been abandoned since, and that the hands of the operator were washed with some antiseptic, and that then antiseptics were used, some of them of an irritating kind like carbolic acid, upon the wounds in dressing. I asked you then to describe what was the aseptic treatment, and you said that it was the same, with the exception that the spray was discontinued and also the bringing of anything like irritant antiseptic such as carbolic acid into contact with the tissues; but that with that exception the proceedings were the same as heretofore?—That is so. The distinction between the two is as plain as a pikestaff.

15091. But it is rather different from merely saying soap and water.

15092. (*Sir John McFadyean.*) You really do not want us to believe that in the great hospitals of London at the present time anything approaching your system of clean surgery is practised?—I never contended that.

15093. They would not be content with washing their instruments and their hands with soap and water?—I never contended anything of the kind.

15094. Is that a part of Listerism?—It is not a part.

15095. You say that you began to direct your attention to instruments when you began Listerism?—Yes.

15096. Surely that is a part of Listerism. If not, I am asking who deserves the credit of having introduced it?—Allow me to say that many eminent surgeons do not use any antiseptics in connection with operations at all; that is to say, they keep their instruments in water which they call sterilised.

15097. Hot water, you mean—boiling water?—Just so, water that has been boiled.

15098. Do you want to deny the use of the adjective "aseptic" or "antiseptic" to boiling water?—I say that the use of the term "aseptic" is nonsense, because you cannot say that you have performed an aseptic operation. You can say that you have performed an antiseptic operation, but you cannot say that you have performed an aseptic operation, because you have to wait for the result.

THIRTY-FOURTH DAY.

Tuesday, 12th November 1907.

PRESENT:

The Right Honourable the Viscount SELBY (*Chairman*).

Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir J. McFADYEAN, M.B.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. A. J. RAM, K.C.
Mr. W. H. GASKELL, M.D., F.R.S.
Capt. C. BIGHAM, C.M.G. (*Secretary*).

Mr. J. N. LANGLEY, M.A., D.Sc., F.R.S., called in; and Examined.

Mr. J. N. Langley, M.A., D.Sc., F.R.S.
12 Nov. 1907.

15099. (*Chairman.*) You are Professor of Physiology in the University of Cambridge?—Yes.

15100. And in that capacity you have both to experiment on animals, I presume, and also to teach with regard to experiments on animals?—Yes.

15101. And do you give demonstrations before students?—I generally give three or four in illustration of my lectures in the course of the year.

15102. You have given us the heads of the points on which you desire to speak. I believe first you desire to say something about your personal experience that experiments on animals under the existing Act rarely cause pain?—On that point I wish to state the evidence which has come before me; it is almost entirely in connection with the University of Cambridge. In such a matter it seems to me better to give one's personal experience. I have had experience of the physiological laboratory in Cambridge ever since it was founded, and in that time all the experiments within my knowledge have been performed under the influence of anæsthetics. There are two classes of experiments which are carried out; the first are those simply under a licence in which anæsthesia is always maintained throughout the whole of the experiment and the animal is killed. In those I do not see how, short of gross carelessness, there can be any pain inflicted; and such carelessness, in my experience, does not occur. The other class of experiments come under a certificate; an anæsthetic is given, and then the animal is allowed to recover from the anæsthetics; the pain inflicted is that which occurs in a surgical operation, the experiment is done under the aseptic treatment, and it is done, moreover, on an animal that is healthy. An animal that is healthy recovers from an ordinary skin wound or a surgical operation with extraordinary rapidity. I myself have seen animals in an hour or two after the skin has been sewn up take their food in the ordinary way, walk about perfectly content; cats will purr. What I would call the more ordinary physiological experiment which comes under this certificate really does not inflict anything that can be called pain.

15103. What do you call the more ordinary physiological experiments?—Those are the more frequent ones.

15104. You mean that they may be severe?—Those that are severe I should put under the second class, which I would now speak of. In some of those experiments, possibly—such, for example, as where there is a section of the spinal cord, undoubtedly there is some pain during the process of recovery. That pain is less, I think, than in a human being, but it does occur and is of the same nature as in man. So that what I mean with regard to the class made under the certificate is in the first place that the great majority are quickly recovered from and do not inflict pain, although they come under this certificate which implies that they do. Then, secondly, there are some operations which do inflict pain, but the pain in that case is never, I think, as great as is common in a surgical operation on man. And on the whole, so far as my experience has gone in the Physiological Laboratory at Cambridge, the total amount of pain that has been inflicted is exceedingly slight. There are very few cases where I could have said that the animal had been suffering pain after any operation where the anæsthesia under the certificate has been allowed to cease. I may also mention that during the whole surgical part of the operation the anæsthesia is strictly maintained, that there is no question about doing anything at all on the animal unless it is anæsthetised, and properly anæsthetised. All the skin stitches, for example, are inserted under anæsthesia; nothing is done to an animal except in that condition; then it is put aside and slowly recovers from the anæsthetic.

15105. Do you make any distinction as regards the keeping up of the anæsthesia, where the animal is going to be allowed to come to after the operation finally, between the treatment of an animal and of a man?—None.

15106. You would keep the anæsthesia on just as completely and as long in the case of an animal as you would in the case of a man?—Absolutely.

15107. Does that include the sewing up of the wound and the dressing? In the case of a patient, I suppose you would put them comfortably up in their beds before allowing them to come to?—Yes.

15108. Is that the same process, leaving out that last element?—Yes, entirely the same. Everything that is done to the animal is done under anæsthetics. It is then put aside, and after everything is over it slowly recovers from the anæsthetic. In fact, generally myself I have given a little morphia or a little chloral, or something to prevent it from coming to until some time after the operation, because an animal

will stand more anæsthetic than a man; if it dies there is not the same serious mischief done, of course; so that on the whole one really gives more and prolongs the anæsthetic more in an animal than one does in man.

15109. You say that is your experience in your laboratory?—That is my experience in my laboratory in Cambridge.

15110. But you have studied elsewhere also?—I did work in Heidelberg for about three months, but there were not many experiments going on there at the time, and that is, of course, outside the operation of this Act.

15111. I was going to ask you whether your experience extended in that sort of operation outside Cambridge?—I have seen them in various laboratories outside Cambridge, and they have all been conducted, so far as I have seen, in exactly the same kind of way.

15112. (*Sir Mackenzie Chalmers.*) Just to clear up one point, it has been suggested to us that under Certificate B, it is a frequent course simply to administer the anæsthetic for the purpose of a cutting operation only, and that other exploiting and the painful sequelæ of the operation immediately connected with it are done after the animal recovers. Have you ever known a case of that sort?—It has never even occurred to me. The thing seems to me so foreign from anything that I can imagine is likely to occur in the laboratory that I hardly know how to answer the suggestion.

15113. It would not occur to you to construe that Certificate B as allowing that?—Certainly not; it never occurred to my mind that it could be done. Then with regard to the anæsthetics that are used, no one, I suppose, has any doubt that nearly all the anæsthetics which are used are sufficient to maintain anæsthesia practically indefinitely. I should think that could be taken now as an established fact.

15114. (*Chairman.*) Although it may be taken, amongst scientific men, as an established fact, there are other people who do not understand it to be so. You say that for an indefinite time the anæsthesia may be prolonged. In a case where you are going to give an ultimately lethal dose, but intend to operate in the meantime on the living animal, how long a time can intervene between the giving of the dose which produces anæsthesia and the death of the animal?—Of course, one has never carried on an experiment in that way. All that one can say is that one has never seen any sign of a tendency to recovery of consciousness in consequence of lapse of time; but generally it is the other way, that the anæsthesia becomes deeper and deeper, and the animal more and more immobile the longer the anæsthesia is kept up, and I have seen for something between eight and ten hours' complete anæsthesia maintained.

15115. (*Sir Mackenzie Chalmers.*) With or without artificial respiration?—Without artificial respiration.

15116. (*Chairman.*) So that if you required two, three, or four hours for an operation on an animal, and it was intended it should never come out of the anæsthesia, would you have any difficulty in keeping it under anæsthesia, yet still alive for the period?—Absolutely none—that is quite certain.

15117. (*Mr. Ram.*) When you said the animal would become more and more immobile, did you mean more and more incapable of reflex action?—Yes.

15118. Never at any time capable of conscious action?—Never at any time.

15119. (*Chairman.*) You were speaking about anæsthetics?—Of morphia I have very little personal experience. I have not done many experiments under morphia, but in those which I have done I am quite confident that no pain was inflicted. The animal in those cases lay perfectly still; when severe things like cutting the skin were performed, they did not cause any movement. I purposely tried this in consequence of a doubt which has been thrown out with regard to the anæsthetic properties of morphia. This was an animal that was not fastened, so that there could be no question that if it wanted to get up and run away it could do so; and there was no movement. As I say, I have not done many of those experiments, so that I have not great experimental experience in the use of morphia, but within my personal experience I am confident that pain was not inflicted by the operations of cutting the skin, or by the operations of cutting a nerve which would, without the morphia, have caused very considerable pain. Another point that I should wish to call special attention to is this question of the difference between reflex actions and ordinary voluntary conscious actions. It is, of course, known in man that during anæsthesia in the absence of pain and absence of consciousness movements may occur. I suppose that I need not enter into that; it does not come specially within my province; but, of course, one can say something about it on general grounds if it is considered desirable. But I should take it that it would be accepted that the experience of anæsthetists has shown that there is a degree of anæsthesia which allows movements in man to occur which are not accompanied by consciousness.

Mr. J. N. Langley, M.A., D.Sc., F.R.S.

12 Nov. 1907.

15120. Or by pain?—Or by pain. What I wish to point out is that in animals this limit of range between the disappearance of pain and the disappearance of reflex action is far wider than in man. That is partly, mainly I suppose, because in man the forepart of the brain, which is concerned with consciousness and with pain, is so much more developed relatively to the rest of the nervous system. The rest of the nervous system is really a mechanism for carrying out a number of movements that is controlled by the fore-brain, which is concerned with pain and with consciousness. Now, the greater the normal working of the forepart of the brain, the less is the automatic, the intrinsic, power of the lower part of working by itself. In a very low vertebrate as the frog, all the mechanism of movement is carried out by the spinal cord and lower centres—it can be carried out purely by reflexes. The more the higher centres of the brain, which we may call those of the fore-brain, are developed, the more the lower centres cease to act of themselves. So that a suppression of the higher leads to a greater suppression of the lower. Or, in other words, when in man you suppress the activity of the forepart of the brain, then there is a greater diminution in the ordinary power of activity of the lower parts; they go so far hand in hand. The lower you go in the scale, the less effect is produced by suppressing the higher parts, those concerned with pain and with consciousness. Now anæsthetics are substances which have a special action upon the fore-brain. That is really what is meant by an anæsthetic; it is a chemical substance which acts primarily upon a particular portion of the central nervous system, which is that of the fore-brain. Anæsthetics amongst themselves differ very greatly as to their power of acting upon the lower centres. Chloroform, as I have mentioned, first abolishes pain; then it abolishes consciousness; after that there is a rather narrow limit of increase of dose at which it begins to act upon the lower centres, but for some time after nearly all the ordinary reflex actions have gone, respiration, which is part of the mechanical apparatus, which is part of the working of these lower centres, still goes on. And, moreover, it can be influenced by decreasing the amount of oxygen in the blood; it can be influenced by various effects upon the nerves, so that the mechanism is obviously working in the respiratory centres just as it also works, but to a less degree, in the whole of those lower centres of the spinal cord. The danger of chloroform is in the narrow limit between its acting on the higher and on the lower centres. If you give a little too much, it not only destroys pain and consciousness, but it stops the action of the rest of the brain and of the lower centres. If you give a little too much, it stops respiration; and remember in man respiration lasts a little longer than most of the other reflex mechanisms. Morphia is immensely more selective. Morphia picks out the pain centre, and it leaves these other lower mechanisms for a time practically intact. Moreover, it not only does that, but it stimulates a certain part of these lower centres, quite special ones, and they are those which do not give rise to pain in normal life. In an animal under morphia this selective action can be shown (it is obvious) in this kind of way. If a small point of the skin is taken between the fingers and pinched hard, nothing results; if a knife is taken and the skin is cut there is no movement; but if you give a loud rap on the table close to it, causing vibration, then there will be a more or less convulsive start of the whole animal. That is not a painful sensation.

15121. That is caused by the action upon the animal's nerves?—Yes, it is caused by the action on its lower mechanism. The evidence that is really produced by the mechanism is that as you increase the

Mr. J. N. Langley, M.A., D.Sc. F.R.S.

12 Nov. 1907.

morphia the special reflex to a certain extent increases, and it continues (when it is pronounced) after the whole of the fore-brain has been removed. It would continue in a portion, in the hind limbs for example, after not only the fore-brain, but the whole brain, and the top part of the spinal cord, had been removed, so that there is little more (in that case, of course, artificial respiration must be kept up) than a fragment of the nervous system with the hind limbs depending from it. In that state, if you gave a sharp rap causing vibration, the hind limbs start in exactly the same kind of way that the fore-limbs and body do in the intact animal under morphia.

15122. Is that an experiment that would produce the same results in man as it would in any animal?—I believe that you would get the same sort of thing in man if the observations were made in the same conditions. In man many people have described the convulsive action which occurs near the point of death with large doses of morphia. It is well known, in fact, that there are certain twitchings of the muscles, and that these ,in certain particular cases, spread into real convulsions with excess of morphia. It is in a state of deep coma that this occurs. In fact, not uncommonly death results from the convulsions which are produced in coma. The convulsions are, I am certain, the same kind of thing as this increased reflex that is produced in the lower animals. In man, what is done to keep a man alive when an excess of morphia is given is to take him and shake him. He is walked up and down the room. It is old fashioned ; it is not done as much now, but it was an empirical experiment, that to save a man from morphia you marched him up and down, shaking him at intervals and shouting at him. So far as any painful stimulus was concerned, he was in a state of profound stupor, and took no notice ; but the shaking produced some kind of evidence that all this lower reflex mechanism was still reacting. I am quoting this not so much on the action of morphia itself as an anæsthetic, as in relation to the degree of movement that can be obtained after complete loss of consciousness. What I want to insist upon is that each anæsthetic has special properties, that the nervous system consists of groups of nervous centres performing different functions. Anæsthetics form an incoherent group of chemical bodies which have this in common, that they act first on the central nervous system in the part where pain and consciousness lie ; after that there are endless differences in the other effects ; they may, like chloroform, rapidly sweep through all the rest of the central nervous system and destroy the function of that too ; they may, like morphia, linger in the higher nervous system and only slowly proceed to abolish the lower. Further movements which are reflex, and which may be produced in anæsthesia, are the movements which are produced by a diminution in the amount of air, or a diminution in the amount of oxygen. In animals in a state of deep anæsthesia, if asphyxia is produced ; that is, if the supply of air is cut off, you may get more or less struggling movements which diminish with the depth of anæsthesia, but in perfectly complete anæsthesia it will cause rather strong movements ; the reflex action upon this respiratory mechanism is seen though to very much less extent in man also. The evidence that in animals it is reflex is shown by removing the obstruction. Almost immediately the air gets into the lungs and the blood gets oxygenated, the movements cease and the animal is perfectly quiescent.

15123. Is it the case also that the animal has become insensible?—Absolutely insensible. The anæsthetic is given first ; it is given to a stage in which the animal could be tossed about without any indication of movement. Then the trachea is stopped, the breathing is stopped by stopping the inlet of air, and movements will begin. The air is allowed once more to get to the lungs, and the movements stop. The trachea is stopped, once more, *i.e.*, the supply of air is cut off, and the movements begin again, and so on ; it will go on in this state of anæsthesia constantly with the regularity of the ticking of a clock.

15124. In ordinary suffocation not arising from anæsthetics, does a man become unconscious before he dies?—Yes.

15125. There is a space?—Yes.

15126. In that space does he struggle?—He struggles early, and for some time after unconsciousness is produced ; unconsciousness comes on rather early in suffocation, so far as can be judged by external appearance in man and by what is said by those who recover, but the movements in suffocation go on practically up to death, and usually there are rather slow laboured respirations at long intervals at a time when consciousness must have long gone. It varies greatly in different individuals. In the case of an animal that is anæsthetised, and then is asphyxiated, there is a regular series of ways in which the nervous mechanism works, and the last are inspiratory gasps which occur at an interval of perhaps 10 or 20 seconds, long drawn, and then they diminish and slowly die out. During that time and long before that the animal is completely unconscious. I have mentioned above methods in which various movements are obtained in anæsthetised animals, and which in the description of experiments in physiological accounts give rise to great misconception. There are many people who think that when in the account of an experiment it is said that the animal moved, or that the animal struggled, it implies a return to consciousness. That is not the case. It is perfectly certain that all the varied kinds of reflex movements and the general movements of the body may be noticed long after all pain and consciousness have gone. As a last example a small reflex movement may be produced by slight tension of the limbs, sometimes when the feet of an animal are fastened there may be a rhythmic movement of the hind limbs.

15127. You mean while the animal is under anæsthesia, but fastened, to counteract any movement?—To steady it and prevent it from rolling over.

15128. In order to prevent reflex movement?—Yes. merely to steady it. If the cords are relaxed to a certain extent the movements stop. If you gently tighten them the movements begin. If you relax them again they stop, and so on. It is the effect of slight tension ; moreover, that occurs with a portion of the spinal cord only, without any brain and without any medulla in the animal, in which practically everything has been removed, and I have not the faintest doubt that that would occur with artificial circulation ; if you could remove all the front part of an animal, and take only the posterior part, and inject arterial blood through it, you would get the same regular movements steadily occurring on a particular kind of tension.

15129. That, I think, is what you wish to say about anæsthetics?—Yes.

15130. You, of course, have formed some opinion as to the value and importance or the reverse of using experiments on animals for the purposes of physiological and medical knowledge?—On general grounds it seems to be almost self-evident that as physiology is the study of the mode of action of the living organism and of its various parts, that they must be studied living, because the function ceases when life ceases. Anatomy, the use of the microscope, observations in health and disease, offer suggestions as to functions, but these must necessarily be tested by experiments, for otherwise they leave room for endless conjectures. To take a single example. The functions of certain nerves can only be determined by actual experiments on animals. It is impossible to discover where a vaso constrictor or a vaso dilator nerve runs except by trying it. There is no microscopical difference, there is no anatomical difference. The only way of noting the difference between a vaso dilator and a vaso constrictor nerve is to try and stimulate the nerve and see what effect is produced.

15131. (*Sir Mackenzie Chalmers.*) That is not necessarily a sensitive nerve?—No, a peripheral nerve, a nerve removed from the centre and running to the periphery of the organism, as to a muscle or gland, will serve for experiment.

15132. Is that necessarily a sensitive nerve?—Not necessarily.

15133. (*Chairman.*) In point of fact, was the distinction between those nerves known before experiments on animals?—It was not known before experiments on animals, I think.

15134. Was it known that there were two sets of nerves, apparently the same, but having different functions or action?—So far as I know it was not known. I have not discovered any reference to it before the experiments of Claude Bernard.

15135. It is now known by those means, I under-

Mr. J. N. Langley, M.A., D.Sc., F.R.S.

12 Nov. 1907.

stand, that there is that distinction, and you can discover which nerves act in a particular manner?—You can discover which nerves cause dilation of vessels, and which cause them to contract. And in the same way nearly all we really know of the functions of the different parts of the body has been derived from experiments on living tissues and living organs and living animals. With regard to the applicability of the results obtained on anæsthetised animals to unanæsthetised animals, it has been said that observation made on animals under anæsthesia are not applicable to ordinary life, because they are abnormal. The use of the word abnormal in that sense is purely misleading; it depends on a juggle with words. It seems to be supposed that anything that can by any chance be labelled abnormal must therefore be inapplicable to normal life. It is obvious that that is not the case, because one of the ordinary meanings of the word "normal" is "average."

15136. I do not understand why the words normal and abnormal are used. The question is rather, is it not, whether you cannot necessarily apply to human life a conclusion which you may safely draw from animal life? You would not say that if the life of an animal, or its construction, differed in some respect from that of man, it was abnormal?—No, I take it that one objection that has been made to experiments is that the anæsthesia modified so much the whole character of the living tissue, that you could not apply the results to the normal unanæsthetised animal.

15137. I see. I thought you were arguing simply from animal to man?—No, the relation of animal to man is, I think, the second line of argument; but the first, which is more general, is that you cannot use any result obtained under anæsthesia. Of course, that depends upon a purely verbal juggle with words. The abnormality consists solely in the alteration in pain and consciousness. As I have indicated, the nature of anæsthetics is, to begin with affecting certain parts of the nervous system, and it is only subsequently that they go to other parts of the nervous system, and it is subsequent to that that they proceed to the muscles and nerves and the various glands in the various parts of the body. So that, in fact, nearly all the parts of the body are normal, and in the ordinary condition; their state is one which allows conclusions to be drawn as to the condition in ordinary life, except as regards the particular circumstances of pain and consciousness. The animal is abnormal. The tissues are not abnormal; they are perfectly normal. So that in that way all the muscles, the blood vessels, and viscera—nearly the whole body except just this part of the brain connected with pain and consciousness—is in a condition which allows you to definitely state what is the condition in ordinary life. With regard to the applicability, then, of experiments on animals to man, it is to be noted that the tissues of man and the organs resemble very nearly those of all other vertebrate animals, so that there is a probability that the function of any one tissue or organ in any one vertebrate would be approximately the same as that which it has in other vertebrates. Further, if you find a function in a number of different animals, the probability, then, is very great that there will be a similar function in man, and the more animals that you can show have the same kind of function, the more it is necessarily applicable to man. As a matter of fact, a similarity, and often a very close similarity, has been shown over the whole range of physiology to exist between man and the vertebrates. The normal working of the parts of the human body differs in most cases only in detail from that of the higher mammals, so that experiments on animals give to a large extent positive evidence with regard to the condition of man. But they do more than that, because they clear away a number of erroneous hypotheses. If we look back to the history of medicine, it is clear that treatment is always open to a number of erroneous modifications, until a definite reason is given why a particular method of treatment should be applied. As soon as a reason can be given, then a particular line of treatment is rapidly adopted. It satisfies the human mind to have something which it can positively say is the cause of a particular thing. Until that can be given, so long there is room for numerous conjectures, numerous side issues, and numerous different forms of treatment. That is really indicated at the present day very largely by the different treatments in nutrition. One will recommend the constant feeding on meats; another constant feeding on this or that diet. These different treatments which are considered to be useful in particular functional processes mark the fact that we do not know the scientific reason for the dietetic methods, and, in consequence, all the possibilities of treatment are open and have followers; so that the greater the number of possible ways of accounting for a fact, the greater is the number of erroneous methods of treatment. Physiology, I think, then, aids medicine and surgery in those two ways, in that it brings positive results which are in the highest degree probable for man, and then that it clears away a number of erroneous hypotheses, and gives some firm ground for explaining current practice, and so leads to the adoption of the practice which is really the best and the most useful for the purpose.

15138. Are experiments upon animals, in your opinion, necessary in order to correct a great many errors which arise from hypothesis or suggestions?—I think they are absolutely necessary. The usual method is to disprove first one hypothesis, and then to disprove another, and gradually to arrive at truth in that way, but each step in the process, I think, is valuable in its application to the ordinary treatment of medicine and surgery.

15139. Of practical value?—Yes, of practical value. One case of a particular advance in surgery which I should like to bring before the Commission is that of the effect on the surgical treatment of diseases of nerves and of severed nerves, which has been brought about by experiments on animals.

15140. Do you mean so as to enable you to know how you should treat a case of an accidentally severed nerve in a man?—Yes. I think that has come from experiments on animals. The earlier relation I may treat quite briefly. Animal experiments disproved the old medical and surgical belief which came from Galen that nerves could not be healed at all. That was current till about 1770, and then Cruikshank and a number of other observers, by experiments on animals, which went on to 1822—they were, in fact, on dogs—showed that nerves could heal when joined together. That was adopted in surgical practice, and it became the custom then to join up the central end with the peripheral end of a severed nerve, and in a very short time it was found that the difficulty in certain cases was not to cause nerves to join, but to prevent their joining too rapidly in particular instances, as, for instance, in neuralgia. A modification of the treatment was introduced in the case where a large portion of a nerve was cut out. That, again, so far as I have been able to discover, was first introduced by Philipeaux and Vulpian in 1869, who in dogs introduced a portion of a foreign nerve between the central end and the peripheral end of the cut nerve, and found that the piece introduced could aid and help regeneration. That also is a constant practice in the surgical treatment of nerves.

15141. Were all those experiments made without anæsthetics?—I should think the earlier ones were made without anæsthetics, but the last that I have mentioned, those of Philipeaux and Vulpian, I think were experiments under anæsthetics. The earlier ones undoubtedly were without anæsthetics.

15142. They would be very painful operations, I presume?—That depends upon the nature of them. The simple connection of a severed nerve I do not think would be necessarily painful.

15143. Some of them, at all events, would be painful operations?—Yes, some of them would be.

15144. (*Sir Mackenzie Chalmers.*) They were foreign experiments?—They were made in France. The earlier experiments of Cruikshank were published in the Transactions of the Royal Society in 1789, I think; they were by an Englishman, in 1770.

15145. Can those operations be done now under anæsthetics?—Yes.

15146. (*Chairman.*) They could not be done then under anæsthetics?—They could not; there were no anæsthetics discovered at that time. The two main points then were, first, the actual union of a nerve after having been severed, and then the introduction of a piece of nerve. A further development then was in joining the central end of one nerve to the peripheral end of a different nerve, which is necessary in certain operations. For example, when a facial nerve is injured in the skull, as it is sometimes by an abscess, or by other causes, such as bullet wounds

Mr. J. N. Langley, M.A., D.Sc., F.R.S.
12 Nov. 1907.

and so on, the central end cannot be got at—it is too deep down and in the bone—for the purpose of joining on to the peripheral end. What is done now, consequently, is to take the central end of another nerve and to join it on to the facial nerve, and that, it is found, produces recovery from facial paralysis more or less complete. This operation is one which can be traced with remarkable closeness immediately to operations which were made on animals. There was first a series of experiments which showed that the thing was possible—that is to say, physiological experiments which were purely of a scientific nature. The first of these was a very early one by Flourens, in 1824-1828, who performed the operation of the cross-union of nerves in the wing of a fowl. He took the nerves which run to the upper portion of the wing, and joined them to those which go to the lower portion, and *vice versa*, and he found that in no long time the fowl could use these nerves, and could fly—that they had actually joined crosswise—that the central end of one nerve had joined on the peripheral end of another and different nerve. Then physiological experiments on other nerves were made by Bidder in 1842, and by Philipeaux and Vulpian in 1863. That then led to some operations in France by Desprès in 1875. Further experiments on animals of a more recent kind are those of Rawa in 1885, Stefani in 1886, Howell and Huber in 1892, Cunningham in 1898, and Kennedy in 1901. All of these joined nerves which were approximately of the same kind. Schiff and Reichert in 1885, and myself in 1898, tried nerves of a different character; those in my case were apparently of a thoroughly different nature, and it was found that there also the central end could join the peripheral end. So that it was an established scientific fact that almost any motor nerve could join the peripheral end of another motor nerve. It took a little time before this purely scientific physiological deduction was translated into actual practice; that was done in France, Germany, America, and England with a few years; in nearly every case the deduction for the operation in facial spasm and facial paralysis in man was made as the result of the experiments mentioned above. Up to about 1898 facial paralysis in man was regarded as incurable, and certain kinds of facial spasm were also regarded as incurable. Nobody thought of doing anything except ameliorating the methods of treatment. Nobody supposed for a moment that they could be healed. The first successful operation was by Kennedy in England. The operation was performed in May, 1899. The paper giving an account of it was read before the Royal Society on November 22nd, 1900, and published in the Philosophical Transactions, 1901. The case was that of a woman who was admitted to the Glasgow Western Infirmary on account of chronic spasms and incessant muscular twitchings on the right side of her face, which had lasted ten years. As a result of that operation, the tonic spasm disappeared, and control over the muscles of the face was regained. Kennedy definitely states that he performed these operations because of the general physiological result that was known, and because of the experiments on animals which he made himself directly for the purpose.

15147. Was that a new operation on man?—Yes.

15148. And was it successful?—Quite successful.

15149. What was the condition of the person before the operation?—In Kennedy's case all one side of the face was in constant twitching, a very uncomfortable thing; there was tonic spasm which gathered up the corner of the mouth across the face.

15150. Was it disfiguring?—Most disfiguring; it would practically prevent the subject entering into a great many of the ordinary occupations of life.

15151. And after the operation did these spasms entirely disappear?—They entirely disappeared.

15152. And the face resumed its normal appearance?—Recovery is rarely absolutely complete; there is generally some sign left. But control over the face and control over the muscles was restored—that is to say, all this drawing of the face and the mouth to the side disappeared.

15153. But there are some traces left of the disfigurement?—I think in all these instances there will be some traces left. But Kennedy said that what induced him to try the experiment—which was, of course, rather a daring thing to do on man—was this: "Being convinced that voluntary co-ordinated movements had been restored after nerve-crossing in the dog, I decided to treat the case by dividing the facial nerve and grafting its peripheral segment on to the spinal accessory nerve, in the hope that the same result of nerve-crossing would result in man as had proved to take place in the dog."

15154. You have in print before you, I believe, the remaining evidence of the success of these operations?—I have. Subsequently several cases of facial paralysis, treated by joining the spinal accessory nerve with the peripheral end of the facial were described by C. A. Ballance, H. Ballance, and Purves Stewart ("British Medical Journal," May 2nd, 1903). In this paper Mr. C. A. Ballance mentions that he first performed the operation in 1895. The result was not known for some years, as the patient was lost sight of. Mr. Ballance informs me that he felt justified in making the operation "by the fact that the cross-union of nerves had long been known by physiologists to be a successful operation." In France the first operation for facial paralysis was performed by Faure [Faure and Furet, "Gazette des Hôpitaux," 71 An., 8 Mars., p. 259, 1898]. Furet suggested to him [cp. Bréavoine (op. cit. infra)] that the hypoglossal nerve should be joined to the facial. The choice of the hypoglossal may reasonably be attributed to this nerve having been used in the well-known experiments on the cross-union of nerves by the French observers Philipeaux and Vulpian.* On discussing the question, they came to the conclusion that the spinal accessory would probably be a better nerve to take than the hypoglossal. The operation was performed early in 1898. Nine months later Faure ["Revue de Chirurgie," T 18, p. 1098, 1898. Improvement in this case was noted at a later date, and in 1901 (Congès de Chirurgie, Paris, 1901) Faure describes it as a partial success] reported that no recovery had taken place. He argued, however, that success would be obtainable in proper conditions, since it had been shown that different nerves of the same nature can become functionally connected. The failure of the operation could not, however, but raise some doubt as to its feasibility, and this led Barrago-Ciarella [Barrago-Ciarella, "Il Polichnico," 1901: "Per consiglio del mio maestro, che vivamente ringrazio, ho voluto tentare la risoluzione del quesito che Furet e Faure vollero sciogliere, limitando pero questa mia prima ricerca al fatto, se cioè nella procurata paralisi facciali mediante la sezione del nervo alla sua uscita dal forame stilomastoides con l'immediata sutura del moncone periferico di questo all'estremita centrale dell'accessorio, resecata al momento del suo ingresso nella faccia interna dello sterno-cleido-mastoides, sia possibile ripristinare la perduta funzione dei muscoli innervati dal 70"] to test in dogs how far return of function could be brought about when the spinal accessory or the vagus was joined to the peripheral end of the facial nerve by primary suture. He made three experiments on dogs, and found that recovery of motor power occurred in each case. At Faure's suggestion, Bréavoine [Bréavoine, "Travaux de Neurologie Chirurgicale," Vlme. An., p. 92, 1902] in 1901 drew up a statement of the observations made in various countries up to that date: "Dans le but de faire connâitre en France les heureux resultats de cette opération, tant sur les animaux que sur l'homme." In America the first operation was performed by Cushing [Cushing, "Annals of Surgery," May, 1903] in May, 1902. The patient was a man of thirty years of age, in whom the facial nerve had been severed by a bullet wound. "Motor paralysis was complete on the right side of the face and in the platysma as well." "Bell's sign, the rolling of the eyeball on attempted closure of the eye, inability to pronounce distinctly the labials, lacrymation, and the other many discomforts attending on the condition of facial palsy, were present." As a result of the operation the discomforts disappeared, the muscles were saved from atrophy, and voluntary control over them regained. The operation was suggested to Dr. Cushing by experiments made upon cats. He says (p. 4) the "suggestion for such an operation came to the writer through cognizance with Langley's experimental work on the transference of nerve function after anastomosis between the vagus and the sympathetic." Other similar operations have recently been made by Korte in Germany, by Dr. Tubby in England, and probably by others elsewhere. It may

* *Faure and Furet refer to Lebierant, who refer to Philipeaux and Vulpian.*

safely be predicted that the operation will alleviate human suffering and distress all over the world. But there are several questions still to be settled before it can be definitely ascertained what is the best method of operation. Thus it is probable that if the whole spinal accessory were cut through, the central end of the trapezial branch joined to the facial, and the remaining central branch joined to all peripheral branches of the spinal accessory, the maximum of independent voluntary control would be regained, with litle or no permanent paresis of the muscles supplied by the spinal accessory. The further experiments, if not made on animals, must be made on man. Facial paralysis in an animal is much less distressing than in man, since a large factor in man, the consciousness of a distorted face, is absent in animals. Since I wrote the pamphlet from which this evidence is taken, *i.e.*, last year, my attention has been called to further operations which have been suggested by these operations, so that the effect is accumulating.

15155. Operations on the nerves?—Operations on the nerves in man.

15156. Had these operations ever been attempted before on man?—No. The operations which are now being carried out are those on birth palsy. When a child is taken out by instruments, it sometimes happens unavoidably that the nerves of the brachial plexus or elsewhere are torn, and that leads to permanent paralysis, which is called birth palsy. This has suggested that one of the central ends of a sound nerve of the brachial plexus should be joined on to the peripheral end of a nerve which has been injured; that has been done, and with success; the child has been saved from lifelong paralysis in that way. There is another disease, called acute anterior poliomyelitis. This is a disease of a certain number of cells in the spinal cord, which causes partial paralysis. There again the nerve which has these unsound diseased fibres is joined on to the central end of a portion of a sound nerve and that has also led, so far as it has been carried out, to satisfactory results.

15157. When you speak of the central end of a nerve, what exactly do you mean?—I mean the end that is connected with the spine. Then again in athetosis, which is a continued spasm of certain muscles, the flexor muscles of a limb are sometimes very much stronger than the extensors, and cause various twitchings and tonic spasms. What has been done has been to take the nerve from the flexor side and join it on to the extensor side, so that the excess of action which goes to the flexors is diverted to the extensors, and a balance is fairly maintained. That also, so far, is a success.

15158. How do you regulate the extent of the operation in accordance with the extent of the excess?—That can only be done, a little empirically, by estimating how much stronger the muscles are on one side than on the other, and taking the corresponding portion of a nerve to join across; the one is grafted on the other. A portion of the flexor nerve might be cut out, and the extensor nerve drawn across and joined on to the flexor nerve.

15159. Has that been done?—The operation has been done by Spiller, Frazier, and Van Kaathoven, and the account of it is to be found in the American "Journal of Medical Science," 1906.

15160. Is that of practical benefit to the person who has it done?—It is.

15161. Is the defect from which he was suffering a serious one?—Yes, very serious. These operations are of the very greatest benefit to people on whom they are performed.

15162. It is not a very common operation, is it?—I can hardly say how common they are. At present there are certainly not a great many operations being performed; it is entirely recent.

15163. In your view, are all these operations the consequences of experiments on animals?—I could give you a statement of Dr. Frazier, who wrote the paper in the "American Journal," and who is partly responsible for these operations.

15164. As you have given us the reference it will be enough, I think, if you can say that he does or does not attribute them to experiments on animals?—He attributes them to experiments on animals.

15165. And that will be seen on reference to his paper?—Yes. Lastly, there is the operation for partial hemiplegia, which is allied to these, and which hitherto has been quite intractable to treatment.

15166. Has that been remedied by operations?—In the few experiments which have been made the operation has distinctly benefited the patient.

Mr. J. N. Langley, M.A., D.Sc., F.R.S.

12 Nov. 1907.

15167. It may be said that these operations might probably have been discovered without experiments on animals, although, in fact, the possibility of them was discovered by that means. Does it occur to you that such might have been the case?—It is impossible to say that they might not have been discovered in the next century, but they would not have been discovered in this. One can only judge by seeing the progress of past inquiry, and the progress of past inquiry when it has been confined to man without the co-operation of experiments on animals has been so slow that I think we may legitimately say that without experiments on animals, these things would not have been discovered within any reasonable time.

15168. If they were discovered?—Exactly. It only means that experiments must be made on man or on animals, it is a choice between the two. No doubt, if experiments were made on man the same kind of things could be discovered, because, as I have already indicated, I think that many of the higher mammals are so closely similar, that what is applicable to one is applicable to another.

15169. Have you had any experience of the use of curare?—I have had experience of the use of curare for particular experiments, and having obtained a knowledge of the way to administer anæsthetics, I am confident that there is no difficulty in keeping up the anæsthesia whilst curare is given.

15170. And what seems to be very important, is there any difficulty in the operator knowing that the effect of the anæsthetic is complete throughout the whole time of the operation?—He must start with complete anæsthesia, and he must know from past experience the amount of the anæsthetic which it is necessary to give in order to maintain it.

15171. Must he start with the anæsthetic before he gives the curare?—Yes, before he gives curare the anæsthetic must be given.

15172. And then he must satisfy himself that the animal has arrived at complete anæsthesia?—Yes.

15173. And with a dose that will last for a certain time?—Yes, and which must be repeated. For instance, with chloroform, the chloroform is given at the intervals, and in such doses as his previous experience has shown will maintain complete anæsthesia.

15174. Assuming that he uses adequate care, the care that you have a right to expect from a skilled anæsthetist, would he have any difficulty?—I do not think he would have any.

15175. But he would have to rely on the dose and on his watchfulness?—Yes.

15176. That is to say, he could not see from any signs in the patient anything that would satisfy him?—There is the state of the blood pressure which will indicate, to some extent, the reflexes on the vascular system.

15177. Would pain felt cause an increase of blood pressure?—It would cause a rise of blood pressure, but I should myself always rely on the previous experience of the anæsthesia—how it is produced and the depth of it, and see that it is maintained in just the same way as if the curare were not given.

15178. Is that the precaution you have seen adopted when the curare has been used?—Yes, that is the mode. An anæsthetic is always given in my experience.

15179. Are there any operations on animals to which you can point in which you would say that the use of curare was necessary?—There are two operations which I can mention, which I have myself performed. One is in investigating the origin of the class of nerves called sympathetic nerves, from the spinal cord. These nerves issue from the spinal cord with nerves to the muscles, and in investigating where they originate, the nerve is severed from the spinal cord, and the end which is not connected with it, but connected with the periphery, is stimulated; that is to say, stimulation in a live unanæsthetised animal could not give any pain. That experiment would give extremely uncertain results unless curare were given, because the musclar movement which is caused by the other nerves mixed with the sympathetic nerves obscures the action of the sympathetic nerves themselves. They must be seen by themselves in order

Mr. J. N. Langley, M.A., D.Sc., F.R.S.

12 Nov. 1907.

to be distinctly appreciated—for example, whether they cause constriction of blood vessels. If a muscle is tight and contracted, of course, it causes blanching or squeezing of the blood out of the blood vessels, and so there is a pallor which might be attributed to the sympathetic nerves, but which is really due to the other class of nerves. Then another kind of experiment that I have had occasion to try is that of showing certain nerve fibres going to the sphincter of the stomach, which cause dilation of the sphincter, which cause it to relax instead of causing it to contract. That experiment was done on a rabbit, and in the rabbit there are fibres running to the sphincter which do not belong to the sympathetic system, but which are of the same character as the muscles of the limbs. Those must be put out of action by curare before you can determine whether the sphincter contracts or dilates, or is inhibited when the nerve is stimulated. One could have got no satisfactory proof of the presence of inhibitory fibres in the sphincter of the stomach unless curare had been given. When curare is given the proof is absolutely clear and one or two experiments settle the question.

15180. We have had suggestions made that even if experiments on some animals are permitted they ought not to be permitted on dogs. Have you anything to say on that point?—In all experiments on animals, of course, one would naturally prefer, for various reasons, sentimental reasons, to avoid the use of higher mammalia. The same sentiment which makes one hesitate to experiment at all applies with increasing stress the higher you go in the scale of animals, ending, of course, in man himself; but experiments on dogs I think sometimes are absolutely necessary. Of course, on general grounds it is clear that physiological laws must have a broader basis the more different kinds of animals are investigated, and to remove dogs from the category would be to limit the general application and determination of physiological laws. Professor Starling has already given a number of instances in which dogs are required for experiments, and I need not repeat those. I would only mention two which are of immediate interest to me in my own work. One is in relation to the sympathetic nerve fibres which run to the lips and to the gums. In no other animal can that be properly investigated, since vaso-dilator fibres in this region are much more developed in the dog than in any other animal, and it is necessary, I think, to perform experiments on dogs in order to arrive at any satisfactory result.

15181. With what object?—To find out the general relation of the vaso-dilator nerves in the sympathetic system. It is the only case, as it happens, which is definitely known, which can be shown, in which there are vaso-dilator nerves in the sympathetic system at all; and the following out of that problem may lead to very interesting and very important results. At the present moment, of course, one cannot definitely say what is likely to come from it.

15182. It is research really?—It is research. And the second instance also is a piece of research work of the same kind, that is to say, as to the presence of vaso-dilator fibres in the posterior roots of nerves. These may be of great physiological importance, but there is so little known about them at present that it is almost open even to doubt their existence, and it is certain that the investigation of them, so far as one can see at present, must be performed on dogs, and that no other animal will adequately meet the case.

15183. As regards teaching by means of demonstration experiments on animals, you practice that to a certain extent yourself, and therefore I presume that you approve of it—that you think it necessary?—I approve most strongly of giving a certain number of demonstrations to students. I think they ought to see in the first place an experiment, under anæsthesia, so that they may judge of it themselves, and form a clearer idea of the working of the body. They cannot see it in any other way. It is always recognised that wherever you can show a thing, the fundamental truth of it is much better appreciated if it is seen rather than if it is simply read about, and in my experience the students take the greatest, but a serious interest in the demonstration, and I do not understand at all how anyone who has been familiar with students attending those demonstrations can say that they have any demoralising influence whatever.

15184. Have you seen any symptoms of it at Cambridge?—Absolutely none.

15185. Your classes almost entirely consist, I presume, of those who are either going into physiology as a profession, or are going to practice medicine as a profession?—Yes.

15186. About how many would there be in a class?—About 100.

15187. Would only a certain number of those be present at demonstrations?—They would all be present at demonstrations—*i.e.*, the demonstrations are open to all.

15188. Could they all see the demonstration?—If it is a case where they cannot all see, it has to be repeated in two sections.

15189. (*Sir Mackenzie Chalmers.*) That is to say on two animals?—On two animals.

15190. (*Chairman.*) Have you seen any sign of heartless conduct on the part of students—exhibitions of jesting, I mean?—I think it is quite the reverse; that they are all extremely anxious to assure themselves that the animal which is there has no trace of pain. One of the things which I generally show in a course is some of these reflexes during anæsthesia, because as a rule they are not satisfied on the first view that the movement can be carried out in a wholly anæsthetised animal. They always press home the point, and that is usually shown to them in such a manner that they can satisfactorily convince themselves of it. I am sure that there is no levity of demeanour; that they are extremely impressed with the necessity of avoiding the infliction of any unnecessary pain.

15191. You think that the public opinion of the students would be quite against any exhibition of levity?—Entirely. It would, I think, be impossible.

15192. Have you any suggestions to make with regard to amendment of the present Act?—I have some suggestions to make on the lines that I think that if precautions have been taken to prevent severe and prolonged pain, and to prevent any unnecessary pain, it should be the object of the Act rather to encourage than to discourage experiments on animals. I think in the first place that the interference with research, which is caused by the necessity of taking out certificates in addition to a licence, should be lessened. I would suggest that after a licence has been held for, say, ten years, it should ordinarily be endorsed with permission to make experiments under any of the certificates, a return, of course, being made of such experiments as are performed. In the next place, I am inclined to think that the injection of non-irritating substances under the skin, and feeding experiments when they are not calculated to give pain should be excluded from the Act altogether. I think it creates a good deal of prejudice to see that a large number of experiments are made, many of these which are not experiments of a painful nature at all. That experiments merely involving a prick of the skin should be massed together as experiments requiring the sanction of an Act of Parliament does not seem to me to be a satisfactory thing. Then again, I think the necessity of taking out two certificates for an operation on a cat or dog, that is to say, B and E E, or, in the case of a horse, ass, or mule, B and E E and F, should be got rid of, and that one certificate should be substituted. I should, by the way, add the monkey to the same class as the cat or dog.

15193. (*Sir Mackenzie Chalmers.*) Do you mean that the ordinary Certificate B should include the right to experiment on dogs without a special certificate?—If you want to experiment on a dog, there should be a separate certificate, that you should not have to get Certificate B first. Now one has first to get B and then E E.

15194. (*Chairman.*) You would have Certificates A, B, and E E all on one piece of paper, you mean?—So far as I understand the Act you cannot do an experiment on a dog without having certificate B.

15195. (*Sir Mackenzie Chalmers.*) You might have A and E E?—Yes, but that means two.

15196. You might have A and E E or B and E E?—Yes, but you must have two. If anyone is researching and only wants to do experiments on dogs, why should he get Certificate B, which is for experiments on other animals?

15197. Certificate B covers animals generally which are to be experimented on with anæsthetics, and then are to be allowed to recover?—Yes.

15198. Then, if you want to go into the particular category of dogs you get Certificate E E as well?—Could you not go at once to the category of the dog without the intermediate stage of animals generally?

15199. If you had Certificate E E only, the persons who give the certificate would not know whether you want E E plus A or E E plus B?—The certificate might be headed A plus E E; then you would obtain it direct, instead of getting two sets of signatures and having two certificates to fill up. There are various ways in which it might be done.

15200. (*Chairman.*) You mean that it would save time and trouble in applications?—It would save time and trouble to the people who have to sign. It is rather hard, for instance, to take up the time of the President of the Royal College of Surgeons in giving signatures, if it is unnecessary.

15201. And it would save time in getting the certificate, and not waiting for it?—Yes.

15202. Are there any other alterations that you would suggest?—In the certificate for teaching purposes I think that the word "absolutely" before "absolutely necessary" should be struck out, because it is so much a matter of argument what you can say an experiment is absolutely necessary for. It comes to this, that for teaching purposes at present, only experiments which are absolutely necessary can be performed, and the word "absolutely," I think, throws an unfair onus on the holder of the certificate. If it comes to a court of law he does not know what view will be taken as to the meaning of "absolutely" in that sense. Because from the physiological point of view there is nothing that is absolutely necessary. There are things which are advisable, and there are things which are more or less necessary, but I doubt whether in any scheme of education, short of learning to read and write, you could say that anything is necessary, if it is pressed home to a point.

15203. You prefer something nearer to the word "desirable"?—I think if you say "necessary," and leave out the "absolutely," that would be adequate. People would then understand it; they could say it is necessary to their functions. There are many things which you can say are necessary, but I think there are very few things which you could say are absolutely necessary.

15204. (*Sir Mackenzie Chalmers.*) The Act assumes that certain experiments will be absolutely necessary, or it would not have made that provision?—Yes, it is an alteration in the Act which I am suggesting.

15205. The Act assumes that certain experiments must be absolutely necessary, because it makes those exceptions, and leaves you to determine what they are?—I suggest that that is throwing an unfair burden upon the licensee.

15206. (*Chairman.*) I understand that your view is that the condition should not be that you have to prove the necessity, but the desirability in the interest of science, or some words of that sort?—Yes.

15207. (*Sir Mackenzie Chalmers.*) What word would you substitute?—I should leave out "absolutely."

15208. You would say "necessary"?—Yes.

15209. But not "absolutely necessary"?—Not "absolutely necessary." It seems to make too much of a different grade of proof required in one case than in the other.

15210. (*Mr. Ram.*) It would eliminate a large number of cases if you were to keep the word "absolutely"; there are cases which you might say would be necessary?—I think it would remain purely arguable. Then a point which has probably been brought up already is that an animal which has been operated upon under anæsthetics and is allowed to recover should be allowed to be kept in any place, provided that notice of a change of place is given to the Inspector, and that the Inspector has the right of entry to the place, wherever it is. That is really in the interests of the animals; especially in the case of dogs; that is to say, if they are kept in the physiological laboratory it not infrequently happens that the place is less satisfactory than would be some place outside a town.

15211. (*Chairman.*) You mean for their recovery?—For their comfort.

15212. Do you mean by reason of the dog associating the place with the operation that it has undergone?—No; it is for their comfort and well-being.

Mr. J. N. Langley. M.A., D.Sc., F.R.S.

12 Nov. 1907.

15213. (*Sir Mackenzie Chalmers.*) You mean that your laboratories are not good places in which to keep the animals; they are necessarily rather dark and rather confined?—Yes.

15214. (*Mr. Ram.*) And you would give them a happier life elsewhere?—Yes, much happier. I have known people, for instance, who would like to take them home and see after them there, but they are not allowed to do it.

15215. (*Sir Mackenzie Chalmers.*) To give them fresher air, in fact?—Yes.

15216. (*Chairman.*) I see what you mean. You would take, I suppose, their address before they left?—Yes. Then I am inclined to think that whilst the animal under anæsthesia under a licence should, as now, be killed, of course, before recovery, anyone holding a licence ought to be able to experiment on that animal during the anæsthesia, because it would save another life.

15217. When it is going to be destroyed?—Yes.

15218. (*Mr. Ram.*) Under a lethal dose?—Yes.

15219. (*Sir Mackenzie Chalmers.*) Anyone holding a certificate, you mean?—Yes, because it merely saves another animal being killed, and, so far as that goes, I take it that is an advantage. If the animal is properly under anæsthesia, I cannot see that there is any objection to anyone who is properly licensed to do an experiment beginning at that stage instead of beginning a little earlier.

15220. (*Chairman.*) Would you have the second operation that it is to be subjected to described, as well as the first?—I think that anyone who does an operation must make a return of what he has done, but that in counting up, in the summary which gives the number of experiments, it should be counted as one experiment, because the number of experiments is to be considered as the number of animals, and you want to get the statement of the number of experiments to coincide with the facts of the case as to the number of animals which have been experimented on.

15221. (*Sir Mackenzie Chalmers.*) Or, rather, with the number of times that anæsthetics are administered. Surely it is two experiments, if you put an animal first under an anæsthetic and experiment upon it, and then let it recover, and then do a subsequent experiment?—Yes; I am talking, of course, of an animal experimented upon under a licence, and never to recover.

15222. (*Chairman.*) You mean when a dog under a licence has been given a dose of anæsthetic, from which it is never to be allowed to recover?—Yes.

15223. Whilst it is under that anæsthetic you would, if it was desirable in the interests of science, perform more than one operation?—Yes.

15224. (*Sir Mackenzie Chalmers.*) There is nothing in the Act to prevent that at present, is there?

15225. (*Chairman.*) I rather think that a witness has objected to that as illegal. (*To the Witness.*) Is there anything else you wish to say?—The last point I am not quite clear about, but apparently under the Act, a technical infringement of the Act of a very minor character may really mean an action at law with a threatening of a penalty of £50 and imprisonment. In an Act of this kind, which is to prevent pain, but at the same time to forward science and humanity, I think that no merely technical infringement should be liable to such a penalty—that it should be excluded from the Act and dealt with by the Home Office. Some of these infringements are really comparable to, say, in a Government Office, coming at 11 o'clock instead of 10. There may be ignorance of a thing, but no one would think of threatening a public employee with a fine of £50 or imprisonment for six months because by chance he came at 11 o'clock instead of 10 in the morning.

15226. (*Sir Mackenzie Chalmers.*) Practically that is secured, because no prosecution can be instituted against a licensee under the Act for anything done in contravention of the Act except by leave of the Secretary of State?—I am aware of that, but could it not be made a little more clear? I think that there are persons who are anxious to take any chance infringement of the Act, of however technical a nature, and

Mr. J. N. Langley, M.A., D.Sc., F.R.S.

12 Nov. 1907.

claim of right that under the Act, as it stands, there can be a prosecution, and therefore the Home Office ought to prosecute. It seems to me that people ought not to be put in that position.

15227. I do not think that the Act contemplates the Home Office prosecuting, because the Home Office is the authority that gives leave for a prosecution.

15228. (*Chairman.*) I think what you mean is that there might be pressure brought to bear upon the Home Office to allow a prosecution?—Yes.

15229. And you think that a prosecution in such a case ought not to be allowed?—That is so.

15230. It is not a penalty of £50 necessarily; it is not exceeding £50. However, I see what your point is. Is that all that you wish to state?—That is all.

15231. (*Sir William Collins.*) How long have you held a licence?—Since the beginning of the Act, so far as I can remember.

15232. Since 1876?—Yes.

15233. What certificates do you hold?—Certificates B, C, and E E.

15234. (*Sir Mackenzie Chalmers.*) You do not do experiments under Certificate A?—Never.

15235. (*Sir William Collins.*) And I think you told us that your experiments have been uniformly painless?—Uniformly painless.*

15236. What animals have you employed?—A variety of animals—birds, rabbits, cats, and, rarely, dogs—very rarely dogs.

15237. Could you give us any idea of the number?—Of course, they are all in the return. Last year I should think none on any of those animals which I have mentioned. All my experiments last year under Certificate B have been on frogs. Perhaps something between twenty and forty experiments, including all kinds under a licence and under certificates, in a year, including frogs, rabbits, cats, and dogs—the whole thing.

15238. And did I rightly understand you to say last year none except on frogs?—Last year and this year. (The details are in the return that I have made). I have done very few experiments except on frogs. The number varies from year to year according to the line of experiments that one is carrying out.

15239. Have you employed any dogs this year?—Two.

15240. Do you employ dogs for demonstration purposes?—No.

15241. Do you think it necessary to do so?—For some experiments I think it is necessary. These demonstrations that I give are generally on the cat and the rabbit.

15242. Do you give a complete course of physiology?—Yes, I give a complete course of physiology. Perhaps my demonstrator may show an experiment on a dog. He does some in addition to those that I do.

15243. You do not yourself employ dogs for demonstration?—In the laboratory they are used sometimes for demonstration, but it is not very common.

15244. For class demonstrations?—Yes. I should think, perhaps, one a year.

15245. For what demonstrations?—For the flow of chyle, because that can hardly be seen in any other animal than a dog, to show that after feeding there is a large amount of material passing from the various parts of the body, absorbed from the intestine and flowing into the blood, and that it is milky. The amount of the flow is a very impressive thing in absorption.

15246. (*Mr. Ram.*) Would the dog be under a lethal dose of anæsthetics?—Yes.

15247. (*Sir William Collins.*) Professor Gotch, of Oxford, told us that he did not use now dogs at Oxford for his vivisection experiments?—No doubt the practice varies in different places.

15248. I was anxious to get from you whether you think that it is essential to employ dogs for purposes of demonstration to students?—It is certainly essential if they are to understand how the lymph flows in the body that they should see it. You can explain it, but that is a thoroughly different thing from seeing that particular experiment.

15249. Is that the only experiment that you show on a dog to a class?—So far as I remember, it is the only experiment that we show to a class. We might have, for instance—I do not know that it has been done, but it might be done for the more advanced class—we might have an experiment on the vaso-dilator nerves to the lips or gums.

15250. As a matter of fact, have you demonstrated that before a class?—Not to my elementary class. Whether I have done so to the advanced class I should hardly like to say. I should have to look up my records.

15251. You have drawn a distinction between painful and painless experiments. We have been told that the Home Office returns formerly made such a distinction, but that of late years that distinction has been given up, and I understood for the reason that it was sometimes difficult to make such distinction. What do you say in regard to that?—The degree of pain is, of course, always a relative thing. I do not think that there is any severe pain in the operations of which I have any personal knowledge. There is discomfort when a wound heals; there is certain to be discomfort; and it is rather a matter of nomenclature where discomfort passes into pain. I have indicated the difference, so far as I could, by saying that some of my experiments were clearly not painful, and some of them were of the nature of a severe operation in a hospital, and those I should think possibly at times do cause pain, as they do in a human being.

15252. Your work is limited to physiological research, I understand?—Entirely.

15253. You have suggested certain possible amendments in the Act, but I did not quite gather whether you suggested that the Act itself was undesirable or should be repealed?—I would much rather have the Act than no Act. I think it would not be fair to the animals to allow anyone to experiment upon them without control. I think it is a very natural desire that there should be some control of experiments, which might, if carelessly conducted, inflict pain, and I thoroughly approve of there being some control.

15254. And you desire that anæsthesia should in all possible cases be employed?—Most certainly.

15255. And you believe that, at any rate within your own experience, it is so employed?—I believe that it is so.

15256. We were told by a lecturer on physiology, in answer to Question 14115, that the Vivisection Act was entirely opposed to the advancement of physiology, and when he was asked whether that was an opinion held by others engaged in physiological research besides himself, he replied "Yes, I think so." What do you say in regard to that?—It cannot, I suppose, be denied that the working of the Act has to some extent interfered with the advancement of physiology, because there is the difficulty and trouble of getting certificates. In research of any kind the way in which it is carried out is really to go red hot on ideas as they occur to you. If you have to wait for three weeks to get a certificate, a particular idea which occurs to you is probably never carried out, and you go on with the humdrum and immediate things which are in your line of work. If you have everything ready, then some idea which may be very fruitful you can test by observation, you can test it if you can do so at the moment, but if it has to be put off you probably never test it. So far as that goes, I suppose it would be said to interfere, but I certainly do not think that the interference with the advance of physiology has been a really serious one. Physiology has, in fact, advanced very greatly in England during the operation of this Act, and, I believe, with a diminution in the amount of pain which has been inflicted.

15257. May I take it from that that you are not of opinion that the Vivisection Act is entirely opposed to the advancement of physiology?—I should not say that it was entirely opposed. I should say that it was only partially opposed to it.

15258. A great deal of your research work has been in regard to the nervous system?—A good deal of it.

15259. And you have drawn a distinction between

* *This refers to actual experiments and operations the state after an operation is referred to in Q.* 15251.

reflex actions and conscious action in your evidence to-day?—Yes.

15260. I do not think you gave us any description or definition of what you mean by reflex actions?—If you take a sensitive plant, and you touch it, the leaf shuts up; that is one form—the simplest form of reflex action; so if you take a fragment of the nervous system, separated from all the rest, you get similar little movements of a simple character in response to external stimuli, and if you take a little more of the nervous system, or get a little more complex piece of the nervous system, you get a little more complex movement; so that one follows the reflex actions up from the plant, where they occur in a very simple form, right through the animal kingdom, and it is on the basis of comparison of the behaviour of the simplest forms of life with the most complex that I should draw the distinction between reflex actions and those which are accompanied by consciousness. Eventually consciousness can only be judged of by ourselves. We cannot have any thorough knowledge of anything conscious except as it occurs in man, and in man conscious pain only occurs when he is in possession of certain parts of the central nervous system. If those go there is no longer any power of appreciating pain. Thus you can get an absolute lack of pain where you have a body of which a portion and the nervous system is cut or where there is a lesion of part of what is called the internal capsule; this gives complete anæsthesia on the opposite side of the body. The reflex actions can then build up the mechanism out of the simple cell, but except with certain physiological structures as a basis, there can be no consciousness and no pain.

15261. Is reflex action ever conscious?—It is never conscious.

15262. So that an essential part of reflex action is that it is unconscious?—That is a necessary part of a definition except that reflexes may in their operation also set in action a portion of the brain which is concerned with consciousness, so that there may be another chain set in action, but the reflex in itself goes on in its integrity entirely and absolutely independent of consciousness.

15263. Then when you speak of reflex action, *per se* it is implied in the definition that it is an unconscious act?—It is implied. The term, of course, is often used loosely.

15264. We have often had the term "incomplete anæsthesia" mentioned in the course of the evidence; have you any definition which would attach to that?—If it was incomplete, I should usually say that sufficient anæsthetic had not been given; but those words are not used with very great scientific accuracy.

15265. It is not a recognised physiological term?—I do not think we use it in pure physiology with any frequency.

15266. I understand you to say that the margin between the disappearance of consciousness and the disappearance of reflexes under anæsthesia was different in animals, and different with anæsthetics.

15267. Is that margin very much greater in the case of animals than in that of man?—Much greater. With chloroform you have to watch very carefully to prevent the respiration stopping, which is part of the reflex really, and not conscious; it does not give rise to ordinary sensation unless you attend to it.

15268. Would the teaching to students of anæsthesia in animals be of use in their carrying on such practice in the case of a man, or is the difference in this margin so considerable that it would make it unwise to use such instruction?—I think that would depend upon the intelligence of the student. With a good student I think it would be a great advantage to him, but with a student who would go simply by rule of thumb, it might be rather dangerous.

15269. One witness suggested to us that hypnotism might be employed in lieu of anæsthetics on animals. What would you say with regard to that?—I have done a good deal of hypnotism, but I never succeeded in hypnotising an animal or a lunatic.

15270. The lecturer on physiology at Guy's Hospital said, at Question 14149: "I say that the introduction of an anæsthetic may produce complications, so that more experiments may be necessary than if the experiment were done on the animal in a condition of hypnotism, which I offered to show to the Commissioners. That, I think, is one very important point. These animals pass into a condition, so far as one can see, comparable with hypnotism. If you give them anæsthetics you are introducing a complication which you could remove, and therefore, without anæsthetics, you actually save life and actually diminish the infliction of pain." What do you say with regard to that?—You can produce a condition which is similar to that of hypnotism in man in animals, but in an animal that condition cannot be maintained for more than a short time; in certain animals it cannot be maintained for more than a few minutes, and it is always uncertain; you could never rely upon keeping it up. It is not a condition in which you could operate on an animal. In a dog, so far as I know, it has never been produced at all. It is done with pigeons and with other birds and with frogs, but no serious operation could, in my opinion, be performed on an animal in a state of hypnotism. I should be extremely interested to see the condition of an animal where anyone would suggest that you could really substitute hypnotism for anæsthesia.

Mr. J. N. Langley, M.A., D.Sc., F.R.S.

12 Nov. 1907.

15271. The same witness, in answer to Questions 14119 to 14121, gave the following evidence: "Did I rightly gather that in your opinion anæsthetics are unnecessary?—(A.) Yes, I am convinced that they are unnecessary, not only in the case of animals but of men. (Q.) For vivisection and for surgical operations?—(A.) For vivisection and for surgical operations, and I mentioned the case of midwifery. (Q.) Would it be going too far if I were to express your opinion as being that pain is a good thing in itself?—(A.) I say that pain is a beneficent and protective mechanism. I have written that in an article which I have recently published, and I am prepared to defend it. It is not a new view, of course, at all, it is recognised by surgeons, I believe, that a certain amount of pain is a protective mechanism." Is that a view that is generally held by physiologists?—There are two points there, the one with regard to the application of hypnotism to animals, the other with regard to the beneficent action of pain.

15272. Hypnotism was not mentioned in the last questions that I read to you?—In the development of the race pain, of course, has been of value, but what we are all hoping to do at the present time is to diminish the amount of pain in the universe as much as possible. Its beneficence has narrow and restricted limits. In the struggle for evolution, no doubt some excess of pain was almost necessary for the selection of certain individuals from others, but as things are now, I think it can only be said that the less pain there is in the world the better it would be. That seems to me a perfect truism.

15273. Then are you, or are you not, of opinion that for vivisection and for surgical operations, anæsthetics are necessary?—I think that they are entirely necessary.

15274. The return of movements in an animal or in man under an anæsthetic might, or might not, be indicative of returning consciousness, I gather from what you have told us?—The first movements which return after complete anæsthesia will always be unaccompanied by consciousness. The later movements may or may not be accompanied by consciousness.

15275. But in ordinary surgical anæsthesia is not the return of movement not infrequently a reason for administering more anæsthetics?—Yes, it is the beginning sign that more is required, but not that consciousness has returned.

15276. In regard to surgical operations for reuniting a nerve which has been severed, and other experiments to which you referred, do I rightly understand you to say that they have all been dervied from vivisection?—Certainly not. The main leading things have been derived from vivisection, and they have suggested operations on man. The two have been going on concurrently ever since the beginning of the work.

15277. Do you trace the ordinary union of a divided nerve directly to vivisection experiments?—The adoption of it by the surgical profession as a practice was due to the advocacy of it by prominent physicians and surgeons on the basis of vivisection. People had tried the thing long before. I suppose that from the time of the Greeks you will probably find some evidence of surgical operations on the nerves, but up to the end of the last century there were many different views about it, and the prevalent medical view was that it was impossible to cause regeneration of the nerve; and the thing which turned the tide and really directed attention was the early experiments of Cruickshank, Houghton and Fontana.

15278. What date do you put upon them?—From 1770 to 1822.

Mr. J. N. Langley, M.A., D.Sc., F.R.S.

12 Nov. 1907.

15279. You said that the erroneous opinion of Galen had been refuted by these experiments, as I understood you?—Yes, that is putting the thing in a concise fashion.

15280. Should I be wrong in thinking that Galen's opinions, whatever they may have been worth, were not derived from experiments upon animals?—I am afraid I could not offer any opinion as to where Galen derived his opinions from; I know so little about him.

15281. I see that the last Royal Commission says that Galen, in his writings, describes with painful particularity a great number of different kinds of tables which he had on which animals might be fastened, and severe experiments, which he describes, might be performed upon them. Apparently Galen's views, whether right or wrong, were derived from experiments on animals?—Does it say that this particular view of his was derived from experiments on animals?

15282. I was merely asking, as you referred to Galen, whether your attention has been called to that particular passage in the Report of the last Royal Commission?—It may well be that Galen's attention was directed to other points.

15283. When was the first successful reunion of a divided nerve for surgical purposes?—I think it would be impossible to say.

15284. Have you made any researches to ascertain that?—Yes, but the facts are scattered in so many medical papers; there are thousands of papers (of course, there were fewer in the earlier times), that it would take years to settle that point, I think.

15285. Was it a well-understood procedure thirty years ago?—Yes.

15286. Is the regeneration of nerve fibre fully ascertained now?—There are some theoretical conclusions which are still very much in dispute as to how exactly it takes place, but the general facts of regeneration are well established now.

15287. Are there not two rival schools known as the central and peripheral schools respectively?—Yes.

15288. Are you able to decide between them?—I have my own opinion, but I do not suppose that I should convince the other people.

15289. Are you a centralist on a periphalist?—I am less certain than most people, but so far as I go, I am a centralist.

15290. The researches of Ballance to which you have referred rather tended in the opposite direction, did they not?—They did.

15291. Have both schools appealed to experiments on animals for verification?—Yes, both of them.

15292. (*Sir Mackenzie Chalmers.*) I think you are a pure physiologist?—Yes.

15293. You are not a medical man?—No.

15294. Is there a school of physiologists springing up in England who are not medical men—who go in for physiology as a profession, so to speak?—Partly as a profession, and partly because they are men with independent means, who are interested in research for its own sake, and are able to live independently, and are not bound to go into the medical profession.

15295. The question has been raised from this point of view; it does not apply to the man who is chosen as the professor of a great university; but on what conditions ought licences to be granted to people who wish to practice physiology and have not had a medical training?—If they have had a scientific training I should have thought that that was perfectly sufficient. If they have been through courses of physiology in a laboratory, and are working where others are already conducting research, I think every precaution would be taken that there would be no misuse if a licence or certificates were given them.

15296. Do you think that you would have the same guarantees for care and humanity as you would have in the case of a member of the medical profession?—Naturally you cannot have exactly the same guarantees at the beginning as you can after experience; but I think that the guarantees are adequate. I think it would be exceedingly rare that there would be any misuse of the power.

15297. You think that the present authorities who recommend for a licence or grant a certificate have the means of ascertaining the character and experience of a man before they send in their recommendations?—One of those who signs the certificates, I take it, in nearly all cases knows enough to be able to state that the experiments will be conducted with care and proper precautions, but not necessarily both of those who sign.

15298. Another point that has been raised before us is this: It has been suggested that senior students who are going eventually to be teachers of physiology should have licences authorising them to perform experiments on animals under the supervision of the recognised head of the laboratory. Is that important or not, in your opinion?—The object being to fit them for research, or to fit them for study, or to fit them for a medical career? They are rather different aspects.

15299. It may be one or the other. Every one has to begin performing experiments. The question is whether it would be right that a, so to speak, partial licence should be given to a man who is a student to begin, not on his own account, but actually to do the operations himself under the supervision and teaching of a professor?—Yes, I think so, if care is taken that he is supervised.

15300. It was suggested by one witness that the proper precautions would be these: That the animal should be anæsthetised by the professor, that in an anæsthetised condition it should be handed over to the student manually to do the operation, with the professor supervising and seeing that the anæsthesia was kept up?—I think that for many students it would be extremely useful, and if it were conducted in that way I do not think that there would be any danger of any pain being inflicted by lack of knowledge or carelessness; but I do not think that I would give indiscriminate licences to students merely to practice.

15301. No, certainly not. But do you think that, under those precautions, there would be any real, substantial advantage gained? Do you think it is at all necessary?—I think there would be an advantage gained.

15302. I want to ask you one or two questions about Certificate B. You have told us that not merely the initial operation, but the whole of the operation, was performed under anæsthetics?—Yes.

15303. And then the animal allowed to recover?—Yes.

15304. Was it your practice, or is it within your experience, that when the animal is allowed to recover there are any supplementary operations ever required?—None, in my experience.

15305. It is not necessary again to put the animal under anæsthesia; so far as you have been concerned it was not necessary to do any further experiments upon it?—I can conceive that there might be such a case. I cannot recall any case of my own* in which it was necessary to give anæsthetics again, or to do anything with the animal until it was killed under the anæsthesia.

15306. If, after an animal has been allowed to recover under Certificate B, it is found to be suffering, what do you do with it?—It is killed. With regard to your former question, one might, for instance, in nerve surgery, want to give anæsthesia again, and to cut the nerve again, and leave it to recover a second time. That is to say, having observed regeneration, it might be necessary, in order to see how much fibre had regenerated, to cut the nerve and then observe the tracks under the microscope after they had been altered by the process of degeneration; so that there a second operation and a second giving of anæsthesia would be necessary.

15307. As you construe the certificate, if that had to be done, anæsthesia would be applied again as a matter of course?—Yes.

15308. It has been suggested to us by some witnesses that certain animals, having very much more acute sight and hearing than human beings, have also a more acute sense of pain. Is there any justification for that suggestion?—Every-day experience of the behaviour of animals which have large gashes and skin wounds is directly opposite to that. I should say that that is a question on which every one can form his own opinion.

15309. Physiologically, is there any connection between either the senses of sight, hearing, or smell, and the sense of pain?—Physiologically, all the apparatus for discerning pain is much less in the lower animals than it is in the higher.

15310. You may have increased sensitiveness of

* *On reference I find that I have, in a few cases, given anæsthetics a second time, in investigation on nerve degeneration and regeneration.*

hearing and of sight quite independently of that of the perception of pain?—Quite.

15311. In your experiments I suppose that you use general anæsthesia, not local anæsthesia?—I generally use the A.C.E. mixture.

15312. Taking the A.C.E. mixture or taking chloroform by itself, does the animal suddenly pass from acute sensitiveness to pain to absence of pain, or is it a slowly progressive diminution?—It is a very gradual process, beginning with diminution of the power of feeling pain, and going on to disappearance of pain, and then a gradual diminution of consciousness, and so a gradual action on all the rest of the nervous system. It is gradual throughout.

15313. There is no sudden crossing of the gap between consciousness of pain and unconsciousness of pain?—No, none.

15314. Have you by chance read Miss Hageby's evidence of some physiological demonstrations which she saw in London University?—I have looked through her evidence. I cannot say that I have read it.

15315. Her impression was that the animals there were imperfectly anæsthetised, because she saw certain movements. Can you form any opinion yourself as to whether those movements were reflex or conscious movements?—From what I have seen myself in Professor Starling's laboratory, I should feel certain that they were reflex movements. But I have not read the exact account with sufficient care to give evidence upon it, and can only answer upon general grounds.

15316. You have told us that your own experiments have been chiefly on nerves. There are many nerves, I suppose, which are wholly unconnected with the sensation of pain, which you can stimulate without producing pain?—Certainly.

15317. But are the nerves themselves which are not the subjects of pain so inextricably woven up with other nerves which are there, that you cannot stimulate them without causing pain?—If a nerve that is severed from the central nervous system is stimulated, it cannot by any possibility cause pain. The majority of stimulations in experiments on animals are stimulations of the peripheral end after it has been cut away from the central end.

15318. (*Mr. Ram.*) And that has no sensation?—It has absolutely no sensation. It is impossible that it should have any sensation.

15319. (*Sir Mackenzie Chalmers.*) We have been told by some witnesses that in operations on animals which involve opening the intestines, the intestines themselves are very slightly sensitive. Is that so?—In ordinary cutting operations they are always insensitive, and it is difficult to find that they react at all in such cases as cutting with the knife. On the other hand, it is known that when they are in an inflammatory condition, they are painful.

15320. For instance, the intense pain of peritonitis?—Yes, that, I take it, is one of the most painful diseases, but there are numerous instances in which the intestine is cut under very light anæsthesia, just over the border of loss of consciousness, when it produces no indication at all that severe pain such as might cause a return of consciousness is produced, there is nothing there to indicate that the section or suture of the intestine is capable of giving rise to pain.

15321. Then in these insensitive internal organs, how do you get intense pain of cramps, the cramps of cholera, for instance?—In that case, they seem to be sensitive to a particular kind of stimulus which one may regard as a special stimulus of the intestine; thus a certain degree of strong contraction causes pain, but cutting and burning are not painful as a rule in the viscera.

15322. Are the same nerves sensitive both to heat and cold and to pain?—No, I think they are a different set. That is one of the questions on which there is considerable difference of opinion still as to whether where the stimulus increases in intensity in a nerve which gives rise to cold, say, or to heat, and then it passes into pain; or whether there is a different form of nerve fibre which comes into action when pain is concerned. That is a matter which is not definitely settled, but in which the balance of opinion is in favour of a specific different kind of nerve.

15323. (*Sir William Collins.*) Do you mean a morphological difference of fibre?—No doubt it is connected with morphology—that one kind of nerve cannot give rise to pain under any circumstances, it only gives rise to cold; and that a nerve which gives rise to pain cannot under any circumstances give rise to cold, it only gives rise to pain.

Mr. J. N. Langley. M.A., D.Sc., F.R.S.

12 Nov. 1907.

15324. (*Sir Mackenzie Chalmers.*) The two are so closely interwoven, then, that you cannot separate them?—They run together, and it is difficult to separate them. You can get little points of the skin which only feel cold, and other little points which only feel pain or pressure.

15325. It was suggested by a witness last week that in certain cases a slightly painful operation is preferable to the use of anæsthetics. I suppose that often in mankind that is very common?—I should think it was common, and I think that it is so in some experiments on animals—all those very slight experiments. It is obvious that the puncture of a needle is perfectly trivial, whereas the giving of anæsthetics is generally accompanied by discomfort.

15326. It depends, therefore, upon the nature of the operation whether an anæsthetic should be given or not?—Yes.

15327. But I suppose you would say that as an animal cannot speak for itself, the safe thing is to give an anæsthetic whenever there is a cutting operation?—Yes, that must be regarded as a guarantee for the sake of the animal, because the infliction of discomfort, after all, is not a serious matter, whereas the casual infliction of pain is.

15328. A human being can be asked whether he would rather have the slight pain of an operation or the discomfort of an anæsthetic, whereas an animal cannot?—That is so. Where the operation is clearly not painful, as in a simple puncture with the needle, I think it is obvious that anæsthetics should not be required.

15329. That is to say, under Certificate A?—Yes.

15330. You mentioned showing certain what I may call advanced experiments to certain advanced students. Do you allow any of your students to see some of your research experiments, or only the demonstrations?—Occasionally they may see research experiments.

15331. And that obviates the necessity of having a Certificate A?—Yes.

15332. (*Mr. Ram.*) There are a few points that I want to ask you to be good enough to tell me about, please. In the nerve regeneration operations that you have told us of, would the process of healing be necessarily painful?—No.

15333. Sometimes?—I do not think that the process of healing of a nerve is ever painful unless there is inflammation, or unless there is sepsis.

15334. If you use an antiseptic there is no pain?—There is no pain, I think.

15335. You spoke of a certain number of operations in which, when the animal recovered, there would be discomfort, and of a certain other number in which the discomfort would pass into pain. What sort of operations would those be; can you indicate a specimen?—Operations on the central nervous system, I think, must generally be accompanied by some kind of pain, but certainly not always.

15336. Then the number of cases in which during recovery any pain is liable to be felt is, in your opinion, very small?—I think it is small. In the removal of a portion of an organ, for example (supposing it were endeavoured to discover with how little of an organ an animal can live with) there may be pain. I think an experiment like that, to the minimum of organ left, will probably cause some pain. Some of the experiments made in the extirpation of thyroid, which led to the introduction of thyroid treatment, I think caused pain.

15337. And would that be pain merely while the wound was healing, or even after recovery, in consequence of the altered state of the organ?—In the case of the central nervous system, it would be while the wound is healing. In the case of the removal of an organ, it might be the result of the actual removal—in the alteration in nutrition that was brought about.

15338. Then probably in that latter case the animal would be in some discomfort or pain as long as it lived?—In some cases I think it might be.

15339. What would you do yourself in your own practice in such a case as that. Should you consider yourself justified in keeping the animal alive indefinitely?—Not if it were in severe pain.

15340. You would judge of the amount of pain?—Yes.

Mr. J. N. Langley, M.A., D.Sc. F.R.S.

12 Nov. 1907.

15341. And you would put the animal out of pain if you considered the pain severe?—Yes.

15342. That, I suppose, is a matter which must be left, at all events in the present state of the law, to every operator to decide?—I think so, but, as I have said, I have never seen such a case, and I think they are rare.

15343. But if you found such a case you would your self put the animal out of its pain?—Yes. Such experiments as those are not made generally for scientific purposes, but are directed to the study of some disease which it is desired to elucidate in man.

15344. And to that end it is necessary to allow the animal to live?—It is necessary to allow the whole disease to work through.

15345. Have you ever found the inspection which at present exists under the Act any nuisance or hindrance to you?—No, I cannot say that I have found it any nuisance. The Inspector comes at irregular times and walks round the laboratory and asks to see everything that is there in the ordinary course. That takes up an hour or so in the morning.

15346. That is the only trouble?—Yes, that is the only trouble.

15347. Save in so far as there might be a hindrance to you in your work and in occupying your time, should you mind having the inspection increased?—No. Of course there is a limit. It would be a great hindrance not to be able to experiment unless someone was there.

15348. I was not upon that?—But if by an increase of inspection you mean that more people could come in at any time they liked I have no objection whatever to that.

15349. Do you think that it would be any hindrance to scientific research if an animal which had undergone an operation which might cause pain and survived was to be inspected periodically by the Inspector?—No, I think there is no reason why the Inspector should not inspect as much as he chooses.

15350. Now, with regard to morphia, if I understand you rightly, morphia not only does not prevent, but actually at times occasions reflex action?—At times it occasions reflex action; that is to say, it does not in itself occasion it, but it puts some of the lower parts of the nervous system into a condition in which they react more readily than if they are in a normal condition.

15351. Morphia given in sufficient quantities is an absolute anæsthetic?—I think it is an absolute anæsthetic.*

15352. But an animal under absolute anæsthesia from morphia would be more likely to show reflex action than under any other anæsthetic?—Most animals if you give them enough go into convulsions under morphia.

15353. Is that also the case where morphia is used in conjunction with other anæsthetics?—No, it is not the case.

15354. The other anæsthetics control the reflex action?—Yes.

15355. Now with regard to curare, in your opinion, are there certain cases in which if the necessary object is to be attained, curare must be employed?—I think it must be employed.

15356. Those cases, some witnesses have told us, are very few. Do you agree with that?—It depends upon the line of research. Taking the whole field of research they are very few; but any particular line of research might want many.

15357. It would depend upon what the object of the operation was?—Yes.

15358. And it is principally, is it not, in operations dealing with nerve investigation that curare would be necessary?—Yes.

15359. When curare is used, I rather gathered from your evidence, that many of the indiciæ of pain are absent?—They are.

15360. Therefore, as you expressed it, if I understood you rightly, the operator, in order to be sure that the animal is not suffering when under curare, must be certain that the dose he had previously given of anæsthetic is sufficient to obviate all possibility of it?—Yes.

15361. In the hands, therefore, of a careless or inexperienced administrator of anæsthetics, or operator, the presence of curare might involve suffering unperceived by the operator?—I think it would be gross carelessness, because the operator must be aware of the necessity of giving continuous anæsthetics.

15362. Do you see any objection to its being enacted that there should be a separate certificate to authorise the use of curare?—No. I think, of course, that all increase of certificates is so far a drawback that it tends to prevent people from doing experiments which they otherwise would do; but if it tended to alleviate public opinion on the question I should not in any way object.

15363. It was on that ground that I was suggesting it to you?—In itself I think it would be unfortunate, but there are many things which are unfortunate which have to be done, because of public opinion, which does not understand the thing thoroughly.

15364. For the alleviation of what I would venture to call a sensible, reasonable, public opinion, you, having regard to that, do not see any objection to having an additional certificate to authorise the use of curare?—Of course, I would rather that there were not one, because I do not think that curare is abused; but I should offer no strenuous opposition to it if it is considered advisable on what I may call the politic ground. I should only object if I thought that it might be taken to imply that curare was misused at present.

15365. Do all the animals that have curare given them die under the anæsthetic?—Yes.

15366. In no case does the operation admit of recovery?—No. There are instances recorded in the early experiments of Waterton, who discovered the poison. In practice they die under the anæsthetic.

15367. Having regard to the fact that the cases in which curare is used are comparatively few, taking the whole field, and that there is this risk of which you have spoken, do you think it would be any impediment to scientific research if it were enacted that the Inspectors should be present in all cases where curare was used?—I think it is an impracticable thing to have an inspector present when all experiments are going on, because it means that research is so retarded that it becomes practically impossible to carry it out.

15368. You observe that I limit my question to cases where curare is used?—Yes, but one never knows exactly when you want to use it in a particular kind of experiment, and the Inspector is probably not on the spot. You have to arrange weeks beforehand. In the meantime some committee meeting or something happens, so that either you cannot do the experiment, or something happens to the Inspector and he cannot come. I think it would be very difficult. And then, although in a general way I acknowledge the risk, it is on theoretical grounds. I have no reason to suppose that it is a practical thing.

15369. You have suggested as one of the alterations or improvements of the present Act the elimination of non-painful experiments, such as feeding experiments, which do not involve pain, and sub-cutaneous injections, and so forth. Could you give us any kind of definition of those experiments? Have you thought of any expression which would serve to include and express such non-painful experiments as that?—"Experiments not calculated to cause pain" I should have thought would have covered them. The Act is for those calculated to cause pain.

15370. You think that some such general expression as that would be broad enough—I should perhaps say narrow enough?—Yes—not calculated to give more pain than is caused by the prick of a needle.

15371. (*Chairman.*) Supposing that the injection causes fever?—I think I suggested the injection of non-irritating substances.

15372. (*Sir Mackenzie Chalmers.*) That would not cover the case of a substance which afterwards produces a painful disease, as, for instance, plague?—But that requires a special licence for it afterwards. But it would not require Certificate A to perform an

* *By this I mean that morphia has produced complete anæsthesia in the cases and under the conditions in which I have used it and seen it used. Beyond this I can only offer an opinion based on the statements of others; my own experiments do not cover the whole ground.*—J.N.L.

operation on an animal under anæsthetic. The experiment in that case would be one for the investigation of plague. Those experiments for the investigation of a transmissible disease seem to me to require a special certificate. The injection is an incident.

15373. (*Mr. Ram.*) The initial stage in giving an animal a sub-cutaneous injection of plague serum, say, will no doubt cause no pain to the animal, but the subsequent condition produced thereby might be very painful?—If anyone is going to investigate plague or some disease he should have a certificate, I think, that it is for the investigation of the disease, but not for the injection of a substance under the skin. It is rather striking at the wrong point.

15374. I quite follow your point. I was trying to see whether you could help us to formulate anything to carry it out.

15375. (*Sir William Collins.*) You mean a minor operation that is not followed by any morbid sequelæ?—Yes.

15376. (*Mr. Ram.*) Such as injecting a mouse or guinea-pig with milk supposed to be tuberculous?—Yes.

15377. The operation itself would not be painful at all?—No.

15378. I just throw it out in case you might be able to assist us.

15379. (*Chairman.*) One way might be to give power to the Home Office to classify certain operations as not being painful within the meaning of the Act?—Yes.

15380. (*Mr. Ram.*) I dare say if you think hereafter of any definition—you see the difficulty—you will let us know, if you can assist us to formulate anything to meet what you propose?—With pleasure.

15381. There is only one other matter, I think, I need trouble you upon. I think either in your *précis* or in your pamphlet you referred, but only made some allusion, to infantile paralysis. Is it to be hoped that these experiments with regard to nerve regeneration may be of assistance with regard to the discovery of the causes and perhaps finding the cure for infantile paralysis?—The causes are generally of a surgical nature, and are in many cases well known; but the experiments will be of benefit for the cure of the disease, or, at any rate, for the alleviation of the condition. In other words, the paralysis will be diminished or almost abolished.

15382. That is what I wanted to get at. It is pretty widespread, is it not?—There is a good deal of infantile paralysis.

15383. And when it comes in it is apt to maim or perhaps blast the whole life?—Yes.

15384. Do you think that the experiments which have been and may be made in these matters, will be likely to assist in curing or alleviating infantile paralysis?—I think so, certainly.

15385. Has anything been done in that way at present?—It is just beginning. Some experiments have been made, those that I have quoted by Frazier and others.

15386. (*Dr. Gaskell.*) I understood you to say that in demonstrating to your class you made a special point of administering anæsthetics?—Yes, they are generally shown the anæsthesia, the method in which it is produced, and the condition is pointed out.

15387. And stress is laid upon the actual condition that the animal is well under anæsthesia in consequence of the dose that has been given?—Yes. In any particular demonstration the question of the anæsthesia might be entirely left out if it has been done on a previous occasion. There would probably be one demonstration in which attention was specially called to the anæsthesia, and in a subsequent one it would be taken for granted.

15388. Have you read the past evidence before this Commission at all; have you read Mrs. Cook's evidence?—I read it just after it appeared, but I have not looked at it since.

15389. As she has brought in your name, I should just like to have a statement on your part. She says at Question 1785: "In the second volume of the 'Journal of Physiology,' page 267, will be found an account by J. N. Langley, M.A., from the Physiological Laboratory at Cambridge, of an experimental operation on a dog. The dog was narcotised with morphia. I believe I shall have expert support if I say that morphia is not an anæsthetic. The proceedings by which this dog was most cruelly tortured lasted between three and four hours"; she then describes the experiment. Have you anything to say with regard to that statement?—That is an example of the misrepresentation on which so much of the anti-vivisection opposition has been founded. There was absolutely no torture; the animal was perfectly quiet and entirely unconscious throughout. The action of morphia is not understood, of course, completely, and until we completely understand it we shall not be able to avoid this kind of misrepresentation. But there is no kind of doubt that morphia, just as it abolishes the severe pain of neuralgia, peritonitis, and other diseases in man in a small dose, can in a larger dose prevent pain in animals.

Mr. J. N. Langley, M.A., D.Sc., F.R.S.
12 Nov. 1907.

15390. There was no evidence whatever of anything in the nature of the animal being cruelly tortured or any sign of pain in that animal?—There was none.

15391. Then there is another statement: "In the 'Journal of Physiology,' volume VI., is an account of how a cat was alternately suffocated, cut, and its nerves exposed and irritated with electric shocks, without intermission, for over two hours and a half. It is stated that chloroform was given at the beginning of the operation; but it is not possible that the animal was kept in a state of insensibility for more than two hours and a half." That statement we have had put before us again and again of the impossibility of keeping an animal anæsthetised for so long a time as two and a half or three hours. Would you just tell us whether there is any truth in that?—It must be the revival of some statement made somewhere by someone who did not know what he was talking about—that animals cannot be anæsthetised and kept under anæsthesia indefinitely. I say undoubtedly that you can do it for many hours. I have seen animals untied and unfastened without producing any kind of movement in deep anæsthesia for hours together.

15392. (*Chairman.*) Was that operation on the cat one of yours?—Yes.

15393. (*Sir Mackenzie Chalmers.*) As regards that particular cat, you have no doubt whatever that during the whole of the operation it was absolutely unconscious?—I have no doubt of it whatever. If you notice the reference to nerves, all the nerves, as I have mentioned before, are those which are stimulating the peripheral end, which could not give pain.

15394. (*Dr. Gaskell.*) You suggested that when a licence has been held for ten years permission to go on experimenting should be endorsed, and no certificates required. I presume that you mean by that that during those 10 years the licence has been used continuously?—Yes, I mean that guarantees have been given of earnest work, and that the work has been conducted under conditions which have satisfied the Home Office.

15395. Do you think that as long as ten years is necessary?—No, that was merely a suggestion. I do not specify any particular term.

15396. I should like to know whether you have seen Dr. Pembrey's evidence, to which Sir William Collins referred when he was questioning you?—I have not.

15397. After the remark which Sir William Collins mentioned at Question 14115, that the Vivisection Act was entirely opposed to the advancement of physiology, the next question is: "Is that opinion held by others engaged in physiological research besides yourself," and he answers "Yes, I think so." You do not agree with that?—I certainly do not agree with that.

15398. You do not consider that Dr. Pembrey would be representative, in that respect at all events, of English physiologists?—No, I think not.

15399. Considering the question of the organisation of an animal in connection with the sensation of pain, do you think that there is any need to include cold blooded animals in the Act as at present?—I think they certainly must suffer very little, but I think again, as a matter of public policy, it is rather difficult to press for their exclusion. I do not think it would be understood. If they were excluded, and people could make experiments on them, I am not at all certain that that would satisfy public opinion. I think it would be better to have a separate certificate for cold-blooded animals, like fish and frogs, which will certainly suffer very little pain rather than to exempt them altogether from the Act. But if by your question you mean whether I think that they suffer much pain, I certainly do not think that they do. The organisation of the part of the brain

Mr. J. N. Langley, M.A., D.Sc., F.R.S.

12 Nov. 1907.

that is connected with pain in man is so small in those animals that it cannot have any very large function.

15400. Do you think that those cold-blooded animals being included in the Act somewhat hampers physiological research in this country?—I think it does, because a good many experiments could be made on frogs, and sometimes on fish, and if they require a certificate it prevents some of them from being undertaken; and, as a side point, I think that rather tends to divert attention to the higher mammals instead of concentrating it on the lower—that there might be fewer experiments on the higher mammals if there were more liberty for experimenting on the cold-blooded animals.

15401. Do you not feel yourself that in the future the study of what I may call comparative physiology is likely to come more and more to the front?—Yes, I think that is going on every day.

15402. And is not the physiology of fishes at present hardly worked at at all?—It has not been much worked at.

15403. Would you therefore recommend this Commission to consider that question of excluding those cold-blooded animals from the Act?—I certainly regard it more as a matter of public policy than of pain inflicted on the animals whethered they are included or not. It is a balance in which the amount of pain inflicted on the animals whether they are included main factors to be considered are the general public opinion upon the matter, and the degree of hindrance to research which is caused by the present Act, and that is a balance which I have not very carefully thought out.

15404. Do you not think that public opinion is mostly confined to dogs and cats, and warm-blooded animals generally?—Yes, largely. I think it is obviously absurd that cold-blooded animals should be classed under the same return of the number of experiments made with cats and dogs.

15405. Even now, at the present moment, I presume that you cannot make experiments upon tadpoles without a licence?—No, you cannot.

15406. (*Mr. Ram.*) In giving demonstrations to your students, do you instruct them as to the method of giving and the duration of anæsthetics?—In the first demonstration generally the method of giving the anæsthetic is described. After that usually the experiment only is mentioned and described.

15407. Do they see the animal put under anæsthetics?—In some cases they see the animal put under anæsthetics in the lecture room. Generally it is a question of time if that is not done, because everyone is very busy, and it takes some time.

15408. And during the demonstration, I take it that it is necessary to keep on the anæsthetic to ensure its being operative, so to speak?—Yes.

15409. And they see that?—Yes.

15410. Do you instruct them as to the necessity of keeping up the anæsthetic, and producing perfect anæsthesia the whole time?—Yes.

15411. On that, may I ask you another question? We have heard the phrase several times, "incomplete anæsthesia." Anæsthesia, according to its proper meaning, means that there is no perception of suffering at all?—No perception of suffering.

15412. Therefore, incomplete anæsthesia is a misnomer?—Yes, it is a contradiction in terms; but the meaning of anæsthesia is very varied.

15413. But anæthesia means no perception of suffering at all—that you have no ἀισθήσις. In nerve practice, anæsthesia means that there is no sense of touch, but that there is pain. Analgesia means no sense of pain. There are at least half a dozen interpretations, including Claude Bernard's.

15414. Anæsthesia means that which deprives you of all sense of pain?—Yes, that is the popular view.

15415. (*Sir William Collins.*) Is that the sense in which you have used the word in your evidence to-day?—I used it in the popular sense of absence of pain.

15416. (*Mr. Ram.*) To that extent you think that the term "incomplete anæsthesia" is a misnomer?—It is a contradiction of terms.

15417. (*Sir William Collins.*) You stated, I think, that when an animal was completely under anæsthesia, if you rapped on the table close by you produced convulsive movements?—When it is under morphia alone.

15418. Only under morphia?—The difference with morphia is that it acts very slowly on the lower nervous centres, and some of them it excites and makes more active. It has a more gradual action throughout on the lower centres from the higher to the lower, which is rapidly gone through under chloroform.

15419. That is not the case under chloroform?—No.

15420. Is that the case with man under morphia?—I have never seen an exactly parallel case of man under morphia, so that I am unable to speak from experience.

15421. (*Sir Mackenzie Chalmers.*) There was a statement made by Miss Hageby about morphia, I think, with regard to some of your experiments—it is at Questions 9266 to 9268. Will you read it, and see whether you have any comment to make upon it?—(*After referring.*) The particular experiments which are mentioned here by Wood and Cerna I have not any acquaintance with; but if the statement is intended to imply that a dog is not affected by a moderate amount of morphia infinitely less than that given on that occasion, one can only meet it with a flat contradiction. There is an experiment here by Claude Bernard, which I know, in which it is said that a dose of 30 grains was given, but Claude Bernard expressly states that 50 millegrammes * is sufficient to send an animal into profound stupor, into a condition in which cutting operations on the skin and nearly the whole of ordinary vivisection could be performed with the animal completely untied, and without any movement. That is given in Claude Bernard's "Lessons on Anæsthetics." He also mentions in his experiments the increase of excitability by a non-painful stimulus, such as by rapping on the table and by sounds. The reason why Claude Bernard gives such contradictory accounts of the action of morphia, apart from the reason that he did not know everything about it, was that he relied upon some false experiments of his own. He concluded that the increased excitability from morphia depended upon the brain, and that you did not get this increase of movement when the spinal cord alone was present. That was shown by Kölliker to be erroneous, and it is the easiest thing in the world to show that it is wrong—that this increased excitability comes from the spinal cord and not from the brain. It can be shown in the frog. A frog can be decapitated and morphia injected under the skin; in a short time the same kind of convulsive start that you have in the dog by a slight tap is produced in the frog, and this is of the same kind as is produced in man. But there are many things in the action of morphia that we do not understand; that is a second reason, apart from his erroneous experiments, why Claude Bernard makes so many contradictory statements. A third reason is that in his experiments he is making observations on each experiment as it occurs. It is not a systematic account of the action of anæsthetics; it is a description of an experiment done before an audience, with the experimenter making his deductions as he sees the things done—not in the quiet of a laboratory. Moreover, the account of the experiment was taken down by assistants; he did not write a full account himself, so that the whole form of the account is one that naturally leads to misconceptions and to contradictions.

15422. At any rate, you have no doubt that a sufficient dose of morphia is an absolute anæsthetic?—It is an analgesic.

15423. Are there cases of idiosyncrasies in animals as there are in man?—There are great differences; that is why, in experimenting with morphia, you have to take each animal and watch it.

15424. Morphia ought only to be given, then, by a very skilled physiologist; it is not so safe as chloroform or A.C.E.?—No, it is not so safe. There is a longer interval between the disappearance of pain and the disappearance of consciousness with morphia than there is in chloroform.

15425. (*Dr. Gaskell.*) Still, the disappearance of pain is easily produced; that is the main point. Pain goes quickly with morphia.

* *This is the dose mentioned for a young dog; more is required for an adult dog.*

Mr. G. Sims Woodhead, M.A., M.D., called in; and Examined.

15426. (*Chairman.*) You are a Master of Arts, a Doctor of Medicine, and Professor of Pathology in the University of Cambridge?—Yes.

15427. And you are one of the gentlemen whom the Vice-Chancellor has nominated to give evidence on behalf of the University?—Professor Langley is one, I am the other.

15428. You hold a licence, I believe?—I do.

15429. How long have you had one?—For about 24 or 25 years.

15430. You have performed during that time operations on animals?—A very large number.

15431. And you have had charge, I believe, of the work, or the principal part of the work, in pathological laboratories in the United Kingdom?—Yes; I put that in simply to indicate that I have had a somewhat wide experience.

15432. So that, at various laboratories, you have had responsibility and experience?—Yes.

15433. And for the last four or five years also you have been a member of the Royal Commission on Tuberculosis?—I have.

15434. During the time that you held a licence, have you been in the habit of performing operations in connection with pathological research?—Yes, largely in connection with pathological research.

15435. And also in teaching?—Yes.

15436. And in connection with the diagnosis of disease and the testing of antitoxins?—Yes.

15437. And what has the bulk of your work been in connection with?—In connection with the diagnosis of diseases, especially in connection with diphtheria and tuberculosis; and also in connection with the preparation of antitoxins. In addition to this, I have done work on the healing of wounds, the organisation of blood clots in vessels, the action of variolus vaccine, and the manufacture and testing of toxins and antitoxins, especially in connection with diphtheria.

15438. In connection with all those matters, have you made experiments on animals?—Yes, a very large number.

15439. And you have probably formed a very definite opinion one way or the other as to the value of experiments on animals in such matters?—A very definite opinion.

15440. What is your opinion?—My opinion is that a great deal of the work that has been done recently could not possibly have been done without having recourse to experiments on animals.

15441. Does that apply to all these different inquiries that you have just been mentioning?—Just so—to each one.

15442. Has your work on the Royal Commission on Tuberculosis confirmed you in that view?—Entirely. It would have been impossible even to undertake the work if we had not been able to use experiments on animals.

15443. Have they carried out, or caused to be carried out for them, experiments on animals for their own satisfaction during the last four or five years?—Yes, on a very extensive scale.

15444. Have they reported yet?—They have made two preliminary reports, and have issued four or five volumes of records of experiments.

15445. They have not made a final report yet?—No.

15446. But they have reported upon their experiments to a large extent?—Yes.

15447. And they have reported the evidence?—They have put forward the evidence, and their conclusions so far as that evidence will allow them to go up to the present time.

15448. I gather, then, that they attach importance, as a body, to experiments on animals?—Very great importance.

15449. Have you examined the question of the antitoxin for diphtheria by experiments?—Yes. In fact, I undertook the study of the question for the Metropolitan Asylums Board when they first commenced the work, and I carried it on for some four or five years. I saw the commencement of that work.

15450. About when was that?—1895 and 1896.

15451. Did you report to them upon it?—Yes.

Mr. G. S. Woodhead, M.A., M.D.

12 Nov. 1907.

15452. At that time were they using the antitoxin, or were they desiring your report before they used it?—They did begin to use it; but they could not get a sufficient supply, and they could not determine the strength of the antitoxin. So they asked us to determine first of all whether it was possible to measure the strength of the antitoxin; and, secondly, they asked us to prepare the antitoxin for them for the treatment of their patients.

15453. And were you to report upon the value of the antitoxin?—We did report upon its value; we were asked to prepare the antitoxin for them, and then I reported first of all that from what I could learn I considered that it was useful; then we were asked to prepare antitoxin for them, and we undertook its preparation.

15454. Was this at Cambridge?—No; this was at the laboratories of the conjoint Board of the Royal College of Physicians and Surgeons in London, where I was.

15455. Were you at that time in charge of the laboratories of the Royal College of Physicians?—Yes.

15456. Then when they asked you to prepare it, did you do so?—I did.

15457. Did you watch the results of the antitoxin of diphtheria?—Very carefully indeed.

15458. Have you done so since the years from 1895?—Yes, I made reports from 1895 to 1898. The work was then taken over by Cartwright-Wood. I also collected the statistics for 1899; but I then left for Cambridge, and have not had an opportunity of analysing all the statistics since that time. But from the year 1894 to 1898 I kept a careful record, which I now have before me.

15459. You did not keep statistics of that kind afterwards; but I suppose that you kept your eye more or less upon the question?—Yes, pretty carefully.

15460. What is the result of your experience, first up to 1898, when you were keeping this record?—I can give the statistics very shortly. In 1894 very few cases were injected, and the percentage case mortality was 29.6—practically 30 per cent.

15461. In what hospitals?—In the whole of the hospitals under the Metropolitan Asylums Board. I have the figures from the separate hospitals, which I can give you immediately. In the first antitoxin year, 1895, the case mortality had fallen to 21.5, in 1896 to 18.3, in 1897 to 17.7, and in 1898 to 13.1.

15462. Do you attribute that to the antitoxin? It is quite possible that there may have been a decrease in the virulence of diphtheria, as there often is in diseases?—Yes, that is possible. But we have two hospitals which rather took away that ground. In the Northern and Gore Hospital, where they had a large number of cases of scarlet fever—that is to say, cases that suffered from scarlet fever, and afterwards suffered from diphtheria, diphtheria bacilli being demonstrated whilst in the hospital—the case mortality amongst those was very high indeed; but when those cases were treated with the antitoxin—exactly the same set of cases—the mortality fell from something over 45.1 to 1.94 per cent.; or, if we include the similar cases at the Gore farm, 1.19.

15463. Was that between the same years, 1894 to 1898?—Yes, within that period; the fall was so tremendous that it could not be accounted for by anything else.

15464. There was a fall of rather more than 50 per cent. in the other cases?—Yes; but here it falls from over 45 to something lower than 2 per cent. In one set of figures it was between 1 and 2 per cent. In this set the cases were treated at once with the antitoxin. If the same set of cases had been allowed to go for some time untreated with the antitoxin, I have not the faintest hesitation in saying that there would have remained a very high mortality.

15465. You are speaking from those statistics. Have you yourself practised in any diphtheria hospital and watched the cases?—No, I have never watched any

Mr. G. S. Woodhead, M.A., M.D., 12 Nov. 1907.

series of cases in a hospital during the antitoxin period; but, unfortunately, I have had to watch some cases of children of friends. When I was hospital surgeon and hospital physician, of course I had from time to time cases under my charge; but that was before the antitoxin days. But, from seeing cases treated with antitoxin, and comparing them with those that I had seen in the pre-antitoxin period, I am perfectly satisfied, quite apart from statistics, that the antitoxin treatment is of great value. Although I have never practised since I held resident appointments in the Royal Edinburgh Infirmary, I have taken this question up, whenever any of the children of my friends have been attacked by diphtheria.

15466. Then you used the antitoxin in those cases?—Yes, and the results, to my mind, were far more striking than any statistics. The patients in most cases were exceedingly ill, suffering from acute toxic symptoms, which are very marked in diptheria, but in a few hours after the administration of a full dose of antitoxin their condition was quite altered. You see a patient almost livid, breathing heavily, with a very high temperature, in great discomfort, and unable to sleep. You give that patient a dose of antitoxin, and in three to four hours he is breathing easily, the skin is acting, and the patient is comfortable, and he goes to sleep. That, to my mind, is even more striking than any statistics that one can bring forward.

15467. Then you are satisfied of the benefits of the antitoxin in the case of diphtheria?—Yes. I may mention, perhaps, in passing, that in our experiments on animals carried out in connection with the testing of the potency of the antitoxin, an enormous dose of toxin may be neutralised by a dose of antitoxin, and you may see that animal recover without turning a hair, if one may put it in that way, never losing its appetite, never losing in weight, but simply going on as would a normal animal into which no toxin has been introduced.

15468. (*Mr. Ram.*) What would happen if you did not give it the antitoxin?—It would die in from 24 to 48 hours.

15469. (*Chairman.*) I gather that you are thoroughly satisfied of the value of the antitoxin in cases of diphtheria?—Absolutely.

15470. Do you think that there is any possibility of improving the antitoxin and so decreasing the mortality?—I think we have not reached finality in it. I believe, for example, that the antitoxin may be prepared in a slightly different way. We have already results from experiments on animals which indicate that. I believe that in future, instead of using the toxin only, we may use the proteids of which the organisms are made up in order to obtain something in addition to the antitoxin, and that instead of it having an antidote merely to the poison of the diphtheria bacillus, we shall be able to obtain an antidote to the specific action of the diphtheria bacillus itself. This action is local, and not so important as the toxic action; but I believe that a combination of the antidotes to two will probably be more valuable than the single antitoxin; everything is tending to prove that. I might say, in connection with the use of antitoxin in the hospitals, in order to show that it produces not merely a diminution in the virulence of cases, that in the same hospitals the percentage mortality varies very greatly in different years. For example, in the Northern Hospital the percentages were 45.1 in the pre-antitoxin year, in the Western Hospital, 37.1, in the Eastern, 30, in the South-Eastern, 29.7, in the South-Western, 28.5, and in the North-Western, 26.9. Then we find that in the last antitoxin year, 1906, in the Northern Hospital it had gone down from 45.1 to 1.94, in the Western Hospital it had gone down from 37 to 24; in the South-Western it had gone down from 28 to 22; in the South-Eastern from 29 to 22; and in the Eastern from 30 to 19. Although there was a difference in those hospitals in the different years, in all of them there was a downward tendency. This cannot be due merely to the general conditions in the hospitals. Moreover, we found that the more antitoxin was given in any hospital, and the earlier it was given, the greater was the diminution in the mortality; everything else being constant, the greatest fall in the death-rate took place where most antitoxin was given in the earliest stages of the disease, because this latter, of course, is a most important factor.

15471. You said that you kept this question of the diphtheria antitoxin as a remedy under view, although you were not engaged in preparing the statistics, but what do you say as to the use of it and the belief in it by those who attend diphtheria cases now?—All one can say is that our medical men are using more and more antitoxin every year. The worse the cases are the more anxious they are to give the antitoxin; I said before the very best results are always obtained when the antitoxin is given at an early stage, before the poison gets a thorough hold of the patient and damages the tissues. If you can give it early the death rate from diphtheria should be practically nil. The only cases that should be allowed to die are those that do not come under treatment until too late, or the few very virulent cases in which the poison seems to be so plentiful and so active that the patient is, as it were, stunned.

15472. That you believe to be the result of the use of the antitoxin?—Yes.

15473. And the antitoxin, I understand you to say, cannot be successfully tested and applied without experiments on animals?—It cannot be made, of course, without bringing some animal, usually the horse, in, and it cannot be tested without the use of guinea-pigs or some similar animal; we always use guinea-pigs. And here, of course, come in those cases of which Professor Langley has been speaking this morning. In a great many of those cases there is absolutely no suffering of any kind beyond the prick of a needle. The antitoxin neutralises the toxin so completely that you cannot tell that anything has been done to the animal; there is no swelling, no loss of appetite, and no loss of weight; the hair does not fall off, and the animal remains in perfectly good condition, and there is absolutely no pain. It is stated, of course, in our Return to the Home Office that so many thousands of experiments have been done in connection with this work, but probably in nine hundred out of every thousand there has not been the slightest discomfort even, except that produced by the prick of a needle.

15474. (*Mr. Ram.*) What is the poison which is given to the animals that are infected?—The diphtheria poison; it is the diphtheria toxin, the antitoxin being used to neutralse it.

15475. Are all animals subject to diphtheria?—Not all, but you can poison nearly most of them with the diphtheria toxin. You can poison the rat, but you must give it an enormously greater dose than is necessary to kill a guinea-pig. Animals differ greatly in this respect, and you have to determine what the requisite dose is in each case.

15476. (*Sir Mackenzie Chalmers.*) In preparing the antitoxin the horse is used?—Yes.

15477. (*Chairman.*) Have you had any experience in watching the carrying of disease by mosquitoes?—I have seen a limited number of experiments with mosquitoes, but I have followed the question very closely in connection with malaria and yellow fever, but we have of course no opportunity of studying it practically in this country.

15478. We have had many witnesses who have been engaged in it at first hand, so that it will not be necessary to ask you about it unless there is anything that you can shortly state as to your view of the value of those experiments?—I think that many of the experiments recorded are valuable as indicating how much we really owe to the method of experimentation on animals. In the case of yellow fever, although observers were not able to trace the yellow fever infective agent from man to animal, or from man to man directly through experiments, they have been able, by applying the methods which have been used in connection with other diseases, to demonstrate that the yellow fever virus is carried by the mosquito; and so satisfied were they of this, that, as we know, a member of the American Commission submitted himself to infection by that special method. Volunteers offered to live in a house with all the dirty clothes from yellow fever patients and to remain there for a considerable length of time; all came out quite unaffected. It has previously been proved that the carriage of certain organisms from the blood of birds is affected by mosquitoes, and it was suggested that this might be the method by which the infective material of yellow fever is carried from a patient suffering from yellow fever to a healthy individual. As the result of submitting himself to such infection by a mosquito—stegomyia fasciata—Dr. Carroll, a member of the Commission, and several other volunteers, contracted yellow fever. Dr. Lazear died of yellow fever.

15479. In both cases did they take it from

mosquitoes?—I am not quite sure that Dr. Lazear contracted the disease as the result of an experiment, but in Dr. Carroll's case it was undoubtedly so, and a number of the volunteer patients were infected in the same way. They simply applied in this case, on themselves, of course, the methods already proved to be of value when animals had been used. In connection with the bird parasites it was proved that they could be carried by mosquitoes, that they passed through certain phases of development in the mosquitoes, and then were transmitted to other birds. It was argued from this that it was possible that the same thing might hold good in malaria and in yellow fever, and it is now proved, I think, as clearly as anything can be proved, that that is the case. That was simply the application of the experimental method to man instead of to animals.

15480. There was no toxin that they had to administer to themselves in that case?—No.

15481. I think that the only other point on which you wish to give evidence as to the carrying of diseases through other animals is that there is still some uncertainty about its effect as it passes through the different animals?—Yes, it has been objected that different animals must be affected in a different fashion by the various diseases, and that undoubtedly is the case. We know, for example, that certain animals are affected by tuberculosis, and that other animals are not affected by it in the same degree. We know, too, that certain pus-producing organisms are very virulent for one species, but that if you pass that pus-producing organism through another species, through a whole series of animals of this second species, it gradually loses its virulence for the first, but gains in virulence for the second. We know that there are very great differences in immunity and susceptibility to various specific infective diseases, but, of course, the organisms producing them can be studied as they pass through the different animals, and I think it is very important that we should know all the phases through which these disease-producing organisms pass outside the human subject. If we cannot trace these organisms, and trace their effects outside the human organism, then we cannot tell from what point we may be attacked by these various disease-producing organisms. That has been our difficulty in connection with the work of the Royal Commission on Tuberculosis. If we can once determine exactly how disease-producing organisms act in different animals, we shall be in a much better position to understand the conditions under which we may eliminate the danger from those diseases.

15482. That, I suppose, would involve a considerable amount of experimentation?—Of course.

15483. Are the Royal Commission on Tuberculosis engaged on such experiments?—Yes, at present.

15484. Who is the Chairman of that Commission?—Sir Michael Foster was the Chairman, but he unfortunately died last year, and now the Chairman is Mr. Henry Power, of the Local Government Board.

15485. (*Sir William Collins.*) Did I rightly understand you to say that we have learnt something with regard to vaccine by experiments on animals?—The only thing, I think, that we have learnt by experiments on animals with regard to vaccine is that in all probability it is an exceedingly minute organism.

15486. Do you think that you have identified the organism?—No, I think it is ultra-microscopic. That is the opinion that I have formed. At one time I performed a large series of experiments on rabbits. Rabbits and monkeys are the only convenient two animals outside the bovine and the human subject on which one is able to raise vesicles.

15487. Was not a prize offered by the Grocers' Company for the identification of the cause of vaccine?—Yes.

15488. Has that prize ever been obtained?—Not as yet.

15489. Is that all that we have learned with regard to vaccine by experiments on animals?—Yes, I think so, except, of course, Jenner's original experiments on cattle, which are so well known to you.

15490. They were rather observations, were they not, than experiments?—That is the case.

15491. Then you dismiss the protozoal bodies which have been alleged to cause vaccine?—I do not say that I dismiss them, but I have seen no fully satisfactory evidence that they cause the vaccinal condition.

15492. At any rate, any micro-organism which may be the cause is at present invisible, and has not been identified?—Yes, I took a large series of vaccines, and I found that I could obtain the best results from those vaccines in which there were no organisms which I could cultivate or see under the microscope, in fact, that the best vaccine was that which contained no organism such as we usually recognise as the cause of one or other of these active processes.

Mr. G. S. Woodhead, M.A., M.D.

12 Nov. 1907.

15493. Not even the small bacillus which has been alleged as the cause?—I could not find that bacillus, and I came to the conclusion that, like the pleuro-pneumonia organism, and perhaps that of yellow fever, it is ultra-microscopic. It will pass through the pores of a very fine filter, but we have no microscopic appliances at present which will enable us to see it.

15494. Is it the same with regard to sheep pox and cattle plague, which were brought before the last Commission by Mr. Simon in 1876?—Did he refer to pleuro-pneumonia of cattle, or foot-and-mouth disease?

15495. The examples on which Mr. Simon thought that he had obtained exact scientific knowledge were sheep-pox and cattle plague?—If he referred to pleuro-pneumonia I do not think we have been able to find any organism yet that we could identify.

15496. If we refer to cattle plague—rinderpest?—There again we are in the same position, I think.

15497. No organism has been identified?—Not that I am aware of.

15498. And with regard to sheep-pox?—I do not know; I have not studied it.

15499. It was claimed, was it not, at one time, that an organism had been discovered, but it was subsequently repudiated?—Yes.

15500. With regard to the Tuberculosis Commission, what was the occasion of the appointment of that Commission; was it not some allegation made by Koch?—Yes; that the tuberculosis of cattle and the tuberculosis of man were different diseases—that they were not transferable from one organism to the other.

15501. Had he based that opinion upon his own investigations?—Yes, we think on an incomplete series of investigations.

15502. But investigations on animals?—Yes.

15503. You think that you have now confuted that opinion?—We have obtained a very large amount of evidence which is in opposition to some of his conclusions.

15504. Also by experiments on animals?—Yes, and we have also come to the conclusion that if we took part of our experiments only we might have come to the same conclusion that Koch came to, but taking the whole of our experiments we are satisfied that the diseases are transmissible; at any rate, that cattle tuberculosis can be transferred to the human subject. We cannot experiment directly in the opposite direction.

15505. Incidentally I understand that you have discovered, or have reason to emphasise, the great importance of soil upon the various seeds in the shape of organisms that you plant in it?—Yes.

15506. Now, as regards the antitoxin, you spoke of diphtheria in animals?—Not of diphtheria; of the toxic condition; it is not quite the same thing. You can produce the toxic symptoms in animals, but it is more difficult to produce the local symptoms.

15507. You do not reproduce the disease in animals that we know in man as diphtheria?—No, because diphtheria is primarily a local disease, and only later becomes a constitutional disease. You have, first of all, the local manifestation, the cause of the inflammation, set up in the windpipe or the upper part of the respiratory tract.

15508. To that extent then one of Koch's postulates of causation fails?—Not necessarily; you do not set up the exact kind of local condition seen in diphtheria of the human subject, but you can set up an inflammation by injecting the poison under the skin of an animal, but it does not fly to the throat; the organism does not move from point to point; it settles down at one point, where it produces its poison, and that poison is carried from that local area to the rest of the body, where it acts upon the various tissue of the body.

15509. Do you produce the false membrane in an animal?—No, because you inject the poison under the skin, and the false membrane is nothing more than the evidence of inflammation on a mucous surface; we have simply fibrin thrown out on to the inflamed surface.

Mr. G. S. Woodhead, M.A., M.D.

12 Nov. 1907.

15510. Can you produce that false membrane in an animal?—You can get the fibrin thrown out from the vessels in very acute cases of inflammation, but as it is not on a free surface it forms no false membrane.

15511. But you do not reproduce the symptoms which are familiar as the diphtheritic symptoms in man?—Only the toxic symptoms. The symptoms are due very largely to the interference with respiration in a child, but most of the toxic symptoms may be produced in an animal, just as they may be produced in a man.

15512. Is the use of the antitoxin based upon the presumption or proof that the Klebs-Loeffler bacillus is the cause of diphtheria?—Yes.

15513. We have been told that in 20 per cent. of the cases of diphtheria that organism is not found?—I think that is quite possible, because in many of those cases you have really the Klebs-Loeffler bacillus crowded out by other organisms, and you get a condition which commences as slight diphtheria, and ends as a septic sore throat. The one organism is practically crowded out by others.

15514. We have also been told that it is often found in healthy throats?—Certainly; I have found it in the throats of healthy nurses who have been attending cases of diphtheria.

15515. And even in cases which have not been in contact with diphtheria?—I have not had the opportunity of examining many such cases.

15516. You have not looked for it there?—No, but I have no doubt that organisms similar to it have been found; these, however, do not give the same toxic reactions. There are certain organisms resembling the diphtheria bacillus, but you can always distinguish between the two by determining whether they produce toxin or not.

15517. You mean the Hoffmann bacillus?—Yes.

15518. Has it not been alleged that in something like 15 per cent. of healthy throats the true Klebs-Loeffler bacillus has been found?—I certainly think it is found far more frequently than is realised; but I also think that it does not attack the throat until there is some slight inflammation, some slight breaking down of the tissues. We have, fortunately, an epithelial surface, which presents a barrier to the invasion of all these organisms, and it is only when there are slight breaches in that barrier that the organism gets in and is able to make further breaches.

15519. Where there is some lesion prior to the entrance of the organism?—Yes. If the organism were not there it would heal, and there would be no further disturbance, but if the organism is there it takes the opportunity of getting in and giving rise to very serious conditions.

15520. You cited both clinical and statistical evidence in favour of the antitoxin. What would be about the total number of the cases of diphtheria that you have yourself watched?—When I was house physician I saw a dozen perhaps.

15521. And since then?—And since then I have seen perhaps a couple of dozen. I have only been called in to special cases.

15522. About 36 cases in all?—Yes.

15523. In regard to the statistical evidence you called attention to the fact that in the pre-antitoxin days, as you call them, there was a variation from 26 per cent., I think I understood you to say, at one hospital, to 45 per cent. at another hospital in the same year of deaths from the disease?—Yes.

15524. You did not tell us whether the total number of cases of diphtheria admitted into the hospitals had increased of late years. Should I be right in thinking that that is so?—I should say that it has in London, but I can also say this—I was looking at the statistics in connection with it a short time ago—that there are now actually fewer cases of diphtheria than there used to be, and that there is not only a much lower death-rate, but a lower actual mortality taking all the large cities of the world.

15525. But taking the London figures that you quoted, should I be wrong in thinking that the numbers were very much larger in the later years than in the earlier years?—No; there are a larger number in the later years during the time that I was examining, because we came to the conclusion that they sent cases in when otherwise they would have kept them out, and also that they sent in the very bad cases in hopes that they might be cured in the hospitals.

15526. Was there not another reason? Was not the area of diagnosis extended by using swab cultures?—Not until they came in, of course. At that time we did not get swabs until the patients had come into the hospital.

15527. Do you say that nowadays cases are not diagnosed by swabs?—No doubt there may be nowadays, but I was referring simply to my own statistics.

15528. I was only asking whether in recent years there has not been an augmentation in the number of cases admitted into the Metropolitan Asylums Board Hospitals, because the area of diagnosis had been enlarged by the bacillary test as against the old clinical test?—I can state that generally, but I do not think that it is carried on on such a scale that it will make a great difference in the number of admissions. In the Cambridge outbreak Dr. Cobbett and Dr. Graham Smith examined bacteriologically practically every case that came in contact with a case of diphtheria; as a result of this method of procedure they were able to stamp out diphtheria in both epidemics. Afterwards Dr. Cobbett did the same thing at Colchester.

15529. (*Mr. Ram.*) Did they use the antitoxin?—Yes, in all cases. They examined every case which had been in contact, and injected the antitoxin wherever they found the bacillus, and so were able to stamp out the epidemic in a very short time in both places.

15530. (*Sir William Collins.*) But in regard to the London cases to which you have called our special attention, should I be wrong in thinking—I want to be quite clear—that the numbers in recent years have been considerably augmented by reason of utilising the diagnosis test of the bacillus?—From the figures to which I have called attention that does not hold. I rely only on those figures which I have had to deal with specially; those are my own work; the others I have not had any opportunity of checking.

15531. Then do you stop short at the year 1898?—Yes.

15532. Then with regard to the years up to 1898, had there been much increase in the proportion of cases treated with the antitoxin between 1895 and 1898?—Yes.

15533. Could you give us the percentage of cases treated with the antitoxin in those years?—I can give you the amount of the antitoxin sent in to the hospitals.

15534. I would rather have the number of cases treated with antitoxin?—I have no doubt that I can give you that also.*

15535. Thank you. What I want to know is whether you attribute the lower case mortality that you mentioned, 13 per cent. as against 21 in the earlier years, to the fact of the larger number of cases treated with antitoxin?—Yes, undoubtedly.

15536. I should have been glad to have the figures to complete your story?—I will let the Commission have them. I have not looked over my report except for a few points, but I may say that in 1895 we only supplied 1,200,000 units of antitoxin to the whole of the hospitals under the Board; in 1896 we sent out 25½ million units, and in 1897 we sent out 60¼ million units. That means, of course, a very largely increased number of patients treated. It ran up from, in 1895, 1,200,000, to, in 1896, 25,600,000, and in 1897 to 60,300,000.

15537. Do you happen to have followed up the case in London; do you know what the percentage case mortality now is in the London fever hospitals?—No, I do not know that it is lower.

15538. Is it much lower than 13 per cent.?—I think it is about 10 per cent.

15539. Am I right in thinking that a still larger percentage of cases is now treated with antitoxin than in 1898?—Yes.

15540. And yet the mortality has been reduced only 3 per cent. further?—It comes to a point, you see, at which it is impossible to reduce it very much. If you could get all your patients in at an early period, if you could treat them within 24 to 48 hours, I believe that you could bring the percentage down to 2 per cent.

* 3042 *cases of diphtheria were admitted in* 1894, *of these* 24 *received antitoxic serum. In* 1895 *of* 3824 *cases admitted* 2403 *were injected, and in* 1896, 3758 *cases were injected out of* 5068 *admitted.*—G.S.W.

15541. Within 48 hours of what?—Of the outbreak of the disease by the appearance of the false membrane.

15542. But you may find the bacillus and there may be no false membrane?—Yes.

15543. Is it not the case now that if the bacillus is found the antitoxin treatment follows?—Yes.

15544. Even without waiting for the false membrane?—Yes, and very wisely so. If you do that, if there should by any slight inflammation, even though the bacillus forms the toxin, and the toxin gets into the tissues and is carried away by the blood and lymph, it is neutralised and the patient is put under the most favourable conditions for recovery at once; But you do not get the patients in as a rule until there is some false membrane. If you could treat them as soon as acute inflammation appears, then I believe you would save almost every case, but if you allow the toxin to act for any length of time on the various organs of the body, you cannot neutralise the harm that has been done, though you may neutralise the poison that has done it, now of course too late.

15545. You think that by using the antitoxin the mortality of diphtheria may be reduced to nil?—Almost, if you could get the cases early enough. Our Northern and Gore Farm Hospital statistics bear this out most fully.

15546. You told us just now about stamping out certain outbreaks. That was using it as prophylactic?—Yes, using it as a prophylactic in cases where there had been contact with diphtheria patients.

15547. Is it your experience that it has been valuable as a prophylactic?—I should say, from our experience of these epidemics, that it is distinctly valuable.

15548. Have you seen a recent paper by Dr. Peters, of Nottingham, rather questioning its value as a prophylactic?—No. But I am afraid that he would have to bring forward very convincing arguments to induce me to alter my opinion under present conditions.

15549. You think that by the prophylactic use of the antitoxin, diphtheria may be abolished in this country?—If you carefully examine all the throats of all "contact" cases I think it would.

15550. The actual preparation of the antitoxin from the horse does not require a vivisection licence?—Not now. We prepared it under a vivisection licence because we did not know the legal position. In fact, it was on our application, I believe, that the matter was placed on its present footing.

15551. The production of vaccine and other commercial bodies does not require a licence under the Act?—I believe not.

15552. (*Mr. Ram.*) The specific organisms of certain diseases have not yet been found?—They have not been demonstrated.

15553. Is it your opinion that in other diseases the specific organism has been discovered?—Yes.

15554. And can be dealt with?—Yes.

15555. And with regard to what you have been telling us as to yellow fever, is it a fact that not only the specific organism can be dealt with as you have indicated, but that it has been made commercially useful as a means of stamping out yellow fever?—Yes, the statistics in Havanna are marvellous. In Havanna, from 1853 to 1900, there were 35,952 deaths. In 1900-01 there were cases varying from 308 in a single month in the seasonal period down to 5; and during the same period there were from 74 deaths in one month down to no deaths. In 1901-2, when these protective measures were put into force, only one year later there were never more than eight cases in any single month, and never more than two deaths. So that from 308 cases, with 74 deaths, there was a fall to 8 cases and 2 deaths. That was entirely the result of putting into force agencies for killing the mosquito. That was the direct outcome of experiments.

15556. That preventive result followed directly from experiments which had been made, without which the origin of the disease in the mosquito would not have been suspected?—That is so, we should not have known anything about the life history and mode of transmission of bird or malarial parasites, and our knowledge of their relation to mosquitoes not being acquired could not have been applied to the infective agents of yellow fever.

15557. One other question with regard to diphtheritic cases. Are you, in your own mind, clear that even discounting other causes which have been suggested as assisting, at any rate, in the diminution of mortality——?—Which I do believe play a part, undoubtedly.

Mr. G. S. Woodhead, M.A., M.D.

12 Nov. 1907.

15558. After discounting those other causes, are you still satisfied that the antitoxin treatment is of the greatest benefit in diphtheritic cases?—I am.

15559. Do you find that that is the opinion of the vast bulk of those practitioners who are brought in daily contact with diphtheria?—Yes.

15560. And not only is it their opinion, but is it put by them into practice?—Yes, as I know from the amount of antitoxin that is being used in the country at the present time.

15561. (*Dr. Gaskell.*) Do you use demonstrations at all with your students in your laboratory?—Not before the junior students.

15562. But for the senior students?—Yes.

15563. Do you consider that that is necessary?—I think so. Of course, I am in a specially good position, because I have to do a number of these experiments on animals, and therefore I do not do any special ones. I get the students down to see the experiments that we are carrying out—the senior students, that is to say; so that although I am not performing any special experiments for demonstration purposes, I take the opportunity of letting them see the experiments that we are doing in connection with antitoxin and in similar work.

15564. And those experiments are experiments under licence?—They are all under licence.

15565. Are you able yourself to sign applications for a licence?—No.

15566. Do you not think that you ought to be?—I think that I ought to be.

15567. Would you suggest, then, that in addition to the names of the professors of physiology, medicine, anatomy, medical jurisprudence, materia medica, and surgery, there should also be included in the Act among those people who must sign licences, the professors of pathology, bacteriology, and hygiene?—Yes, I think so, certainly.

15569. All those three ought to be included?—Certainly.

15569. That part of the Act which should be reformed?—Yes, because we really see more of this work than almost any one, except the physiologists.

15570. Is it necessary, do you think, to use the word "professor," or would "teacher" be better?—"Teacher" would be better. A year ago Dr. Nuttall, for example, would not have been able to sign as he was a reader, but he had all the responsibility of a professor as the head of a departmental laboratory.

15571. Perhaps "teacher" and the head of a laboratory would be better?—Yes.

15572. (*Chairman.*) Is there anything else you wish to bring before us?—Professor Langley has suggested that after an operation has been completed we might be allowed to take an animal from the laboratory to some place outside. At present we have to keep all the animals on the premises. Those premises are not always very commodious, and sometimes are not very well suited for animals which must necessarily be carefully looked after, and should be kept under the most hygienic conditions possible, and it would be a very great advantage if we were allowed to take the animals to some place where they may be under better conditions than in the laboratory.

15573. (*Mr. Ram.*) Leaving the address for the Inspector if he wanted to see them?—Yes, I do not wish in any way to limit inspection. I think it is a very good thing that everyone should know that everything must be carried on carefully and without any abuse.

15574. And you have found no trouble from inspection?—None at all.

15575. It has been no nuisance to you?—No.

15576. Might I ask you on that whether your view is the same as that of Professor Langley. I suggested to him, partly to meet public feeling, that in the few cases where curare was used it might be recommended perhaps that the Inspector ought to be present in order to make sure that the anæsthesia was properly complete, and so forth. Would you see any objection to that?—I think it would be a very difficult matter to have the Inspector present. I think if you cannot

Mr. G. S. Woodhead, M.A., M.D.

12 Nov. 1907.

trust a man to do experiments you must not give him a licence.

15577. Including the use of curare?—Including the use of curare.

15578. You will observe that I limited my question to that?—I should not object to a special certificate so that the Inspector might be more vigilant if it were thought necessary in order to allay public fears.

15579. And he would know of the granting of that certificate?—Yes.

15580. Would he know when it was going to be utilised?—Probably not; you could not let him know beforehand the exact hour for the performance of every experiment, but knowing that such experiments were being carried on, he would probably make it convenient to be present at some of them.

15581. (*Chairman.*) Is that all that you wish to bring before us?—There is one other matter, that is, as to the use of dogs. In this matter I should like to support what Professor Langley has put forward. It has been said that they are not useful for pathological work, but I have found on several occasions that we could not have carried out our experiments to a successful issue without recourse to the use of dogs.

15582. I think that the suggestion was that they were not necessary, not that they were not useful, but whether they were necessary?—I should say that they are necessary, even for the very experiment which Professor Langley spoke of, which we have had to perform in connection with the transmission of the tubercle bacillus from the intestine into the body that is along the lacteals. We have had to operate on the thoracic duct; that experiment has been done by a number of people in order to determine the path that the tubercle bacilli traverse in getting to various parts of the body. It is a much more complicated process than we had any idea of. It has been found necessary to trace the tubercle bacillus in the body, not only in the alimentary canal, but after it gets into the respiratory tract and the lymphatics, and so on to its invasion of the blood vessels. It is a much more complicated process than we imagined when we began our research, and one of the experiments which had to be done was the inspection of the thoracic duct for the passage of the tubercle bacillus, and we could not have done that in the same way on any other animal that I know of.

THIRTY-FIFTH DAY.

Wednesday, 13th November, 1907.

PRESENT:

The Right Hon. The Viscount SELBY (*Chairman*).

Sir W. S. CHURCH, Bart., K.C.B., M.D.
Sir W. J. COLLINS, M.P., M.D., F.R.C.S.
Sir M. D. CHALMERS, K.C.B., C.S.I.
Mr. A. J. RAM, K.C.
Mr. W. H. GASKELL, M.D., F.R.S.
Mr. J. TOMKINSON, M.P.
Mr. G. WILSON, M.D., LL.D.
Capt. C. BIGHAM, C.M.G. (*Secretary*).

Sir VICTOR HORSLEY, F.R.S., F.R.C.S., called in; and Examined.

Sir V. Horsley, F.R.S., F.R.C.S.

13 Nov. 1907.

15583. (*Chairman.*) You are a Fellow of the Royal Society and a Fellow of the Royal College of Surgeons?—Yes.

15584. And I believe you come here to give evidence before us as representing the British Medical Association?—Yes.

15585. Would you just tell us what that body is?—It is a body composed of medical practitioners. It includes about half the British medical profession, and each member subscribes 25s. a year to further the objects of the Association. The objects of the Association very briefly are to further the interests of the medical profession and the scientific knowledge of the medical profession.

15586. And they have acted in various respects in furtherance of those views in various ways?—Yes, they have. They have a Scientific Grants Committee for the express purpose of allotting a certain proportion of the subscriptions of members in the furtherance of scientific work by giving grants of money to young members to pay their expenses for the researches they conduct, and in this manner they have expended upwards of £30,000 since about 1874—since about the beginning of the administration of the Vivisection Act. I need hardly say that medical practitioners have not much money to spend, but they have, I suggest, been led to give this money out of their subscriptions because they see in their daily work the necessity of more scientific knowledge.

15587. You propose to give us your views on what you call the ethical side of vivisection and anti-vivisection?—Very briefly.

15588. Are those the views of the British Medical Association?—Yes. I can put it in almost one sentence, not to waste the time of the Commission. The medical profession consider that every effort ought to be made to increase knowledge for the prevention of suffering and disease, affecting not only man, of course, but also the lower animals; and they consider that anyone who opposes such pursuit of knowledge is acting immorally. To them the moral duty is the pursuit of knowledge, and an immoral act is the obstruction of that pursuit of knowledge. I would compare in this particular the fact that of their own moneys they have subscribed this large sum of £30,000 for the pursuit of knowledge, while of the anti-vivisection party, Mr. Coleridge's Society, to take that alone, have collected from the public £86,000 and have not added one item of knowledge to us for the relief of suffering or the prevention of disease.

15589. I understand that you desire, in reference to this point, to call attention to Mr. Coleridge's evidence?—I do. But before I leave that point may I also draw the attention of the Commissioners to the fact that several witnesses have spoken as though the anti-vivisection party were morally justified in accepting the knowledge gained by vivisection. May I point out to you that it has always been the feeling of the profession that the anti-vivisectionists were not morally justified in accepting knowledge thus gained. The profession would, in fact, regard it thus: that if the anti-vivisection party consider that facts have, as it were, been immorally obtained from Nature, stolen from Nature, the persons who benefit thereby are practically receivers of the stolen facts, and they suggest that the legal position of the moral responsibility of a receiver being almost as bad as that of the thief holds in this particular.

15590. But how would you deal with the question? It is said, and I think generally believed, though it is disputed, that Harvey discovered the circulation of the blood by experiments on animals?—Certainly.

15591. Does that, do you mean, bind everybody in the present day not to be an anti-vivisectionist?—Certainly.

15592. Because it is impossible for him to avoid the conclusions arrived at?—Exactly, and in that connection I have placed upon my *précis* a very brief reference to the Anti-Vivisection Hospital, because the money for that hospital was originally collected many years ago, by Mr. Coleridge's society in part, on the idea that medical practice could be conducted without any reference to vivisection.

15593. Vivisection past or present you mean?—Past or present; whereas we know of course that no one feels the pulse of a patient and derives any information therefrom without being indebted to vivisection. Morally speaking, it seems to me (I am only giving my own personal opinion, of course) that the anti-vivisectionists have no right to derive benefit from experiments upon animals.

15594. Holding the views that they do?—Holding the views that they do. I would add that the Editor

of the "Zoophilist," one of Mr. Coleridge's employees, Dr. Berdoe, stated in the "Times" that he would rather be treated with a knowledge of Hippocrates than the knowledge of the present day. I can only say as a commentary on that that from my own personal experience he does not rely on the knowledge of Hippocrates, but he sends his own family to receive the opinions of men like myself. However, I pass from that, my lord, and pass now to the single example that I have selected to illustrate the action of the British Medical Association in promoting the pursuit of knowledge, and I have taken the instance of the Pasteur Institute as being also a subject of considerable controversy and object of attack by the anti-vivisectionist party. In the evidence of Mr. Stephen Coleridge, on page 144, line 14, Mr. Coleridge used these words, "The first striking achievement of my society, with which I had the honour to be associated, was the prevention of a public meeting held at the Mansion House" (it should obviously be "to be held') "in 1889, the object of which was to start a fund to erect a Pasteur Institute in England. We prevented that public meeting taking place, and the result was that no Pasteur Institute was set up. England to-day is, I believe, one of the few European countries of importance that is spared a Pasteur Institute, and in England there is no rabies." Now the freedom of England from rabies I take to be one of the great achievements of modern science, and we owe it entirely to M. Pasteur. The position is as follows: In the first place Mr. Coleridge informs the Commission that that meeting was prevented by his Society from taking place. It is not so. The meeting took place at the Mansion House, the Lord Mayor in the chair, on the 1st July, 1889. In the second place, the object was not as he states it; it was not called for the purpose of establishing a Pasteur Institute in England, it was called "for the purpose of hearing statements from Sir James Paget and other representatives of scientific and medical opinion with regard to the recent increase of rabies in this country, and as to the efficiency of the treatment discovered by M. Pasteur for the prevention of hydrophobia." At that meeting speeches were made and resolutions were passed in favour of thanking M. Pasteur for the treatment that he had given to English patients, and then another resolution that I had the honour of moving was as follows: "Professor Horsley proposed, and Dr. Farquharson, M.P., seconded, a resolution to the effect that rabies might be stamped out of these islands, and inviting the Government 'to introduce without delay a Bill for the simultaneous muzzling of all dogs throughout the British Islands as provided in the measure drafted by the Society for the Prevention of Hydrophobia, and for the establishment of quarantine for a reasonable period of all dogs imported.'" I had the honour of acting as secretary of a Committee that was appointed by the Government to inquire into M. Pasteur's treatment, and when the Committee was in Paris M. Pasteur said to us, "Why do you come here to study my method of a curative for inoculation? You do not require it in England at all. I have proved that this in an infectious disease; all you have to do is to establish a brief quarantine covering the incubation period, muzzle all your dogs at the present moment, and in a few years you will be free." When the Committee returned and reported to the Houses of Parliament, this point of course was always before us, and I moved that resolution with the sympathy of the Committee appointed by our Government.

15595. You mean that you had no intention in calling the meeting to set up a Pasteur Institute for the treatment of rabies?—No.

15596. And no such proposal was made?—No such proposal was made at all.

15597. Your resolution I suppose was carried?—Yes, they were all carried. Immediately this point of universal muzzling was raised the anti-vivisection party, Mr. Coleridge's Society in particular, entered upon a virulent campaign against us, and held meetings and endeavoured to show that M. Pasteur's discovery of the real infective nature of the disease was wrong; they revived the old ideas that it was lunacy in dogs, that it was not a disease, and they revived also the particularly dangerous idea (from the public point of view) that it could spontaneously generate in the dog; whereas M. Pasteur had proved that the exact opposite was the case. I need not weary the Commission, but I would point out that we obtained partial muzzling in spite of this opposition, and that that did so much good that then Mr. Walter Long applied the muzzling universally and established quarantine.

15598. First they had the power to muzzle by counties?—Yes; and in the County of London, I showed from the records of the Brown Institution, the laboratory of which I then directed, that the effect was wonderful in immediately cutting down our admissions of rabies, and that it also cut down another contagious disease—distemper, which, you will understand, is due to a respiratory infection. The effect of that was that Mr. Walter Long, when he was at the Board of Agriculture, imposed a universal muzzling and brief quarantine, with the result that, fortunately, now the United Kingdom is free from rabies, and that is the only correct statement in that passage I have read. But it is not due to anything really but the scientific knowledge that we derived on the subject of rabies.

15599. You say that there were two resolutions passed at that meeting—one thanking M. Pasteur for his discovery and labours, and the other in favour of muzzling dogs?—The universal muzzling.

15600. I understand that Mr. Coleridge and his Society attacked the first resolution. Did they also oppose the second?—Yes; they attacked both.

15601. They attacked muzzling as being what—unnecessary?—They attacked muzzling vigorously as being cruelty to the dog and being unkind, because the disease, as they said, could arise spontaneously; therefore, what was the good of muzzling dogs? May I add that subscriptions were collected at that Mansion House meeting, and later on this country sent 40,000 francs to M. Pasteur as a token of the work he had done for British subjects.

15602. Do you say that the desirability and the efficacy of muzzling dogs were proved by Pasteur by experiments on animals?—Yes, certainly.

15603. What sort of experiments?—By his inoculation experiments on animals, which for the first time proved the existence of a distinct virus and of its transmissibility to different animals. Up to that time these really absurd ideas prevailed that it could be spontaneously generated, that it was not a contagious disease at all, that it was really lunacy in the dog and insanity. It required the scientific investigation of M. Pasteur to demolish that. Of course anybody who had had personal experience of rabies in dogs recognised that it was a contagious disease, and that M. Pasteur was quite right. But all the action of the authorities previously had been in ignorance of the proved fact. That is the first point that I wanted to draw the attention of the Commission to, and I should add that the British Medical Association sent a special deputation of their Scientific Grants Committee to that meeting to express the feeling of the profession as to the value of M. Pasteur's work.

15604. As it seems rather important on the question that we have to report upon, could you refer us to any action taken by the National Anti-Vivisection Society against muzzling?—Yes, I could find it, of course.*

* Sir Victor Horsley subsequently forwarded the following note:—

"*The responsibility of originating and fomenting an agitation against the use of the muzzle to stamp out hydrophobia rests wholly on the anti-vivisection party as shown by the following facts:—*

"*After the issue in 1887 of the Report of the Committee appointed by the Local Government Board to enquire into M. Pasteur's treatment of hydrophobia, and in which the general application of the muzzle was strongly advocated, Miss Francis Power Cobbe, the leader and organiser of Mr. Coleridge's Anti-Vivisection Society, began an anti-muzzling agitation.*

"*One of her pamphlets entitled "The Amendment of the Dog Laws" was published by a small body of antivi-visectionists organised by one of the Executive Committee of Mr. Coleridge's Society, namely, Mr. Pirkis, and though this body was never recognised by the dog breeders and owners of the country and was but an offshoot of Mr. Coleridge's Society, it styled itself "The Dog Owners' Protection Association." Lord Mount Temple introduced into the House of Lords a Bill on their behalf in opposition to a Muzzling Bill introduced by the Society for the Prevention of Hydrophobia. The agitation reached a culminating point on November 25th, 1889, when a public meeting was called by leading members of Mr. Coleridge's Society, Surgeon-General Gordon and others, to protest against the muzzling regulations, at the time when the London County Council was pressing the Privy Council to apply them generally.*

"*At the meeting, however, a resolution was carried by a large majority in favour of muzzling. After this the agitation gradually died out, although an attempt was made to revive it when Mr. Long subsequently issued his Order.*"—

VICTOR HORSLEY.

Sir V. Horsley, F.R.S., F.R.C.S. — 13 Nov. 1907.

15605. Thank you, if you would?—The action of the anti-vivisection party in that respect we consider to have been immoral. We consider that it was opposing the results gained by the scientific research, that those results were of value to the human community, and also to the lower animals; and that that opposition was immoral. I have also brought the incident before you because there are a great many passages in this evidence by Mr. Coleridge to which I should like to take similar exception; but this was such a striking contradiction of the actual fact that that is why I have taken it as an example of the rest. I propose now to pass to the next part of my *précis*.

15606. If you please?—The second part of my *précis* deals with the question of teaching students by means of experiments on animals. I desire to lay before the Commission the view that such teaching is desirable in the following subjects:—Physiology, pathology, pharmacology, and surgery; because, with the exception of the third I have had experience in teaching each of these subjects. In the first place I would suggest that Sub-section (5) of Section 3 of the Act should be repealed. It is in effect abrogated in the Act by the second part of Section 3, because experiments may be shown to students in illustration of lectures under a special certificate, but as I hope to conclude by persuading the Commission that the certificate system has so many faults that we should get rid of it, may I suggest also that the recommendation should be that this Sub-section (5) of Section 3 should be repealed. That is the first point. The argument in favour of such repealing of Sub-section (5) would be, of course, an argument against the so-called disadvantages of showing experiments to students, and therefore very briefly I would allude to the evidence which has been given by Sir Thornley Stoker, at Questions 761 and 1051, because it is quite evident that that evidence was offered by Sir Thornley Stoker in complete ignorance of the subject. He says at Question 761, page 32, two-thirds of the way down the columns, after reference to the Act: "I am strongly of opinion that . . . experiments on living animals should be forbidden in illustration of lectures, on the ground of their uselessness, and, perhaps, cruelty also." I think that Sir Thornley Stoker's further evidence, in which he informed the Commission that he was cruel in early life shows that his education as a student had been neglected by his not witnessing experiments on animals, because I think it would have assisted him in becoming more humane, and, at any rate, would have certainly prevented him from giving expression to such an opinion as this. He then goes on to say: "Such demonstrations cannot but be demoralising to the young men and women who witness their performance. They seem to be an offence against humanity." Then also Mr. Coleridge referred at length to this in Questions 11372 and 11396. All I can say is that I have shown a very large number of experiments to students, that they have always evinced the utmost interest in them, and they have told me that the facts which the experiment illustrated have been imprinted upon their memory in a way that they could not have obtained by any other means; in fact, they have simply emphasised the statement of Professor Huxley before the 1876 Royal Commission, where he said: "There is no teaching of physical science worth anything as thorough teaching unless it is accompanied by practical instruction." And I unhesitatingly affirm that there is no demoralisation whatever such as has been suggested to this Commission by Sir Thornley Stoker and by Mr. Coleridge. May I also, in speaking of the previous Royal Commission, draw your attention to the fact that in the report of that Commission, on page 17, the Commissioners say: "The evidence we have quoted above seems to show conclusively that at the medical schools where such demonstrations are exhibited under anæsthetics the sense of humanity in the students is not in fact impaired." I have nothing to add to that statement; it is as true now as it was 30 years ago. I suppose, however, that the Commission would expect me to justify my suggestion in a little detail. I therefore would point out that for instance in physiology, I think it is most essential that students should see, and in fact the senior students perform, an experiment on a warm-blooded animal—a mammalian animal—on the heart and the circulation. I choose that as an example. I am sure that no one can acquire a proper knowledge of the action of the heart or of the real phenomena of the pressure of the blood within the vessels unless he has witnessed, and indeed taken part in such an experiment.

15607. Have demonstrations of that description to show the circulation of the blood in living animals been common in past times or are they only of the present time?—I entered as medical student at University College in 1876 when this Act began its operations, and Professor Burdon Sanderson in that year showed us these experiments.

15608. Under the Act?—Yes, he gave us about a dozen, I think, demonstrations on animals during the session.

15609. Supposing that you took 20 or 30 years earlier than that; were demonstrations used then?—I do not know. I should hardly think they were.

15610. Dr. Burdon Sanderson is dead now?—Yes, he is dead.

15611. He was a very strong advocate of demonstrations, was he not?—Yes, he instituted the practical class in microscopic anatomy with Professor Michael Foster, who is now dead; but I think Professor Sharpey also gave demonstrations at University College before Professor Burdon Sanderson.

15612. I am only asking the question with reference to what you would say as to the comparative knowledge of medical men of the present day and of medical men, say, 50 years ago on such a matter as the circulation?—Of course, at the present time we have greatly increased knowledge. Take this question of the blood pressure, for instance the actual pressure of the blood; we now measure it accurately in the human being, and it is one of the essential phenomena which indicate to us the condition of shock after a surgical operation. The question of the pressure of the blood is going to be unquestionably one of the cardinal points in this great question of surgical shock.

15613. You mean that a much more detailed and accurate knowledge of the circulation has been obtained?—Yes.

15614. And therefore is a necessary equipment of the modern doctor?—Absolutely. When I was a student the blood pressure was looked upon as a scientific amusement, as it were—I mean by many practising physicians and surgeons. They took no heed of it; they never attempted to measure it, and I may say they did not attend the demonstrations of Sir John Burdon Sanderson. The next subject is pathology. I wish to point out that having lectured on pathology, and having illustrated my lectures by experiments on animals, the necessity of this method of teaching students has been borne in upon me very closely. As an example I have chosen epilepsy with convulsions of all kinds as being a very common form of disease, and yet one which the student has no means of analysing in ordinary hospital work, and very often hardly sees a patient in a fit at all. And yet epilepsy, for instance, can be reproduced experimentally with absolute fidelity by the simple injection into the veins of a drop of essence of absinthe. In 25 seconds you have a typical epileptic fit produced, and a student who has once seen it, and watched it develop through the body of the animal never could forget, and never has forgotten it.

15615. (*Sir Mackenzie Chalmers.*) Is that the ordinary absinthe of commerce?—It is the pure essence which is diluted for the drink of vermouth. It is extremely toxic.

15616. (*Mr. Ram.*) Would the animal be under anæsthetics?—Entirely.

15617. The anæsthetics would not interfere with the development of the epileptic symptoms?—No.

15618. (*Chairman.*) Nor would the animal be allowed to recover?—No.

15619. (*Dr. Wilson.*) Do you distinguish in that case between epilepsy and convulsions?—No, I am using both the words because I believe myself that practically in all convulsions the cortex of the brain is involved.

15620. But it is the disease in one case and it is the absinthe in the other that is acting. Supposing that the animal were to recover you would not make that animal an epileptic animal?—No, not permanently epileptic, the fit is produced at the time toxically. In the same connection the electrical excitation of the cortex of the brain for the localisation of the different centres is also an absolutely essential part, or should be, of a student's physiological education. Not only do you teach him the geography of the brain, but you again show him another kind of epilepsy, that which is called Jacksonian epilepsy in the most perfect degree; in fact there is no other way of showing it.
